1955-56 AUTRONIC EYE

Cadillac (1955–56)
Chevrolet (1955–56)
Oldsmobile (1955–56)
Pontiac (1955–56)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 AUTRONIC EYE PRODUCTION CHANGES:* Early in production, several major changes were made in the Autronic Eye. These changes include a completely new wiring circuit, Amplifier and Phototube unit. Alternating instead of direct current is used. "Dim" and "Hold" adjustment knobs are now located on underside of amplifier (1954 and Early 1955 "Dim" adjustment was on phototube unit).

►*1955 ADJUSTMENT CAUTIONS:* Early 1955 "Dim" and "Hold" adjustments are made differently than later 1955 adjustments. *For early 1955 adjustments see "1954 Autronic Eye", later 1955 adjustments, see below. NOTE*–There is a possibility that minor circuit changes were made during the model year. It is suggested that reference be made to printed circuit diagram, located on inside of amplifier cover, before performing any service operations on the autronic eye.

DESCRIPTION: Similar in design and operation to previous models. *See Changes above.*

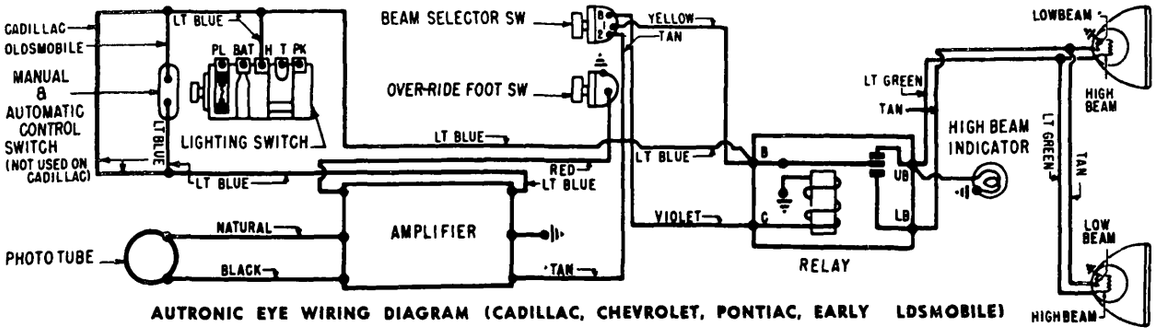
TESTING: Test for "Hold" Sensitivity and "Dim" Sensitivity are made as follows.

►*NOTE: For early 1955 Autronic Eye Tests, see "1954 Autronic Eye". See Changes, Cautions, Corrections above.*

Hold Sensitivity Test (Later Units): *CAUTION–The "Autronic Eye" develops 800 volts. Turn headlamps "OFF" before removing cover from Phototube unit.*

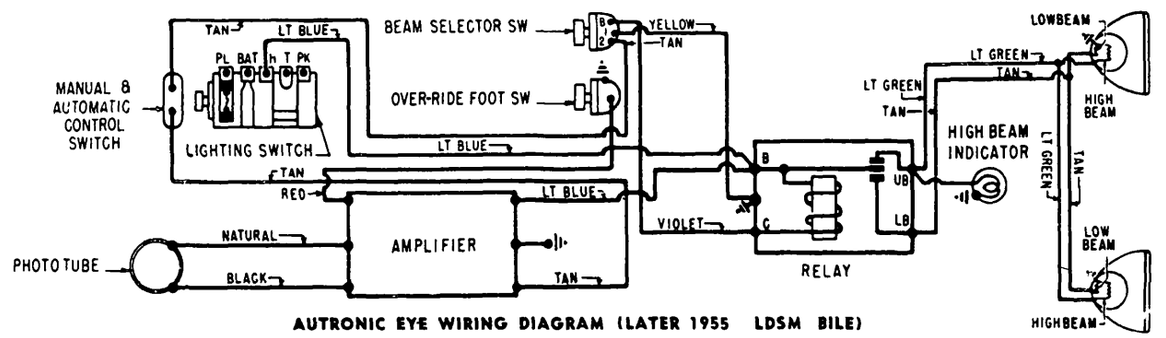
1) Install Aiming Device AE-4.

2) Turn headlamps "ON" and **wait at least four minutes** for amplifier to stabilize. Set standard foot dimmer switch to "Automatic" position. *(NOTE–*Headlamp switch provides "Automatic" and "Manual" controls. With switch set to "Automatic" upper beam will be on).



3) Turn Zero Corrector on face of meter until meter pointer is on zero set line. Turn Intensity Rheostat of tester counter-clockwise. Insert tester connector into cigar lighter receptacle. *CAUTION–*Push straight in.

4) Check car battery voltage. If less than 12 volts, operate engine at fast idle while making sensitivity tests and adjustments



5) Turn tester Selector Switch to "Dim" position (Be sure to use proper "Dim" position for clear or tinted windshield). Turn Intensity Rheostat all the way clockwise to end of adjustment to obtain a lower beam. Turn tester Selector Switch to "Hold" position.

6) **Slowly** turn Intensity Rheostat counter-clockwise just to point where headlamps switch to upper beam. Meter pointer should now read in the "Hold" Sensitivity Adjustment Bar on meter scale. To adjust, see "Hold Sensitivity Adjustment" below.

CONTINUED ON NEXT PAGE

AUTRONIC EYE WIRING DIAGRAM (CADILLAC, CHEVROLET, PONTIAC, EARLY LDSMOBILE)

AUTRONIC EYE WIRING DIAGRAM (LATER 1955 LDSM BILE)

1955-56 AUTRONIC EYE (C ntinu d)

Dim Sensitivity Test (Later Units): 1) Rotate Intensity Rheostat completely counter-clockwise. Turn Selector Switch to "Dim" position. Headlamps should now be on upper beam.
2) Turn Intensity Rheostat **slowly** clockwise, stopping at the exact point where headlamps switch to lower beam. Meter pointer should read within "Dim" Sensitivity Adjustment Line. To adjust, see "Dim Sensitivity Adjustment" below

ADJUSTMENTS: *NOTE–For early 1955 "Dim" and "Hold" Sensitivity Adjustments, see "1954 Autronic Eye".*

Aiming Adjustm nts: Replace Phototube cover with Aiming Device AE-4 *(CAUTION–*Turn lights "OFF", before removing cover). With car at curb weight, tire pressures correct, place car on floor, level within ¼" fore and aft. To adjust vertically, adjust aiming dial to number stamped on name plate of Phototube unit, then adjust aiming screw until bubble is centered in level. To adjust horizontally, aim over sights of Phototube unit. Adjust unit so it is aimed at a point within 4" of line parallel to centerline of car with car 25 ft from aiming point

H ld Sensitivity Adjustm nt (Later Units): *NOTE–*This adjustment must be made **before** the "Dim Sensitivity Adjustment" is made

1) Turn "Hold" Adjustment (on underside of amplifier) clockwise to end of adjustment. Rotate Intensity Rheostat all the way clockwise.

2) Turn Selector Switch momentarily to "Dim" position to switch lights to lower beam, then switch back to "Hold" position *(NOTE–*If lights do not switch to lower beam, "Dim" control must be turned clockwise to end of adjustment and then readjusted after "Hold" adjustment is correct).

3) Adjust tester Intensity Rheostat until meter pointer is in center of "Hold" Sensitivity Bar.

4) Turn "Hold" control counter-clockwise **slowly** just to point where headlamps switch to upper beam.

5) Rotate tester Intensity Rheostat clockwise to end of travel, then turn Selector Switch momentarily to "Dim" position and back to "Hold" (Headlamps should now be on lower beam)

6) Recheck "Hold" adjustment by turning Intensity Rheostat **slowly** counter-clockwise just to point where lamps switch to upper beam. Meter pointer should now read in "Hold" Sensitivity Adjustment Bar if adjustment correct, If not, repeat procedure starting with with Step 1).

Dim Sensitivity Adjustment (Later Units): *NOTE–*"Hold Sensitivity Adjustment" must be made before making this adjustment.
1) Rotate "Dim" control completely counter-clockwise.
2) Momentarily turn tester "OFF", then back to "Dim" position (Headlamps should now be on upper beam).
3) Adjust Intensity Rheostat until meter pointer reads in the right hand edge of the "Dim" Sensitivity Adjustment Line.
4) **Slowly** rotate "Dim" control clockwise just to point where headlamps switch to lower beam **Do not go beyond this setting.**
5) Turn tester Intensity Rheostat completely counter-clockwise, then momentarily turn tester "OFF" and back to "Dim" Rotate Intensity Rheostat **slowly** clockwise just to point where headlamps switch to lower beam. If adjustment correct, meter pointer will read within "Dim" Sensitivity Adjustment Line If not, repeat Steps above
6) **Turn headlamps "OFF",** disconnect tester from cigar lighter receptacle Remove tester and Aiming Device from Phototube unit. Replace lens, cover, and screws

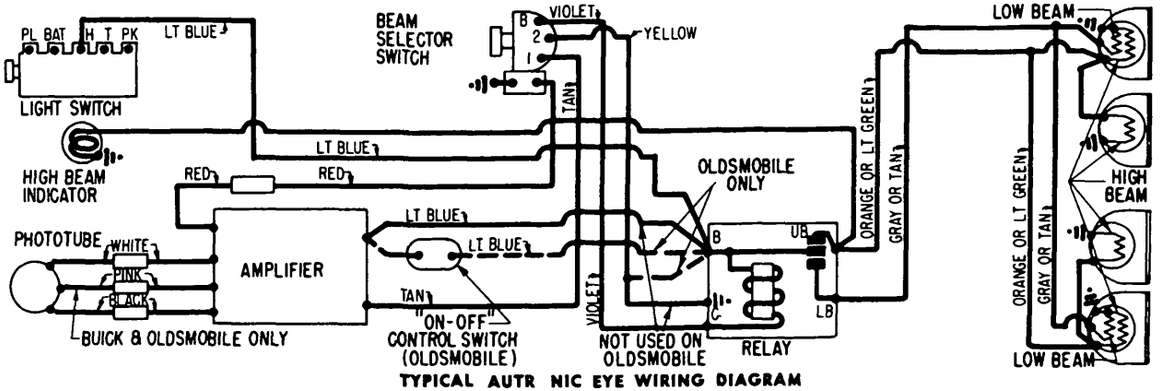
1957-59 AUTRONIC EYE

Buick (1957-59)
Cadillac (1957-59)
Chevrolet (1957-59)
Linc ln & Contin ntal (1957-59)
M rcury (1957-58)
Oldsmobile (1957-59)
P ntiac (1957-59)

►CHANGES, CAUTIONS, CORRECTIONS

►*1958 BUICK WIRING NOTE* Some cars have blue wire from foot dimmer switch to power relay instead of yellow wire spliced into blue wire from amplifier

►*1958 BUICK (Early), CHEVROLET, PONTIAC AMPLIFIER CAUTION* On cars with power windows disconnect battery ground strap when working on amplifier Power window relay has exposed "BAT" terminal and is very close to amplifier To facilitate amplifier removal move window relay to one side



►*1958 CHEVROLET SENSITIVITY RELAY REMOVAL CAUTION.* Relay is sealed in housing and suspended from housing by two screws Removing screws will cause relay to fall to bottom of housing and relay replacement will be necessary

►*1958 OLDSMOBILE HEADLIGHTS REMAINING ON LOW BEAM CORRECTION* Caused by sensitivity relay points sticking together when headlights dimmed manually and autronic eye in "OFF" position On early cars can be corrected by breaking off brass ground tab on headlight switch Later cars do not have tab

DESCRIPTION: Similar in design and operation to previous models. A combination foot operated dimmer switch and Autronic Eye "over-control" switch is used which automatically controls the headlamps when switch is in the "high" beam position. The "low" beam position provides constant low beam operation. When the foot switch is in "high" beam, or automatic position, it can be used as an override switch to manually turn on the "high" beams by applying a slight downward pressure on top of switch. On Oldsmobile models, a separate "On-off" switch located in the headlamp switch, controls the Autronic Eye in addition to the dimmer switch. On all models, the dimmer switch must be in the "high" beam position before lights will operate automatically. *NOTE* - Some cars have a driver sensitivity control on phototube unit This gives driver a certain amount of control for unusual conditions such as heavy snow or fog Adjustment toward "F" (Far) increases sensitivity, toward "N" (Near) decreases sensitivity

TROUBLE SHOOTING & DIAGNOSIS: Preliminary Checks - ***NOTE - If unit operates for these tests, adjustment only is needed.*** **Turn unit on in a lighted area and allow 30 seconds warm-up. Place a black cloth over phototube and operate foot switch. Upper beam should be on in one foot switch position. If not, see "Unable To Obtain Upper Beam" below. Remove cloth and operate foot switch. Lights should be on lower beam in both positions. If not, see "Unable To Obtain Lower Beam" below. In one foot switch position, upper beam should go on by depressing foot switch ¼". If not, see "No Overriding Upper Beam" below.**

CONTINUED ON NEXT PAGE

TYPICAL AUTR NIC EYE WIRING DIAGRAM

1957-59 AUTRONIC EYE
(C ntinu d)

Unable To Obtain Upper Beam: Disconnect blue wire from amplifier and operate foot switch. If upper beam does **not** go on, foot switch, power relay, or wiring is faulty. If upper beam goes on, disconnect white wire from amplifier. If upper beam goes on in one foot switch position, phototube is faulty. If upper beam does **not** go on, amplifier is faulty.

Unable To Obtain Lower Beam: With blue wire to amplifier disconnected, operate foot switch. If lower beam **not** obtained, foot switch, power relay, or wiring is faulty. If lower beam **is** obtained, replace blue wire, remove red wire and operate foot switch. If lower beam obtained in **both** positions, foot switch is faulty. If lower beam **not** obtained, disconnect pink wire. If lower beam obtained on both foot switch positions, amplifier is faulty.

No Overriding Upper Beam: Disconnect foot switch red wire and short to ground. If upper beam obtained, foot switch is faulty. If upper beam **not** obtained, wire continuity or amplifier is faulty.

TESTING & ADJUSTING: *CAUTION - The Autronic Eye unit develops 800 volts. Make sure the headlights are OFF before removing cover from phototube unit.*

►*1959 AIMING DEVICE NOTE:* On following cars new aiming devices are used for 1959 models. Use in accordance with instructions furnished (see AE-4 Note below). **Buick** - J-5297-01; **Cadillac** - J-5297-01 (Early), J-7821 (Later - After Engine No. 008790); **Oldsmobile** - J-5297-A or AE-2.

►*AIMING DEVICE AE-4 INSTALLATION NOTE:* Remove cover from phototube and install the aiming device in accordance with instructions enclosed with the unit. Adjust aiming dial on the Aiming Device to the number stamped on name plate at bottom side of phototube unit (number is a single digit located directly below the serial number).

V rtical Aiming Adjustment: Position car on a level floor (level within ¼" fore and aft of car), then rock car gently to equalize springs. Install Aiming Device AE-4 (see installation note above). Adjust phototube unit aiming screw with an Allen Wrench (screw is located on bottom of phototube unit at rear edge of pedestal), until bubble in aiming device is centered in level. *(NOTE* - If phototube unit is aimed too low, reflections from the car's own headlamps will cause them to be held on "low" beam. Also, the phototube unit must be aimed as low as possible to provide maximum tolerance for car loading).

Horizontal Aiming Adjustment: Place two pieces of tape or chalk marks approx. 23-24½" apart on wall or screen at hood level height. With car placed 25 ft. from wall or screen, align centerline of hood with the right hand tape or chalk mark. Install Aiming Device AE-4, then aim over sights to left hand tape. If phototube unit is aimed more than 4" to right or left of left hand tape, reset phototube by loosening mounting stud nut under instrument panel. If necessary, one of the mounting holes in instrument panel may be elongated. *NOTF* - On **Buick, 1957-58 Lincoln & Mercury, adjustment is made by an Allen screw on phototube unit.**

Hold Sensitivity Test: Install Aiming Device (see above), then turn headlamps ON and **wait at least five minutes** for amplifier to stabilize. *NOTE - On Oldsmobile, it will also be necessary to turn Autronic Eye switch ON.* Set foot dimmer switch to "high" beam which also places Autronic Eye in automatic position. Turn "zero corrector" on face of meter until meter pointer is on zero set line. Turn "intensity rheostat" of tester counterclockwise, then insert tester connector into cigar lighter receptacle (necessary only on Sun and AE-2 Testers). Operate engine at fast idle while making sensitivity tests and adjustments. Turn "tester selector switch" to DIM position (be sure to use proper DIM position for clear or tinted windshields). Turn "intensity rheostat" all the way clockwise to end of adjustment to obtain a lower beam. Turn "test selector switch" to HOLD position. Slowly turn "intensity rheostat" counterclockwise just to point where headlamps switch to "high" beam. Meter pointer should now read in the "hold sensitivity adjustment bar" on the meter scale. If not within this range, adjust as follows:

Adjustment - *(NOTE - Both the HOLD and DIM adjustment controls are located on the underside of the amplifier unit and each is identified by a stamp on the amplifier cover. THE HOLD SENSITIVITY ADJUSTMENT MUST BE CORRECTLY MADE BEFORE ADJUSTING THE DIM SENSITIVITY.* Turn the HOLD adjustment clockwise to the end of its travel, then rotate "intensity rheostat" all the way clockwise. Turn selector momentarily to DIM position to switch lights to lower beam, then switch back to HOLD position. *NOTE - If lights do not switch to lower beam, DIM adjustment control must be turned clockwise to end of adjustment, then readjusted after HOLD adjustment is correct.* Adjust tester "intensity rheostat" until the meter pointer is at right hand edge of "hold sensitivity bar". Turn the HOLD adjustment control (on amplifier) counterclockwise SLOWLY just to point where headlamps switch to upper beam. Rotate tester "intensity rheostat" clockwise to end of travel, then turn "selector switch" momentarily to DIM position and back to HOLD. (Headlamps should now be on lower beam). Recheck HOLD adjustment by turning "intensity rheostat" SLOWLY counterclockwise just to point where headlamps switch to upper beam. Meter pointer should now be aligned with the right hand edge of HOLD adjustment green bar if adjustment is correct. If not, repeat the above procedure.

Dim Sensitivity Test: Rotate tester "intensity rheostat" completely counterclockwise. Turn "selector switch" to DIM position. Headlamps should now be on upper beam. Turn "intensity rheostat" SLOWLY clockwise, stopping at the exact point where the headlamps switch to lower beam. Meter pointer should be within the "dim sensitivity adjustment" line. If not properly adjusted, proceed as follows:

Adjustment - *(NOTE - Do not make this adjustment until after "Hold Sensitivity Adjustment" is made).* Rotate DIM control fully counterclockwise. Momentarily turn tester OFF, then back to DIM position. Headlamps should now be on upper beam. Adjust "intensity rheostat" until meter pointer reads in the right hand edge of "dim sensitivity adjustment" line. SLOWLY rotate DIM control clockwise just to point where headlamps switch to lower beam. DO NOT GO BEYOND THIS SETTING. Turn tester "intensity rheostat" completely counterclockwise, then momentarily turn tester to OFF and back to DIM. Rotate tester "intensity rheostat" SLOWLY clockwise just to point where headlamps switch to lower beam. Meter will read within "dim sensitivity adjustment" line if adjustment is correct. If not, repeat the above adjustments. Remove tester, and Aiming Device AE-4. Replace lens, cover and screw.

1955-56 LINCOLN & MERCURY AUTOMATIC HEADLIGHT DIMMER

Linc ln & M rcury (1955–56)

►*1957-59 MODEL NOTE: See "1957-59 Autronic Eye" for data on th s mod ls.*

DESCRIPTION: The Automatic Headlight Dimmer is an electronic device that automatically switches headlamps between the upper and lower beams in response to light from an approaching car and to the tail lights on cars being overtaken. Unit consists of switch and control assemblies.

OPERATION: With headlights turned on, and the pilot light indicating automatic control, light striking the photo-multiplier tube of the control assembly causes generation of a weak electrical current. This current is electronically amplified and used to actuate relays in the switch assembly. The relays then switch headlights from high to low beam. When light source is removed, headlights return to high beam. Foot dimmer switch can be used to override automatic control at any time. When foot switch is pushed, the circuit switches off of automatic and green indicator light in control head goes out. Foot switch must be pushed again to return to automatic control. High beam indicator light indicates actual position of headlight beam whether circuit is on manual or automatic

Switch Ass mbly: A three position switch, located on left side of control head assembly has positions marked "FAR", "NORM" and "NEAR" With switch on "NORM" position, working against standard rated oncoming bulbs on low beam, headlights will dim when approaching lights are 1100-1200 ft. away. Changing switch to either "FAR" or "NEAR" changes dimming distance by approximately 200 ft. in direction indicated.

OPERATIONAL CHECK: Switch the circuit to automatic (green pilot light on), block out light to control tube *NOTE*–Light can be effectively blocked by covering control head lens with one hand and the opening about the "FAR-NORM-NEAR" switch with the other (this procedure will not work in bright sunlight as enough light passes through the hands to cause tube to hold headlights on low beam) With lens covered, headlamps will switch to high beam automatically If they do not, unit is not functioning properly *CAUTION*– Unit developes high operating voltages. Control head is normally grounded to prevent high voltage danger. Red wire at switch assembly connector must be disconnected before removing head, thus breaking ground connection

TROUBLE DIAGNOSIS: Leveling–With headlight circuit on automatic, with dim and hold sensitivity adjustments correct, the head pointing downward will result in reduced dim and hold distances, and cause automatic circuit to hold low beam from reflection of its own headlights. If head aimed too high, dim and hold distances will be reduced, sensitivity to tail lights will be reduced and, in extreme cases, unit will not dim on tail lights

Dim Sensitivity: With head properly leveled, insufficient dim sensitivity will result in reduced dimming distance. Too much dim sensitivity will result in increased dimming distance.

Hold Sensitivity: With head properly leveled, and dim sensitivity properly adjusted, insufficient hold sensitivity will result in excessive high beam operation and excessive hold sensitivity will cause automatic circuit to operate excessively on low beam and, in extreme cases, system will lock on low beam because of reflection from its own headlights

TROUBLE SHOOTING: Unit Will Not Dim Within Range Of Dim Sensitivity Adjustment–Defective phototube (control assembly), defective control tube, defective circuit

Unit Will Not Respond To Hold Adjustment: Defective control tube, defective circuit

Unit Stays On Low B am In Aut matic Positi n: Head not level, fuse blown, vibrator, ballast tube, control head, or control tube defective.

Pilot Light In Head Inoperative: Light defective.

Unit Dims Automatically, Then Locks In Low B am: Head not level; control tube defective, improper headlight alignment (dimming on vehicles own headlights).

►*CONTROL TUBE CHECK:* Disconnect red and green wires at switch assembly connector and use a 45 volt dry cell to make test Ground positive battery terminal and connect negative terminal to switch assembly end of green lead with a jumper wire If headlamps dim, switch assembly is satisfactory and control tube should be replaced. If lights do not dim, replace switch assembly.

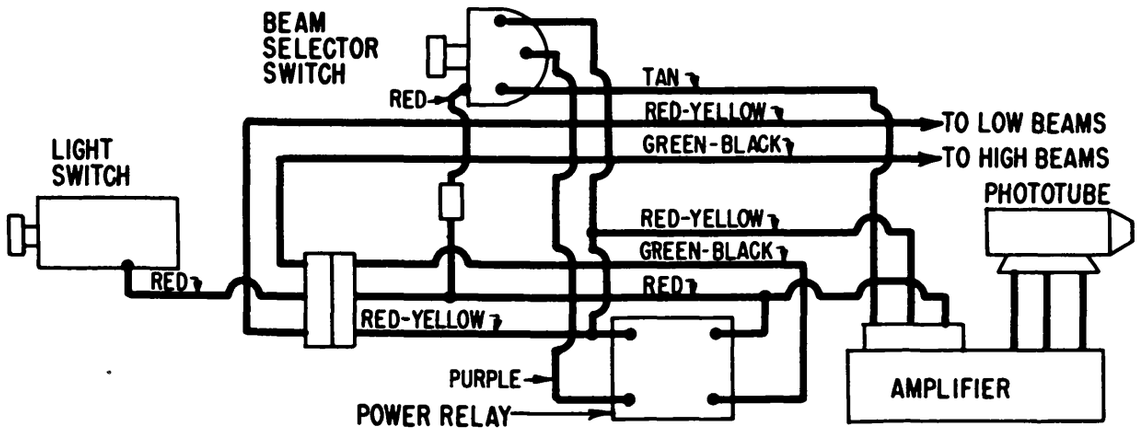
ADJUSTMENTS: Make all adjustments according to instructions furnished by the test equipment manufacturer and note the following

Fine Sensitivity: Accessible by removing rubber plug in the cover. It varies "Dim" and "Hold" distances simultaneously through a limited range. To increase, turn adjustment screw clockwise.

Course Sensitivity: Located close to edge of chassis under cover. It varies "Dim" and "Hold" distances simultaneously over a broad range and must be used when fine sensitivity control will not provide desired results Turn adjustment screw clockwise to increase range

Hold Control: Located in center of chassis under cover. It varies the "Hold" distance independent of the "Dim" distance To increase the "Hold", turn adjustment screw clockwise.

Leveling Control Head: To level control head, release locking screw with 1/8" Allen wrench and adjust phototube unit by hand until bubble is centered in spirit level



1960 LINCOLN AUTOMATIC HEADLIGHT DIMMER

Lincoln & Continental (1960)

DESCRIPTION: Similar in design and operation to previous models. Headlights are automatically controlled by phototube unit on instrument panel. An override foot control switch is located to left on drivers floor board. Headlights are on automatic control when switch is on high beam and on constant low beam when switch is on low beam. To momentarily obtain high beam for signaling oncoming vehicles or for checking automatic position of switch, depress foot switch part way. A drivers sensitivity control (Driver Control) is located on Phototube Unit to permit driver limited control of "Dim" and "Hold" sensitivity. A detent position (control knob pointing up and in line with center ridge) is for normal sensitivity. Rotate knob clockwise (toward "F") to increase sensitivity, counterclockwise to decrease sensitivity.

TESTING & ADJUSTING: Preliminary Tests - 1) Place car in a lighted area and turn lights to full **ON** position. Lights should be on low beam regardless of foot switch position.

CONTINUED ON NEXT PAGE

LINCOLN & CONTINENTAL AUTOMATIC HEADLIGHT DIMMER WIRING DIAGRAM

1960 LINCOLN AUTOMATIC HEADLIGHT DIMMER (C nt.)

2) Depress foot switch part way. Light should change to upper beam and then back to lower beam when foot switch is released.

3) Place hand or dark cloth over phototube unit. Lights should switch to upper beam if foot switch is on automatic position. Remove cloth and lights should change back to lower beam.

NOTE - When steps 1,2 and 3 are **not** correct, proceed with "Vertical", "Horizontal", "Dim" & "Hold" Sensitivity Tests below.

4) All connections must be tight and properly made. Use known good individual components for substitutes for quick and easy correction procedure.

AIMING ADJUSTMENT: *AIMING EQUIPMENT NOTE: Use Electronic Headlight Control Tester, Model AD or Tester No. 5297-01 and Aiming Device No. 5.* With car unloaded, trunk empty, tire pressure correct, and with gas tank at least half full, locate car on level floor (floor must be level within ¼" fore and aft of car). Equalize springs by rocking car gently. *CAUTION - Turn headlights off before removing cover from phototube unit.* Loosen Allen screw at each side of phototube unit and remove cover, then replace cover with Aiming Device No. 5 and Control Tester Model AD. *NOTE - Oval type adapter ring must be used. DO NOT USE square lens aiming device formerly required.* Tighten cover screws, then insert test lamp into phototube base by inserting locator ring in lens slot. *CAUTION - Lens locator in phototube unit base must fit in locator ring notch. Do not remove amber filter and mask.*

Horizontal Aim: Centerline of Phototube Unit must be aimed parallel to the horizontal centerline of car. Check aim as follows:

1) Locate car approximately 25 feet from vertical wall or screen. Sight down car hood and place a piece of tape vertically on wall at hood height to represent car centerline.

2) Measure distance between centerline of Phototube and center of car windshield. Place second tape vertically at this distance to left of car centerline. Use the two sights on Aiming Device to determine alignment.

3) When horizontal aim is not correct, remove instrument cluster hood and loosen Phototube mounting bracket. Rotate Phototube unit until horizontal aim is correct. Tighten mounting bracket nut and recheck adjustment.

Vertical Aim: Note number stamped on name plate and adjust dial of Aiming Device to this number. Use Allen wrench (inside cover) to adjust aiming screw at rear of Phototube base to bring bubble into center in level. *NOTE* - Aim Phototube low enough to provide maximum tolerance for car loading.

Hold Sensitivity Test: *NOTE - "Hold" sensitivity must be properly adjusted before adjusting "Dim" Sensitivity. Cover Phototube Unit with black cloth for tests and adjustment.*

1) Set Driver Control to detent position. Operate engine at fast idle for tests and adjustment. Turn headlights ON and allow five minutes for amplifier to stabilize.

2) Set foot switch to automatic position (upper beam will be ON). Turn zero corrector on face of meter unit until meter pointer is on "O" set line. Turn "Intensity" rheostat of tester all the way counterclockwise.

3) Switch ground polarity toggle switch to negative (-) position. Insert tester connector into cigar lighter receptacle. *NOTE* - Tester 5287-01 has it own power supply. Model AD Tester provides a selector switch for setting meter for clear or tinted windshield while Tester No. 5297-01 provides separate meter scales for clear and tinted windshields.

4) Turn selector or "Dim"-"Hold" switch to "Dim" position. Turn tester intensity rheostat all the way clockwise to end of adjustment.

5) If lights DO NOT switch to lower beam, the amplifier "Dim" adjustment control must be turned completely clockwise and then readjusted after "Hold" adjustment is correct.

6) Turn tester selector switch to "Hold" position. Then slowly and carefully turn intensity rheostat counterclockwise just to point where headlights switch to upper beam. Meter pointer should now read on right hand edge of the "Hold" sensitivity adjustment on meter scale.

Hold Sensitivity Adjustment: "Hold" and "Dim" sensitivity adjustments are slotted for screwdriver adjustment and located at front of amplifier unit. For access to adjustments, remove center instrument panel lower access cover in back of radio.

1) Rotate amplifier "Hold" control completely clockwise. Rotate tester intensity rheostat all the way clockwise. Turn selector or "Dim"-"Hold" switch momentarily to "Dim" position to switch lights to lower beam, then switch back to "Hold" position.

2) Adjust intensity rheostat until meter pointer is at right hand edge of green "Hold" sensitivity bar.

3) Turn amplifier "Hold" control slowly counterclockwise just to point where headlamps switch to upper beam. Rotate tester intensity rheostat clockwise to end of travel, then turn selector switch momentarily to "Dim" and back to "Hold".

4) Recheck "Hold" adjustment by turning intensity rheostat slowly and carefully counterclockwise just to point where headlights switch to upper beam. Meter pointer should read in "Hold" sensitivity bar if adjustment is correct. If not, repeat procedure.

Dim Sensitivity Test: "Dim" sensitivity should not be adjusted until after "Hold" sensitivity is properly adjusted.

1) Rotate tester intensity rheostat completely counterclockwise. Turn selector or "Dim"-"Hold" switch to "Hold" position and then back to "Dim" position. Headlights should be on upper beam.

2) Turn tester intensity rheostat clockwise slowly just to point where headlamps switch to lower beam. Meter pointer should now read in the **black** "Dim" sensitivity adjustment line. If not, proceed to "Dim Sensitivity Adjustment".

Dim Sensitivity Adjustment: 1) Adjust "Intensity" rheostat until meter pointer reads in right hand edge of "Dim" sensitivity adjustment line. Rotate amplifier "Dim" control counterclockwise to end of adjustment.

2) Momentarily turn tester selector switch to OFF position so that headlights are on upper beam, then turn switch back to "Dim" position.

3) Carefully and slowly rotate amplifier "Dim" control clockwise just to point where headlights switch to lower beam. **Do not go beyond this p int.**

4) Turn tester "Intensity" rheostat slowly clockwise just to point where headlights switch to lower beam. Meter will read within "Dim" sensitivity line if adjustment is correct. If not, repeat steps 1 through 4.

5) Turn off headlights, remove equipment, replace cover and lens assembly and tighten Allen setscrews.

G.M. GUIDE-MATIC HEADLIGHT DIMMER

Buick (1960)
Cadillac (1960)
Chevrolet (1960)
Oldsmobile (1960)
Pontiac (1960)

DESCRIPTION: Similar in design and operation to previous models. A combination foot operated dimmer switch and Guide-Matic "over-control" switch is used which automatically controls headlights when switch is in the "high" beam position. The "low" beam position provides constant low beam operation. When the foot switch is in "high" beam or automatic position, it can be used as an override switch to manually turn on the "high" beams by applying a slight downward pressure on top of switch. On Oldsmobile models, a separate "on-off" switch located in headlight switch (which has a 9 amp. fuse for protection of circuit), controls the Guide-Matic in addition to the dimmer switch. On all models, the dimmer switch must be in the "high" beam position before lights will operate automatically. A sensitivity control on phototube unit gives driver a certain amount of control for unusual conditions such as heavy snow or fog. Adjust toward "F" (Far) increases sensitivity, toward "N" (Near) decreases sensitivity. Courtesy salute section of Guide-Matic switches the headlights from upper to lower beam in a two-step action. When headlights are switched to "low" beam position, upper beams will remain on approximately a second at reduced candlepower to indicate car is equipped with Guide-Matic.

►*CONVERSION TO MANUAL CONTROL:* When Guide-Matic cannot be serviced immediately, lights can be converted to manual switch operation by disconnecting phototube unit connector from amplifier. It may be necessary to remove foot switch from floor and disconnect amplifier harness from car wiring harness and install car wiring harness on foot switch.

TROUBLE SHOOTING & DIAGNOSIS: Preliminary Checks - *NOTE - If unit p rat s f r th se t sts, adjustment only is needed.* Turn unit on in a lighted area and allow 30 seconds warm-up. Place a black cloth over phototube and operate foot switch. Upper beam should be on in one foot switch position. If not, see "Unable To Obtain Upper Beam" below. Remove cloth and operate foot switch. Lights should be on lower beam in both positions. If not, see "Unable To Obtain Lower Beam" below. In one foot switch position, upper

CONTINUED ON NEXT PAGE

G.M. GUIDE-MATIC HEADLIGHT DIMMER (C nt.)

beam should go on by depressing foot switch ¼". If not, see "No Overriding Upper Beam" below.

Unabl T Obtain Upp r B am: With "Hold" control in center of rotation and upper beam obtained, adjustment is necessary (see below). If no upper beam obtained, disconnect phototube from amplifier. If upper beam goes on, phototube is faulty. If upper beam **does not** go on, disconnect foot switch wiring from switch and connect car wiring from amplifier to switch. Operate foot switch. If lamps change beams, amplifier is faulty. If lamps **do n t** change beams, foot switch or car wiring is faulty.

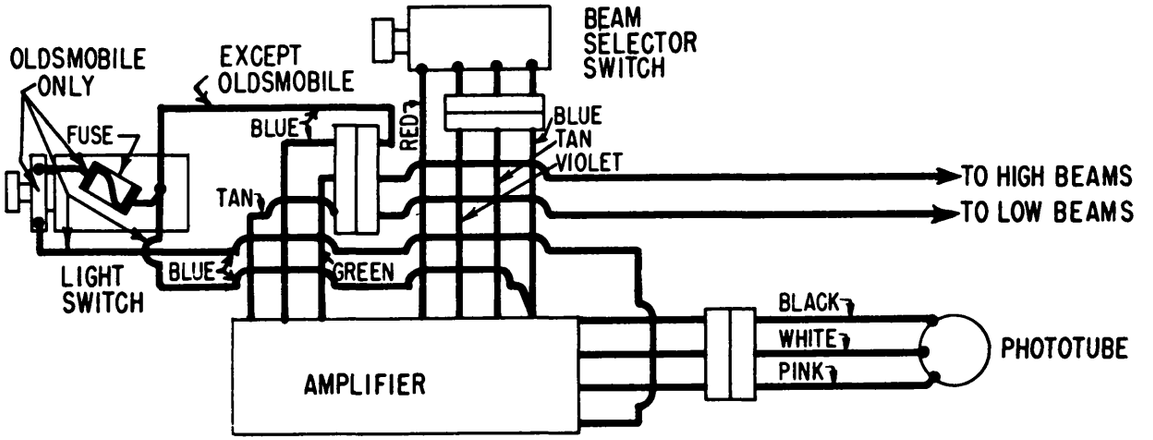
Unabl T Obtain Lower Beam: Ground white wire between phototube and amplifier (remove phototube cover for access). If beams change, phototube is faulty. If beams **d n t** change, remove red wire from switch. If beams change, foot switch is faulty. If beams **do not** change, remove foot switch wiring and connect car wiring from amplifier t o switch. Operate switch. If beams change, amplifier is faulty. If beams **do not** change car wiring is faulty.

N Ov rriding Upper B am: Ground red wire from foot switch. If override obtained, foot switch is faulty. If override **n t** obtained, amplifier is faulty.

TESTING & ADJUSTING: *NOTE* - Use Guide-Matic Tool J-8465 (Buick, Cadillac, Pontiac); Level J-8465-20, Test Lamp & Adapter J-8662 and Tester AE-2 (Oldsmobile) for installing, testing, and adjusting Guide-Matic headlight dimmer.

Vertical Aiming Adjustment: *CAUTION - Unit must be aim d as low as p ssible to provide tolerance for car l ading. Aim unit with car unloaded, trunk empty except for spar tir , gas tank at least half-full and with tires at c rrect pressure.*

1) Locate car on level floor (1/4" fore and aft of car).



2) Rock car sideways to equalize springs. On Cadillac with Air Suspension, idle engine to insure car levelness.

3) Set Aiming Device on Phototube Unit. *NOTE* - Three points on Aiming Device must rest on top of Phototube Unit and Aiming Device must be touching front of Phototube Unit.

4) Note number stamped on Drive Control knob then adjust aiming dial until corresponding number is under pointer.

5) Adjust vertical aiming screw on Phototube Unit until bubble is centered in level.

Dim and Hold Sensitivity T st: *CAUTION - Cover Ph totube Unit with black cloth. T sts or adjustm nts should be made with Ph totube unit below 100°F. If car has be n in th sun, place it in cool spot for appr ximately on h ur b fore check is mad .*

"GUIDE-MATIC" HEADLIGHT DIMMER WIRING DIAGRAM (TYPICAL)

1) Set Driver Control to "detent" position and install tester lamp. Start engine and operate at fast idle while making adjustments.

2) Turn headlights "ON" and wait five minutes for Amplifier Unit to stabilize. Turn Zero corrector on face of meter until meter pointer is on zero set line then connect battery leads of tester unit to cigar lighter receptacle (Oldsmobile), to battery terminals (Others).

3) For Dim Sensitivity, rotate tester Intensity Control completely counterclockwise. Turn Selector on Dim-Hold Switch to "HOLD" position and then back to "DIM" position. Headlamps should be on upper beam.

4) Turn test Intensity Control clockwise slowly just to point where headlamps switch to lower beam. Meter pointer should now read in Black Sensitivity Range on meter scale. If not proceed to "HOLD" Sensitivity Adjustment, under Hold and Dim Sensitivity below.

5) For Hold Sensitivity, turn Intensity Control all the way clockwise. Turn selector or Dim-Hold Switch to "DIM" position and back to "HOLD" position to obtain a lower beam.

6) Slowly turn Intensity Control counterclockwise just to point where headlamps switch to upper beam. Meter pointer should now read in the Green "HOLD" Sensitivity range on meter scale. If not, proceed to "Hold" Sensitivity Adjustment under Hold and Dim Sensitivity below.

Hold and Dim Sensitivity Adjustment: *CAUTION - "HOLD" Sensitivity must be made properly before adjusting "DIM" Sensitivity. Phototube unit must be covered with a black cl th during adjustm nts.*

1) Complete Steps 1 and 2 under Dim and Hold Sensitivity Test. *NOTE* - Dim and Hold Sensitivity Controls are located on side of Amplifier Unit (slotted for screwdriver adjustment). For access, remove plug from door hinge pillar.

2) **For Hold Sensitivity,** rotate Amplifier Hold Control completely clockwise. Rotate tester Intensity Control Control all the way clockwise. Turn Selector (Dim-Hold Switch) momentarily to "DIM" position to switch lights to lower beam, then switch back to "HOLD" position.
NOTE - If lights do not switch to lower beam, the amplifier Dim Control must be turned completely clockwise and then readjusted after "HOLD" adjustment is correct.

3) Adjust Intensity Control on tester slowly counterclockwise until meter pointer is on HOLD SENSITIVITY adjustment line. Turn Amplifier Hold Control slowly counterclockwise just to point where headlamps switch to upper beam. Do not go beyond this setting. Recheck Sensitivity, Steps 5 and 6 under Dim and Hold Sensitivity tests, above.
NOTE - Dim Sensitivity should not be adjusted until "HOLD" Sensitivity is properly adjusted.

4) **For Dim Sensitivity,** rotate Amplifier "DIM" Control completely counterclockwise. Momentarily turn Dim-Hold Switch on tester to "HOLD" then back to "DIM" position to obtain upper beam.

5) Adjust tester Intensity Control until meter pointer is at Dim Sensitivity Adjustment Line then slowly rotate Amplifier Dim Control clockwise just to point where headlamps switch to lower beam. DO NOT go beyond this setting.

6) Recheck Sensitivity, Steps 3 through 6 under Dim Sensitivity, above. If Sensitivity is not correct, repeat repeat adjustment procedure. If correct, turn off headlights, disconnect tester, remove Tester lamp from Phototube Unit and reinstall plug in door hinge pillar.

ELECTRIC DIRECTION SIGNALS

DESCRIPTION & OPERATION: All direction signal systems are similar in design and operate in the same manner except that various types of indicator circuits are used as listed below. *See typical wiring diagrams below.* The Flasher "Power Source" is usually the "IGN" or "ACC" terminal of the ignition switch so that the direction signals are operative only with the ignition turned on, and a fuse or circuit breaker is connected in this "Power Source" line to protect the direction signal circuits. *See individual Car Model Wiring Diagrams for complete Direction Signal circuit.*

Double "Cross-Over" Type Indicators - Indicators are connected in parallel to the "P" terminal of the flasher and each indicator circuit is completed to ground through the Front Direction Signal on the **opposite** side of the car (Right indicator connected to left signal, Left indicator connected to right signal).

Single "Cross-Over" Type Indicator - The single indicator is connected directly across or between the two Front Direction Signals. The indicator will flash when either of the front signals is operating (circuit is fed from the operating signal lead and indicator bulb is grounded through the other signal bulb).

Double "Parallel" Type Indicators - Each indicator is connected in parallel with the Front Direction Signal on the **same** side of the car (Right indicator connected to right signal, Left indicator to left signal) and each indicator bulb is grounded directly.

Single "Parallel" Type Indicator - This circuit not illustrated. The single indicator is connected directly to the "P" terminal of the flasher and the bulb is grounded directly. The indicator flashes whenever the flasher is operating.

TROUBLE SHOOTING: Operate direction signals by placing switch in "Right Turn" and "Left Turn" positions successively and note operation of signal lights and indicators in each position. In normal operation, lights should flash approximately 90 times per minute. *NOTE* - Ignition switch must be "ON" for signal light operation. Diagnose trouble as follows:

1) All Signal Lights and Indicators do not operate - Blown fuse, defective flasher, defective switch, open circuit between ignition switch and flasher or between flasher and switch.

2) One Signal Light does not operate - Burned out bulb or loose wiring connections. Other signal light on same side of car will flash at twice speed. On systems with "Double Cross-Over Type Indicators", both indicators will flash in unison if rear signal bulb burned out; one indicator will operate normally if front signal light on same side is burned out, but will not operate if front signal light on opposite side is burned out. *NOTE* - Indicator will not operate if both front and rear signal light bulbs are burned out.

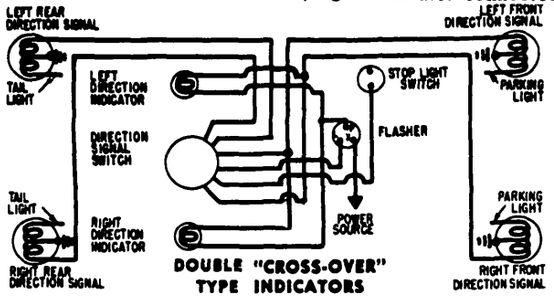
3) One Signal Light op rat s but flash s too fast - The other signal light bulb on same side of car is burned out, or there is high resistance (loose connections or corroded contacts) in circuit.

4) All Signal Lights operat but flash t fast - Faulty flasher or high voltage.

5) All Signal Lights operat but flash sl wly - Faulty flasher, low voltage, or high resistance in circuit.

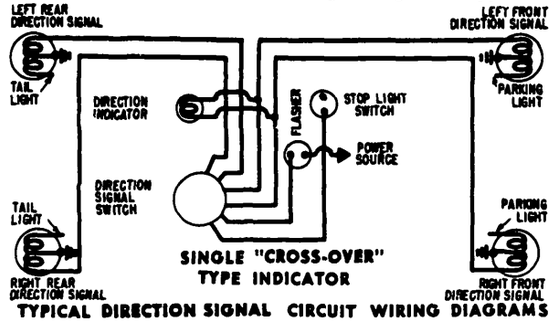
6) Both Indicator Lights flash dimly, at sam tim (faster than normal) - *NOTE - Both indicator lights may appear inoperative.*

Right Turn - Right rear or right front turn signal filament burned out, or lamp base not grounded.



Left Turn - Left rear or left front turn signal filament burned out, or lamp base not grounded.

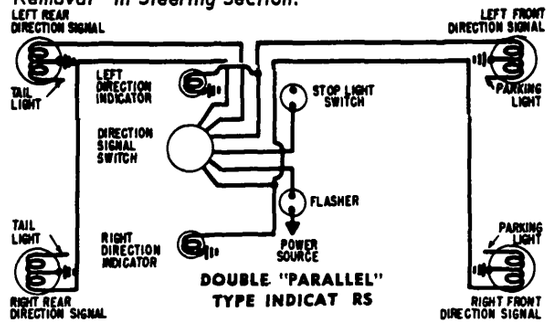
7) Both Indicator Lights flash dimly (at normal frequency) - Indicator lamp section of flasher inoperative or open circuit in wire from flasher to indicator lights.



SERVICING: Flashers cannot be repaired and defective units should be replaced.

Fuse Location & Capacity - *S MISCELLANEOUS ELECTRICAL in individual car m d l data pages.*

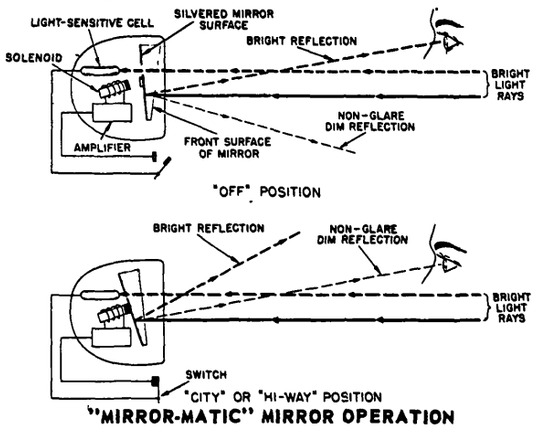
Directional Signal Switch - Located in housing under steering wheel or attached to steering column jacket. For access to switch, *se "St ring Wh l & Horn Ring Removal" in Steering Section.*



DOUBLE "CROSS-OVER" TYPE INDICATORS

SINGLE "CROSS-OVER" TYPE INDICATOR

TYPICAL DIRECTION SIGNAL CIRCUIT WIRING DIAGRAMS



DOUBLE "PARALLEL" TYPE INDICAT RS

CHRYSLER ELECTRONIC REAR MIRROR

Chrysler & Imperial (1959-60)
DeSoto (1959-60)
Dodge & Dodge Dart (1959-60)
Plymouth (1959-60).

DESCRIPTION: An electronically controlled rear view mirror which provides maximum rear vision at night by using bright surface of mirror except when glaring light strikes its surface. Mechanism housed entirely within mirror base and controlled by 3-position switch on mirror bezel. "OFF" position on switch locks mirror in normal "bright" position; "City" position permits less sensitivity to city street lights; "Hi-way" position permits full sensitivity for normal highway conditions.

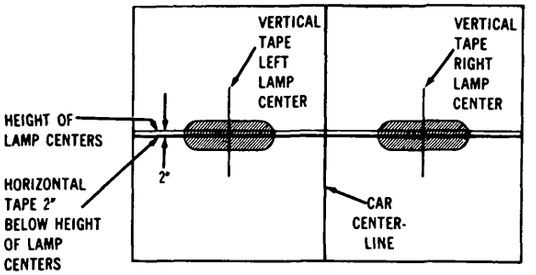
OPERATION: A small photo-electric cell is set in a hole in mirror surface. Light striking cell generates a small current which increases as light intensity increases. When intensity is high enough to cause glare, current actuates a small amplifier and solenoid assembly which pulls mirror upward a few degrees to reflect a dim image into driver's eyes. When light intensity drops below pre-set level, mirror automatically returns to normal "bright" position.

"MIRROR-MATIC" MIRROR OPERATION

DRIVER ADJUSTMENT (Positioning Mirror): With headlights off, loosen locknut at mirror support base and position mirror for best rear viewing and brightest image. Tighten locknut.

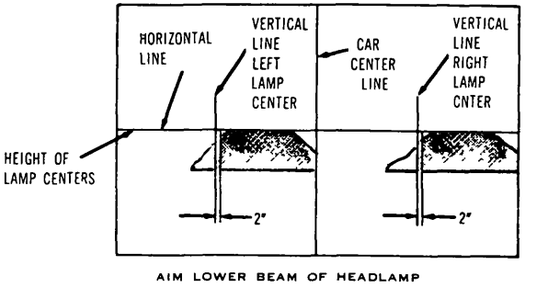
SERVICE ADJUSTMENT: If glare exists in either "City" or "Hi-way" position (mirror does not dim), sensitivity is too low. Raise sensitivity as follows: Remove switch knob by pulling off. Remove mirror bezel, lifting out and up to clear retaining tabs. Move top part of back cover upward and rearward over mirror support just enough to provide access to potentiometer adjusters. To increase sensitivity, turn potentiometer arm marked "City" or "Hi-way" as required, in direction indicated by arrow. To decrease sensitivity, turn arm in opposite direction. Replace cover, bezel and switch knob. Position mirror.

SEALED BEAM HEADLAMPS
(2-HEADLIGHT SYSTEMS)



DESCRIPTION: Sealed Beam Headlamps, as used on cars so equipped, consist of a reflector, lens, and lamp filaments assembled as a single sealed unit. This excludes all dirt and moisture so that the original effciency of the lamp is retained throughout the life of the filaments. When replacement is required, the entire sealed beam unit is discarded and a new unit is installed. No attempt should be made to disassemble the sealed beam unit.

OPERATION: Sealed Beam lamps have double "bar" type filaments (filaments are parallel and slightly offset so that lower "Traffic" beam deflected slightly toward right side of road. Beams are controlled by a Beam Selector Switch on the toe-board in the usual manner.



INSTALLATION & REMOVAL: On all cars, a sub-body or housing is provided in the headlamp for the sealed beam unit mounting. This sub-body is retained in the headlamp by the two adjusting screws and by two sets of two springs which are hooked to the sub-body diametrically across from each screw. The sealed beam unit seats directly in the sub-body and is positioned by three heavy lugs which fit into slots in the sub-body. A retainer ring is fitted over the outer edge of the sealed beam unit. This retainer ring has three lugs which engage three clamp screws on the sub-body rim so that the retainer ring and sealed beam unit are securely clamped in place when the clamp screws are tightened (on some cars a gasket is used between the retainer ring and the sealed beam unit). A lamp rim which fits over the retainer ring in such a manner as to conceal the clamp screws and adjusting screws completes the assembly.

Removing Sealed Beam Units—Remove headlamp rim (retained by screws and clips). Loosen but do not remove three clamp screws which engage retainer ring or remove spring (some models) which is attached to retainer ring. In first type rotate retainer ring to release retainer and in both types remove unit connector and unit.

Installing Sealed Beam Units—Terminal clips on sealed beam units and cable plug are designed so that plug can be connected only in correct position. Plug terminals (facing end of plug) are as follows: **Left Side**—Upper Country Beam. **Center (Top)**—Lower Traffic Beam. **Right Side**—Ground wire connected to lamp sub-body or lamp housing. When installing new sealed beam unit, connect plug, see that sealed beam unit lugs properly engage slots in sub-body, install retainer ring and rotate ring clockwise until lugs on ring engage under clamp screw heads on sub-body, or connect spring which secures retainer, tighten clamp screws securely. Then adjust headlamps as directed below.

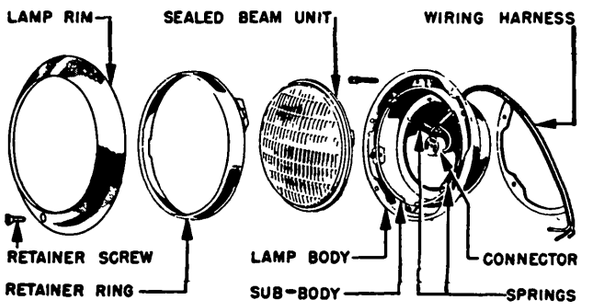
STANDARD (5000 SERIES)

AIM LOWER BEAM OF HEADLAMP

6000 SERIES (TYPE 2)

SEALED BEAM HEADLIGHT AIMING CHART

ADJUSTMENT: *CAUTION - "Standard" (5000 Series) and "Type 2" (6000 Series) units are used. "Type 2" has number 2 molded into lens at top of bulb. Different adjustment required for each type as detailed below. If both types found on a car, adjust each type according to specifications for that type.* With car perpendicular to and 25 feet from screen or wall, make a horizontal line on wall **2" below** horizontal centerline of headlights (Standard), horizontal line on wall **even with** horizontal centerline of headlights (Type 2). Make a vertical line on wall through the vertical centerline of each headlight (All Types). Cover the headlight not being adjusted. Proceed as follows:



►*NOTE:* Always bring headlight beam into final position by turning aiming screws clockwise so that unit is held under proper tension when adjustment completed.

Standard (5000 Series) Adjustment: Vertical - With headlights on HIGH BEAM, turn vertical aiming screw (at top of bulb) counterclockwise so center of high intensity area is much lower than horizontal centerline on wall. Then turn screw clockwise so center of high intensity area is in the center of horizontal line. **Horizontal** - With headlights on HIGH BEAM, turn horizontal aiming screw (at side of bulb) counterclockwise, then clockwise so center of high intensity area is in the center of vertical centerline.

Type 2 (6000 Series) Adjustment: Vertical - With headlights on LOW BEAM, turn vertical aiming screw (at top of bulb) counterclockwise so center of high intensity area is much lower than horizontal centerline on wall. Then turn screw clockwise so top edge of high intensity area is even with horizontal centerline.

Horizontal - With headlights on LOW BEAM, turn horizontal aiming screw (at side of bulb) counterclockwise, then clockwise so left edge of high intensity area is 2" to the right of vertical centerline.

►*T-3 AIMING EQUIPMENT NOTE:* Aiming equipment may be used with all types headlights. Follow manufacturer's instructions.

SEALED BEAM HEADLIGHT UNIT

SEALED BEAM HEADLAMPS (4-HEADLIGHT SYSTEMS)

►CHANGES, CAUTIONS, CORRECTIONS

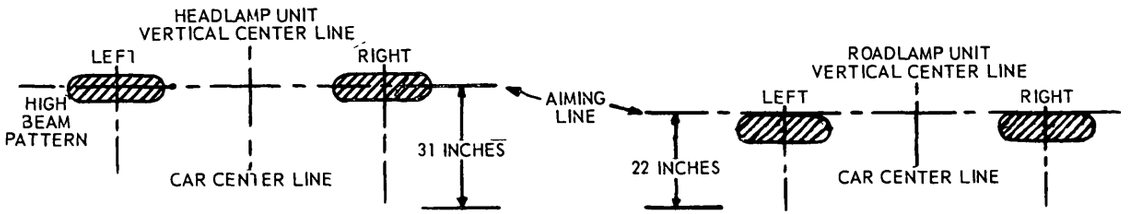
►*1957 DESOTO HEADLIGHT DOOR INTERFERENCE (First Cars):* Before installing door after aiming headlights, inspect inner side of door and see that lower slots in door flange provide clearance for ears on sealed beam mounting units. If necessary, lengthen slot (lower end of outer lamp slot, upper end of inner lamp slot) to completely clear the ears.

►*1957 LINCOLN AUXILIARY HEADLIGHT WIRING MODIFICATION:* The headlight wiring can be modified so that it will be IMPOSSIBLE to use the Headlights and Roadlamps (second set of Headlights) at the same time, wherever this is preferred or required by regulations. Proceed as follows: Disconnect lead wires on existing Auxiliary Over-ride Switch (on steering column), remove and discard switch. Install new switch, Part No. FDU-15224-C. Connect switch leads as follows: 1) Red Switch Lead with bullet terminal to Blue Lead in Wiring harness, 2) Tape Black Wire in harness (not used). 3) Route Yellow and Black Leads from switch along main wiring harness to Light Switch, 4) Disconnect Red-with-Yellow-Band Wire from Light Switch and connect new Yellow lead to this terminal, 5) Connect Black Lead to the Red-with-Yellow-Band Wire disconnected from the switch.

DESCRIPTION & OPERATION: The 4-Headlight systems use four Sealed Beam units of different size (see Lamp Bulb Data below). Conventional double filament headlights (Upper and Lower Beam) are supplemented by a second set of single filament headlights (Upper Beam only) mounted beside (toward center of car) or below the regular headlights. These additional headlights are connected directly to the upper beam lead of the regular headlights so that they are illuminated only when the upper beams are in use (except Lincoln - see Lincoln Wiring Note below). When the regular headlights are switched to lower beam the additional headlights go out, and the usual two-headlight pattern is presented to a passing car.

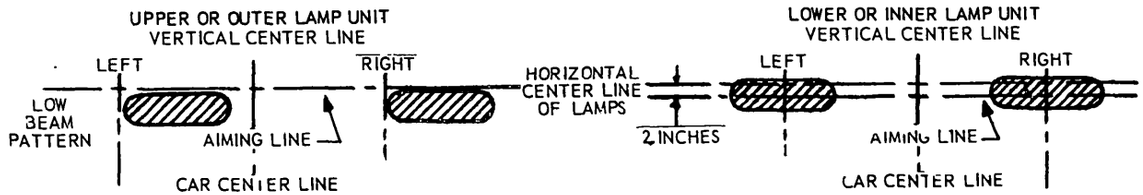
►*1957 LINCOLN HEADLIGHT WIRING NOTE:* See Wiring *Modification (above).* The Auxiliary Headlights (additional headlights) are controlled by the main Lighting Switch and are lighted with the switch in the "Park" position (Parking & Tail Lights on, regular Headlights off) and also with the switch in the regular "On" position (Regular Headlights and Tail Lights on, Parking Lights off). The Auxiliary Headlights are not controlled by the Beam Selector Switch and do not go out when the regular headlights are switched to Lower Beam. However, an Auxiliary Over-ride Switch is provided (on right side of steering column) so that the Auxiliary Headlights can be switched off whenever they are not wanted.

Lamp Bulbs (All Models except Lincoln - see Lincoln Bulb Note below): New 5¾" Special Sealed Beam Units. Regular headlight units (double filament) are three-prong type, auxiliary headlight units (single filament) are two-prong type and units cannot be installed incorrectly. **Regular Headlight (Outer or Upper Unit)** - No. 4002 (50-37½ W). Numeral "2" is molded in top of lens. **Auxiliary Headlight (Inner or Lower Unit)** - No. 4001 (37½ W). Numeral "1" is molded in top of lens.



►*1957 LINCOLN BULB NOTE:* This model does not use the new small bulb units. Regular headlights are Sealed Beam Unit, No. 5400 (50-40W); Roadlamps (second set of headlights) are Sealed Beam Unit, No. 4415 (35W-single filament).

HEADLIGHT AIMING & ADJUSTMENT: All headlights are aimed with reference to lamp "Vertical Center-line" and it will be necessary to establish separate center-lines on the screen for outer and inner headlights (side-by-side mounting, or for diagonal mounting as used on Lincoln & Continental). A "Horizontal Lamp Center-line" is also used together with the usual horizontal line 2" below lamp center-height. Correct light patterns are shown in illustration.



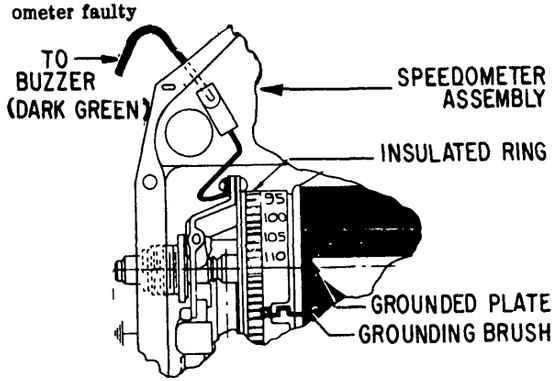
►*1958-60 CHEVROLET & 1960 CORVAIR LOW BEAM PATTERN NOTE: "Hot Spot" f patt rn should be 1" to right of outer lamp vertical c nt rlin n screen.*

Headlight Aiming Gauges - Sealed beam units have the usual pedestals or gauge points molded in the lens and T-3 or other Gauges can be used for headlight adjustment if the necessary adapters are used.

Headlight Aiming Tolerance - Tolerances are Plus or Minus 2" (vertical limits), Plus or Minus 6" (horizontal limits).

1957 LINCOLN MODELS

1957-60 MODELS (EXCEPT 1957 LINCOLN)
4-HEADLIGHT AIMING CHARTS (ALL MODELS)



1958-60 BUICK

DESCRIPTION & OPERATION: Unit consists of a buzzer mounted on left ventilator air deflector and connected to the fuse block by a dark green wire. An insulated ring with a dial reading of 20-110 is part of the speedometer assembly. A grounding brush projects from this ring to a grounded plate on speedometer cylinder. The ring is rotated by turning a knob on lower instrument panel to desired speed setting. When cylinder rotates and reaches desired speed, grounded plate will contact grounding brush causing buzzer to sound.

TESTING & TROUBLE SHOOTING: Buzzer Inoperative or Operates Intermittently - Disconnect buzzer at speedometer (slip fuse block down and reach with left hand between fuse block brackets and forward of heat duct). Ground connector with ignition switch ON. If buzzer operates, speedometer is faulty. If buzzer does not operate, fuse is blown, connectors loose, or buzzer faulty.

Buzzer Operates Continuously - Disconnect wire at speedometer. If buzzer stops speedometer is faulty. If buzzer does not stop, buzzer is faulty. Green wire from speedometer to buzzer may be grounded.

Speedometer Sticks - Buzzer must be resistor type (identified by pig tail welded to mounting base). Speedometer faulty

1958 EDSEL

►*WARNING LIGHTS REMAIN ON CORRECTION:* Transfer red feed wire from 12 amp. circuit breaker on fuse panel to "ACC" terminal of ignition switch. *See Car Wiring Diagram for recommended wiring.*

DESCRIPTION & OPERATION: Unit consists of two warning lamps, a control assembly, and a selector control knob and cable. Any speed from 20 to 80 MPH can be selected by turning knob (located just below speedometer). Two flyweights are mounted on a shaft turned by speedometer cable. As speed of flyweights increases, weights move outward, shortening length of flyweight scissors and moving a lever against spring tension (determined by selector knob). This closes a set of points and causes the lamps to light, producing a red glow on speedometer dial.

1958 MERCURY

DESCRIPTION & OPERATION: Unit consists of a selector knob and dial, electrically operated chimes signal, set of contact points in speedometer which ground chimes circuit. Any speed in 5 mile increments between 20-110 MPH may be selected. Tension of a speedometer driven spool spring is controlled by setting of selector dial. When desired speed is reached, points close, completing the circuit and chimes will ring intermittently.

►*SERVICE NOTE:* All service of unit is by replacement

Chimes Assembly Removal & Installation: Disconnect battery ground cable at battery. Disconnect wires at chimes assembly noting carefully position of wires. Remove bolt securing chimes to brake pedal support and remove assembly. Reverse procedure to install.

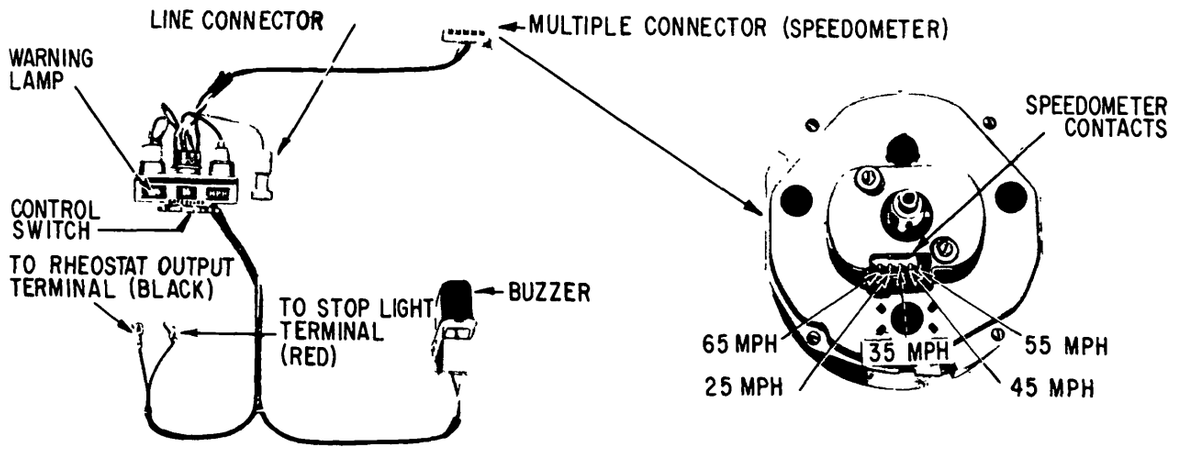
Selector Dial & Speedometer Synchronization: Raise rear of car so wheels turn freely. Set selector knob on maximum speed position. Start engine and place transmission in gear to obtain constant speedometer reading of 40 MPH. *NOTE - This speed may be varied according to driver's preference.* Rotate knob until chimes sound. Hold knob and rotate dial until number 40 indexed with red mark on bezel.

1959 MERCURY

DESCRIPTION & OPERATION: Consists of a control knob on left side of speedometer hood, spiral grooved shaft with an indicator pointer linked to knob by a bead chain, a black tape wound on a spring-loaded spool behind speedometer tape, and a warning light. Unit operative at any speed between 25 and 90 MPH. Control knob causes indicator pointer to move on speedometer face to desired speed. Indicator pointer pulls black tape behind speedometer tape at same time. When desired speed is reached and exceeded, red part of speedometer tape that passes over pointer lights up (warning bulb is located behind it). *NOTE* - Warning light does not glow until road speed slightly exceeds indicator setting.

►*SERVICE NOTE: All service of unit is by replacement.*

Warning Lamp Replacement - Disconnect battery ground cable. Remove screws holding hood and speedometer assembly to instrument cluster. Raise assembly up and off dowel pins. Warning lamp located at center of speedometer just below high beam indicator lamp.



1958 PONTIAC

DESCRIPTION & OPERATION: Unit consists of a control switch on instrument panel allowing 5 settings from 25 to 65 MPH in 10 mile increments, and a warning buzzer and light. Speedometer is equipped to make contact with any one of the five contact points. When desired speed is reached circuit is completed and buzzer and light will operate over a 9 mile range above pre-set speed. Then they stop until car speed is reduced within the range.

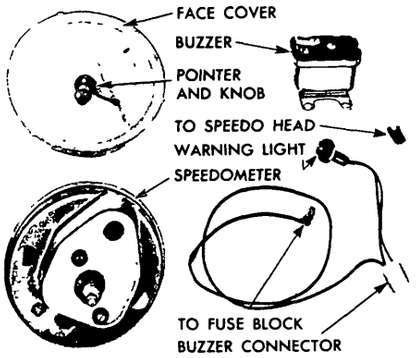
TESTING & TROUBLE SHOOTING: 1) If both buzzer and lamp fail, check stop lamp fuse. If only buzzer works, replace bulb. Ground circuit at line connector. If both buzzer and lamp fail, both are faulty; if they operate, switch, multiple connector, or speedometer are faulty.

2) Check all five multiple connector contacts. If buzzer and lamp do not operate, switch or line connector, or speedometer are faulty.

3) If only one or more speed positions are inoperative, contacts are not grounding. To check, place a jumper wire between line connector and individual contacts.

1958-59 OLDSMOBILE

DESCRIPTION & OPERATION: Unit consists of a buzzer behind instrument panel and a light below odometer, a selector knob and dial, and a hair spring on speedometer hand shaft. Any speed from 12 MPH may be selected. *CAUTION - Do not set below 12 MPH.* A hand is mounted behind speedometer and, when speedometer hand reaches Safety Sentinal hand, contact with an insulated pin is made, completing circuit and causing buzzer to sound and light to go on.



TESTING: Make sure the fuse (yellow wire) is not blown. *NOTE - Parking brake lamp, safety switch, backup lamps, temperature, generator, oil pressure warning lamps and fuel gauge are also on this fuse.* Raise rear wheels from floor. Adjust selector knob to 30 MPH. Accelerate to 32 MPH. Buzzer and light should operate. If buzzer sounds and light is out, bulb is faulty. If light is on and buzzer does not sound, remove yellow wire from instrument cluster and ground with ignition switch in "ACC" position. If buzzer still silent, replace it. If buzzer and light does not operate but other units in same circuit do, and connection to printed circuit is good, speedometer is faulty.

1959-60 PONTIAC

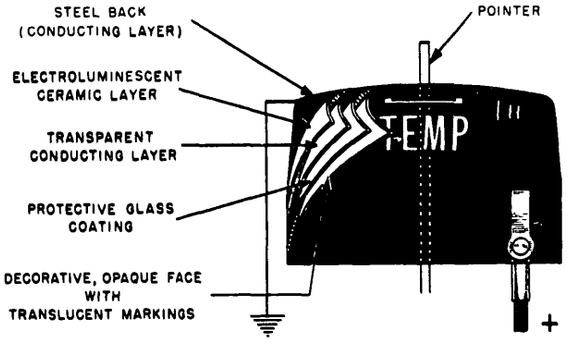
DESCRIPTION & OPERATION: Consists of a setting knob in center of speedometer lens which is connected to a shaft through lens (shaft has a stop to prevent settings below 15 MPH). A speed warning pointer is connected to shaft and pointer moves with shaft to desired setting. Speedometer pointer has a silver alloy contact which contacts speed warning pointer when desired speed is reached so circuit is completed and buzzer and warning light are actuated until speed is reduced below setting.

►*INSUFFICIENT BUZZER LOUDNESS CORRECTION (Early Cars):* Relocate buzzer to left hand defroster nozzle over wiring clip. Reverse clip to accommodate buzzer and, on air conditioned cars, insulate buzzer terminals and center rivet to prevent a short circuit with air conditioning duct.

TESTING: If both buzzer and lamp inoperative, check speedometer fuse. If buzzer only operates, replace lamp bulb. Check circuit at line connector. If buzzer and lamp inoperative at all pointer positions, contacts or line connector are at fault. If buzzer and lamp operate at all speeds, speedometer or line connector are at fault.

PONTIAC SPEED WARNING ASSEMBLY

CHRYSLER PANELESCENT INSTRUMENT LIGHTING



Chrysler & Imperial Models (1960)

►*PANELESCENT LIGHTING SERVICE CAUTION:* System operates at 200 volts, 250 cycles, A.C.; and In strument Panel Switch must be turned off BEFORE disconnecting leads or connecting test equipment to prevent possibility of electric shock from the high voltage. Terminals are protected and shock should not occur unless they are disconnected with the current on. *NOTE* – Wattage of system is low and shock should not result in injury.

DESCRIPTION: Panelescent lighting does not employ conventional bulbs or lamps filaments. Each instrument or other illuminated device has a dial face built up of layers which include an electroluminescent (phosphorescent) layer which glows when the high voltage is applied to the transparent conducting layer (see illustration). Instrument pointers are similarly constructed and also serve as light sources. Power for the system is provided by a Power Pack or Oscillator which converts the 12 volt D.C. power supply to 200 volt, 250 cycle A.C. Power Pack cannot be repaired and is serviced by replacement.

TROUBLE SHOOTING & DIAGNOSIS: *See Service Caution above.* A failure of the power supply or a short-circuit at any of the panel units will cause the entire panel to remain unlighted. An open-circuit at any one of the panel units will cause that unit only to remain unlighted and all other units will be lighted normally. Check by turning on instrument panel switch and observe lighting.

One or More Instruments Unlighted: Replace unit and recheck lighting.

TYPICAL PANELESCENT GAUGE

Entire Panel Unlighted: Turn instrument light switch OFF. Connect tester, Tool C–3764, at Power Pack (disconnect Power Pack connectors, plug in one tool connector to Power Pack, other tool connector to line connector, connect tester BLACK wire to a good ground on the instrument panel). Turn on instrument light switch and observe indicators on ends of tester. Both indicators should glow. *NOTE – Indicator at BLACK end is low voltage D.C. indicator. Indicator at RED end is high voltage A.C. indicator.* If both indicators do not glow, proceed as follows:

Neither Indicator Glows – Supply circuit (orange wire) is open. Check this wire and instrument panel light switch.

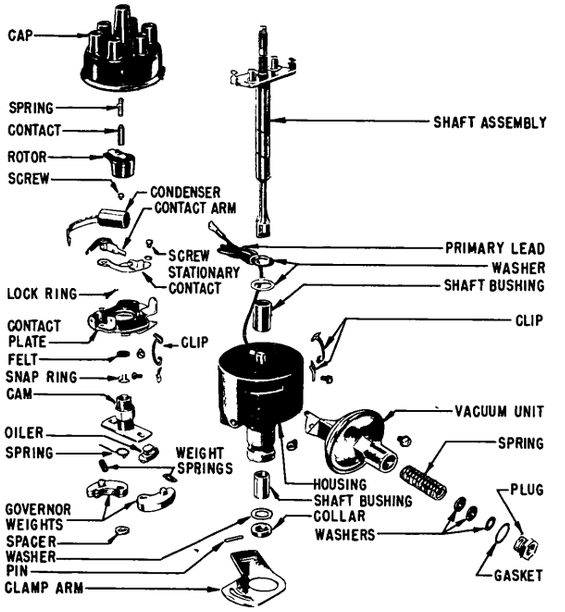
Black (D.C.) Indicator Glows – Red (A.C.) Indicator does not Glow – Power Pack is not operating. Replace unit and recheck system.

Both Indicators Glow – This indicates that one or more of the instruments are short-circuited. Disconnect each unit in succession and check by touching test prod (white wire) of tester to the instrument terminal. If instrument does not light up, it is short-circuited and must be replaced. *CAUTION – If more than one instrument is shorted, panel will remain dark after the first instrument is replaced. Continue to check all oth r instruments.*

AUTOLITE DISTRIBUTORS (SINGLE & DOUBLE BREAKER TYPE)

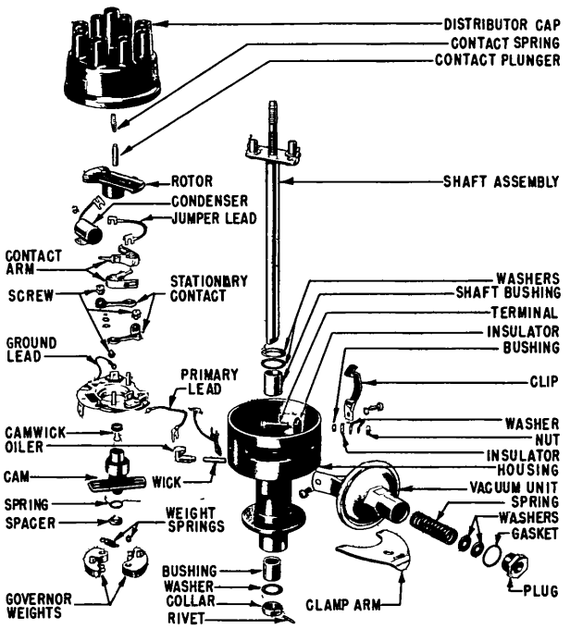
DESCRIPTION: **Single breaker distributors** have a pivoted type breaker plate assembly consisting of a support plate which is mounted rigidly in housing and a separate breaker plate on which the contact assembly and condenser are mounted. The breaker plate is pivoted on support plate at a point under the condenser and rests on brass supports on plate. A tension spring on underside of support plate provides constant uniform friction between the two plates and governs action of vacuum unit in rotating the plate to advance or retard the spark.

Dubl br ak r distributors have a ball bearing type breaker plate assembly which consists of a support plate mounted in distributor housing and a breaker plate on which the contact assemblies and condenser are mounted. Retainer clips on support plate engage the bearing assembly on underside of breaker plate and hold the assembly firmly in recess in support plate. **On all distributors** the vacuum advance link connects directly to breaker plate and rotates it around distributor cam. A single spring is used on each governor advance weight. One spring has light tension to control low speed advance. Other spring has heavy tension for high speed control.



ADJUSTMENT: **Aut matic Advance** - With distributor installed in testing equipment, check distributor automatic advance. *See Car Model pages for "Automatic Advance Specifications".* To adjust automatic advance, bend outer spring lug of light spring for low speed and outer lug of heavy spring for high speed operation.

Vacuum Advanc : *NOTE - Vacuum advance units on 6 Cyl. distributors cannot be adjusted. Replace vacuum unit if not within specifications.* Check vacuum advance after checking automatic advance (above). *See Car Model pages for "Vacuum Advance Specifications".* To adjust V8 vacuum advance unit, adjust washers as follows: Remove retaining plug and gasket and remove washers. Check thickness of removed washers and substitute thinner washer if vacuum required to move plate is greater than specified. Substitute thicker washer if vacuum required to move plate is less than specified. *NOTE - In some cases it may be n cessary to replace spring, then adjust to specifications by means of various combinations of washers.*



C ntact P int Alignm nt & Gap Setting: Align contacts to provide center contact by bending stationary contact only. Grip bracket next to contact and bend it away from breaker arm, then bend it back to vertical. *NOTE - A new contact is always lower than breaker arm.* If necessary, repeat bending process several times to obtain perfect alignment. *CAUTION - Do not bend movable breaker arm.* After points aligned, check point gap with dial indicator *(see Car Model pages for specifications).*

Br aker Arm Spring Tension: *See Car Model pages for specifications.* Measure tension at point surfaces with a spring scale at right angle to point surfaces. Note scale reading at point where contacts start to separate. To adjust, move end of point spring in or out as necessary.

DISASSEMBLY: Remove vacuum unit, distributor cap clamp springs, and rotor. On single breaker distributors, push in rubber grommet and remove primary lead. On

SINGLE BREAKER DISTRIBUTOR (TYPICAL)

DOUBLE BREAKER DISTRIBUTOR (TYPICAL)

double breaker distributors, loosen primary terminal post nut and remove primary lead. Remove breaker plate attaching screws and remove breaker plate assembly. Remove cam felt and spring clip retainer from center of cam and remove anti-rattle spring. *Check distributor shaft sideplay (see below).* Remove cam and yoke. Drive retaining pin from drive collar and shaft and remove collar. Remove lower thrust washer and push shaft out through top of housing. *NOTE - On distributors with driven gear held on shaft with retaining pin, support hub of gear so gear not damaged when pin driven out.* Remove upper thrust washers, oiler and oiler wick. Remove governor weights and springs.

Inspection: Wash all parts except breaker plate and vacuum diaphragm in solvent and blow dry with air. Check operation of governor weights and check weight springs for distortion. Inspect all bearing surfaces and pivot points for binding, roughness or excessive wear.

Drive Shaft Sideplay: With distributor clamped in a vise, attach a dial indicator to body with indicator plunger against cam. Move shaft back and forth with just enough force to indicate clearance. If sideplay exceeds .005", replace bushings or shaft (see below).

Drive Shaft Endplay: .003-.010" measured after drive shaft collar riveted in place.

Bushing Replacement: On 6 Cyl. distributors, remove bushings with a suitable tap and puller (C-3744). DO NOT drive bushings from housing. On V8 distributors, drive bushings from housing with a suitable driver (C-3041). On all distributors, install new bushings with suitable adapter and driver (C-3041) and press new upper bushing into position in bore. *NOTE - Soak bushing in light engin oil for 15 minutes before installation.* When properly installed, the bushing will be .094" below top of bore. Invert distributor housing and press lower bushing in until it is flush with bottom face of distributor. Drill a 1/8" hole through upper bushing by drilling through oil wick hole. Remove burrs from hole after drilling. Install suitable burnishing tool (part of C-3041) and force through both bushings. Burnishing tool should finish inside diameter to .4995-.5000". Maximum bushing-to-shaft clearance .0005".

REASSEMBLY: Place grease in lubricant hole of governor weights and install weights and springs. Install anti-rattle spring. Slide cam and yoke over end of drive shaft and secure with spring clip. As cam and yoke are being slid over shaft, engage weight lugs with slots in yoke. Lubricate governor weight pivots, yoke slots and cam sleeve with engine oil. Slide inner thrust washers over shaft and up into position against governor plate. Lubricate shaft with light engine oil and install in distributor. Slide outer thrust washer and collar over drive shaft, then install a new pin and peen ends of pin over shaft. *NOTE - On distributors with driven gear held on shaft with retainer pin, support hub of gear so gear will not be damaged when pin driven in.* Soak oiler wick and felt pad in light engine oil, squeeze slightly, then install. Install oiler by tapping into place. Install breaker plate assembly into position and line up attaching screw holes, then attach distributor cap clamp springs and screws and tighten securely. On single breaker distributors, slide primary lead through hole in body and seat grommet in hole. On double breaker distributors, install terminal post assembly. Install vacuum unit, engaging vacuum unit arm with pin on breaker plate. Install attaching screws and tighten securely. Install spring clip over breaker plate pin to secure vacuum unit arm. Install condenser, stationary contact arm, and breaker arm.

CHRYSLER CORP. DISTRIBUTORS

Chrysler (1961)
Dodge & Plymouth (1960-61)
Lancer (1961)
Valiant (1960-61)

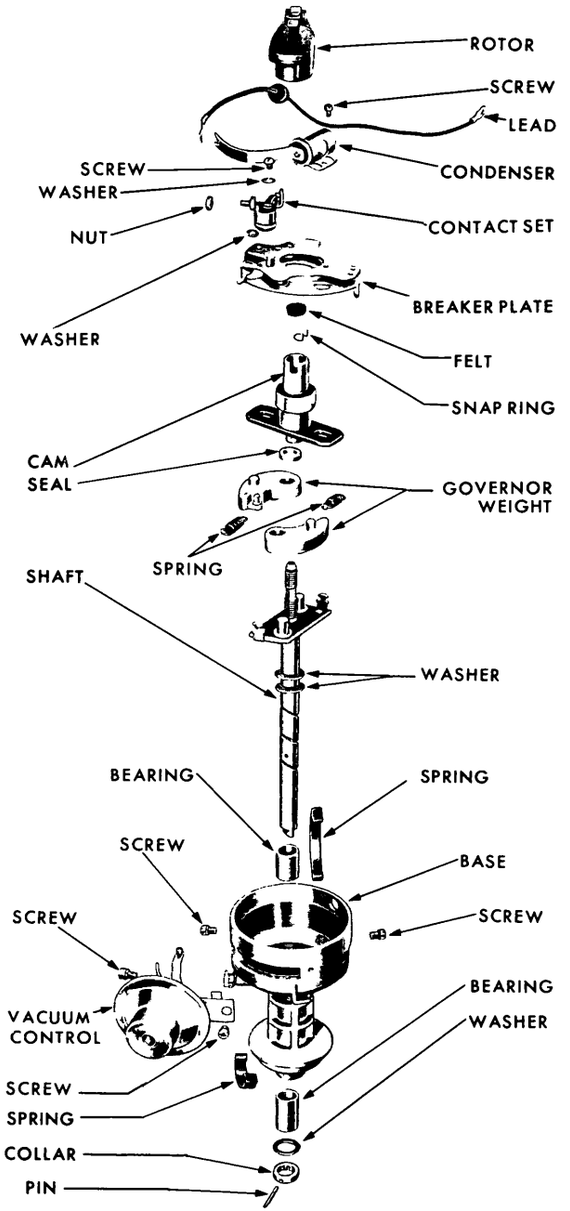
DESCRIPTION: Single breaker type distributor with a "pivoted" type breaker plate. The breaker plate assembly consists of a support plate which is attached rigidly to distributor housing and a movable breaker plate which is pivoted on support plate at a point under the condenser. Distributor primary lead is a continuous wire which enters housing through an insulating grommet.

DISASSEMBLY: Remove rotor, then remove clip attaching vacuum control unit to breaker advance arm and remove vacuum control unit from distributor housing. Remove primary lead terminal at terminal screw and remove primary lead wire and grommet as an assembly from distributor housing. Remove two screws and lockwashers attaching breaker plate assembly to housing and lift out the complete assembly including points and condenser. Remove oil wick from distributor cam, then remove wire clip from well in cam and remove cam, yoke and spacer. Clamp distributor in a vise (with soft jaws) and attach a dial indicator to body of distributor with indicator plunger resting against distributor shaft. Hook a spring scale over shaft and pull on a line with plunger of gauge. Apply a 5 lb. pull and check movement of distributor shaft. If side play exceeds .005", replace bushings and shaft. Remove distributor drive gear (six cylinder) or collar (V8) retaining pin and slide gear or collar off shaft. *NOTE - Support hub of gear or collar so pin can be driven out without damaging parts.* Clean burrs from around pin hole and remove lower thrust washer. Push shaft up and remove through top of distributor, then remove upper thrust washers, shaft oiler and oiler wick.

BUSHING REPLACEMENT: Remove upper and lower bushings with Tool C-3744. *CAUTION - Do not drive bushings out of housing.* Before installing new bushings, soak in light engine oil for approximately 15 minutes. Position upper bushing with slot in bushing up and in line with oil hole in housing. Press bushing into housing with Tool C-3041 and adaptor (flat face of adaptor contacting bushing). When properly installed, upper end of bushing should be 1.613" from top of distributor housing (measured from bottom edge of straightedge to top of bushing. Invert distributor and install lower bushing flush with face of distributor base. *NOTE* - Insert a 3/32" rod through housing oiler hole to see if slot in bushing indexes with oiler hole in housing. If rod cannot be inserted through housing and bushing, drill a 1/8" hole through upper bushing by drilling through oil wick hole (remove burrs caused by drilling). Install burnishing tool, C-3041 and press burnisher through both bushings.

REASSEMBLY: Check operation of centrifugal weight and check weight springs for distortion. Lubricate governor weights and inspect all bearing surfaces and pivot pins for roughness, binding or excessive looseness. Install spacer on distributor shaft, then slide cam and yoke assembly on distributor shaft and engage weight lugs with slots in yoke. Install cam retaining spring clip, then lubricate and install upper thrust washers on shaft and slide shaft into distributor body. Position lower thrust washer and drive gear on lower end of shaft and install roll pin. *NOTE - Support hub of gear when installing pin so gear will not be damaged.* Install oiler wick and oiler, then install breaker plate assembly. Align condenser lead, breaker point spring, and primary lead, install attaching screws. Install felt wick in top of distributor cam. Attach vacuum control unit to breaker plate and install retainer clip and washer, then install vacuum unit attaching screws. Check breaker arm spring tension (see below) and adjust point gap. Lubricate felt pad in top of distributor cam with 3 to 5 drops of light engine oil and install rotor.

PERFORMANCE DATA: *See Car Model pages for Automatic & Vacuum Advance specifications.*



►*DISTRIBUTOR POINT GAP & DWELL NOTE:* Point gap and dwell must be within specifications at the same time (see Car Model pages for data). If this cannot be accomplished, either wrong points are installed or cam lobes are badly worn. Check dwell with engine idling at 475-500 RPM. *Dwell variation at speeds above 1500 RPM is not an indication of distributor wear.*

BREAKER ARM SPRING TENSION: Hook spring scale, Tool MTU-36 on breaker arm and pull in a straight line at a right angle to point surfaces. Take a reading as points start to separate. Spring tension should be 17-21.5 ozs. If not within limits, loosen screw holding end of point spring and slide end of spring in or out as necessary. Tighten screw and recheck spring tension.

LUBRICATION: Add 3 to 5 drops of SAE 10W oil to oiler on outside of distributor base and to felt wick under rotor in top of distributor cam. Wipe old grease from surface of breaker cam and apply a light film of new distributor cam grease. *CAUTION - Do not over-lubricate.*

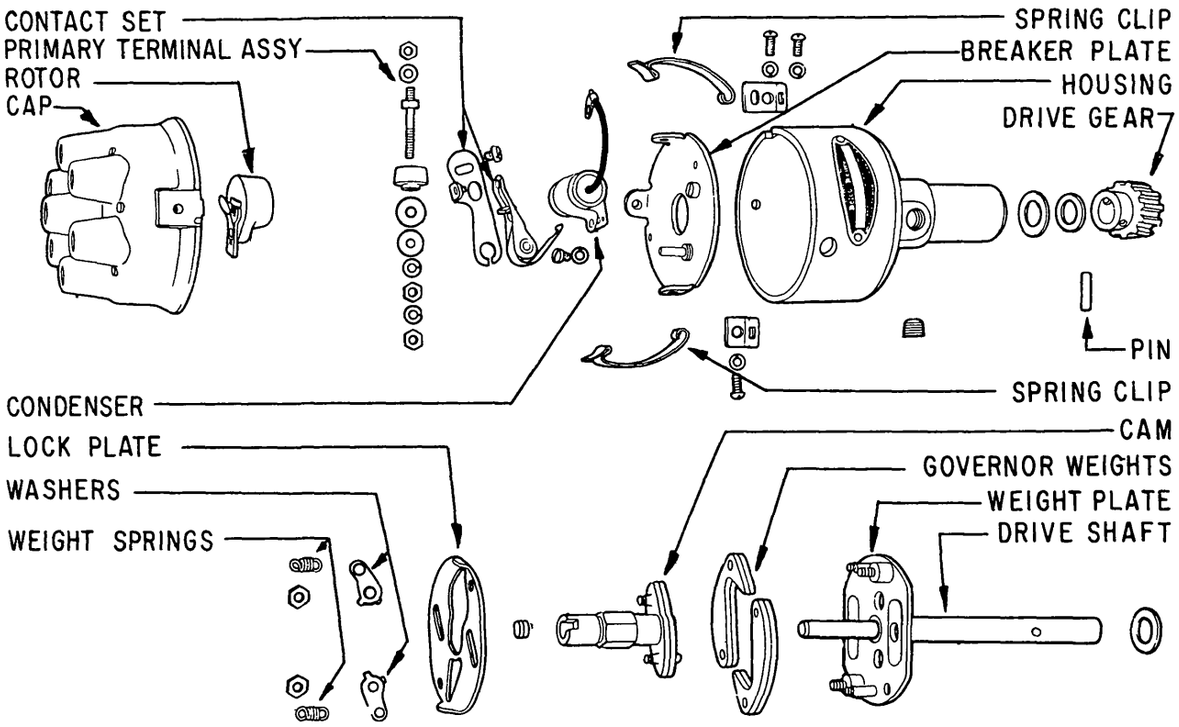
VACUUM CONTROL UNIT: This unit cannot be disassembled or adjusted. If not within specifications, replace complete vacuum control unit.

HIGH TENSION CABLES: These cables have a non-metallic string type conductor for improved radio noise suppression. Do not jerk cables off spark plugs or out of distributor cap towers as cables may pull out of terminals or be damaged. Check cables for excessive resistance or open circuit. Replace cable if resistance is greater than 30,000 ohms or if terminal has pulled off.

CHRYSLER CORP. DISTRIBUTOR ASSY. (V8 SHOWN - 6 CYL. SIMILAR)

DELCO-REMY "FIXED PLATE" DISTRIBUTORS

DESCRIPTION: Single breaker, fully automatic type Centrifugal advance consists of an automatic cam actuated by two centrifugal weights controlled by springs and mounted under breaker plate Breaker plate is rigidly mounted in distributor housing Vacuum advance is controlled by a vacuum diaphragm unit mounted below distributor housing Vacuum link is riveted to vacuum diaphragm at one end and clamped around distributor stem at other end When vacuum unit is in operation, the entire distributor is rotated in its mounting to secure the proper vacuum advance Distributors with double breakers have both contact assemblies mounted on breaker plate and linked to each other by jumper wire



ADJUSTMENT: Automatic Advance - With distributor installed in testing equipment, check distributor automatic advance *See Car Model pages for "Automatic Advance Specifications"* To adjust automatic advance, adjust weight spring calibration, or replace weights, springs, or cam

Vacuum Advanc : Check vacuum advance after checking automatic advance (above) *See Car Model pages for "Vacuum Advance Specifications"* If not within specifications, replace vacuum unit

C ntact P int S tting & Alignment: *Check contact point opening with dial indicator only* With breaker arm rubbing block on extreme top of a cam lobe which will give widest point opening, loosen support lock screw and turn adjusting screw to obtain proper gap *See Car Mod l pages for specifications* Tighten lockscrew Align points by bending fixed contact support DO NOT bend breaker lever Recheck point opening after alignment

Br aker Arm Spring Tensi n: 17-21 ozs measured at center of contact, 19-23 ozs measured just behind contact Measure tension with a suitable spring scale hooked at right angle to contact surfaces and take reading at point where contacts start to separate To adjust, bend spring carefully

DISASSEMBLY: If vacuum unit removed with distributor, loosen clamp screw and remove vacuum unit Remove rotor, breaker arm (loosen insulated terminal outside spanner nut), contact point and support assembly, and condenser Remove insulated terminal stud assembly Remove breaker plate attaching screws and remove breaker plate Remove lubrication cup, spring and bakelite shaft contact plug *NOTE - On distributors with tachometer drive, remove thrust plug and accessory drive shaft from housing before distributor drive shaft can be removed* Drive out pin holding drive gear to shaft, remove gear and lift out shaft and advance mechanism Bend lock plate tangs and remove nuts, lock plate and hold down plate Remove governor weights, springs, and cam from shaft

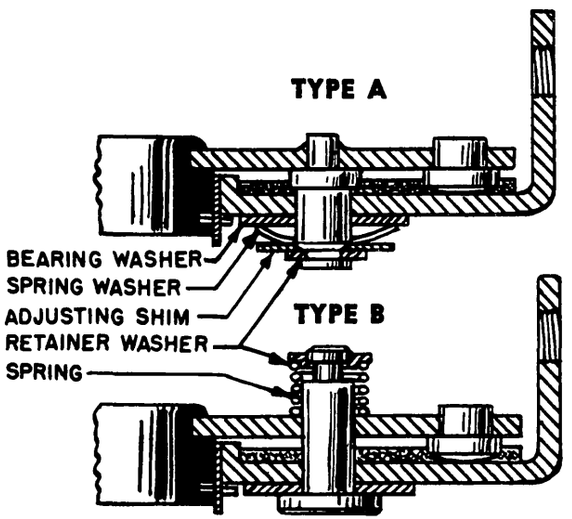
DELCO-REMY "FIXED PLATE" DISTRIBUTOR (EXPLODED)

Inspection: Wash all parts except cap, rotor, condenser, and vacuum unit in solvent and blow dry with air Inspect all parts for wear, roughness, and for free operation If shaft or bearings are worn, replace shaft and housing *NOTE - If bushings are replaced, use a special arbor and extreme care so that bearing surface is not damaged during installation DO NOT ream new bushings* Check alignment of shaft Shaft runout should not exceed 002"

REASSEMBLY: Assemble governor weights on shaft Oil top of shaft, install cam and weight springs Install hold down plate, lock plate, and nuts and bend lock plate tangs up Lubricate shaft and install in housing Install drive gear with new retainer pin *NOTE - When installing tachometer drive gear and shaft, add or remov shims at thrust plug to obtain 005-010" endplay of accessory drive shaft Pack accessory drive chamber with Delco-Remy No 2½ grease* Install breaker plate assembly Install primary terminal assembly loosely Install condenser and contact point assembly and tighten primary terminal stud Fill lubrication cup with chassis lubricant and install bakelite plug, spring and cup Install vacuum unit Check for free operation of all components

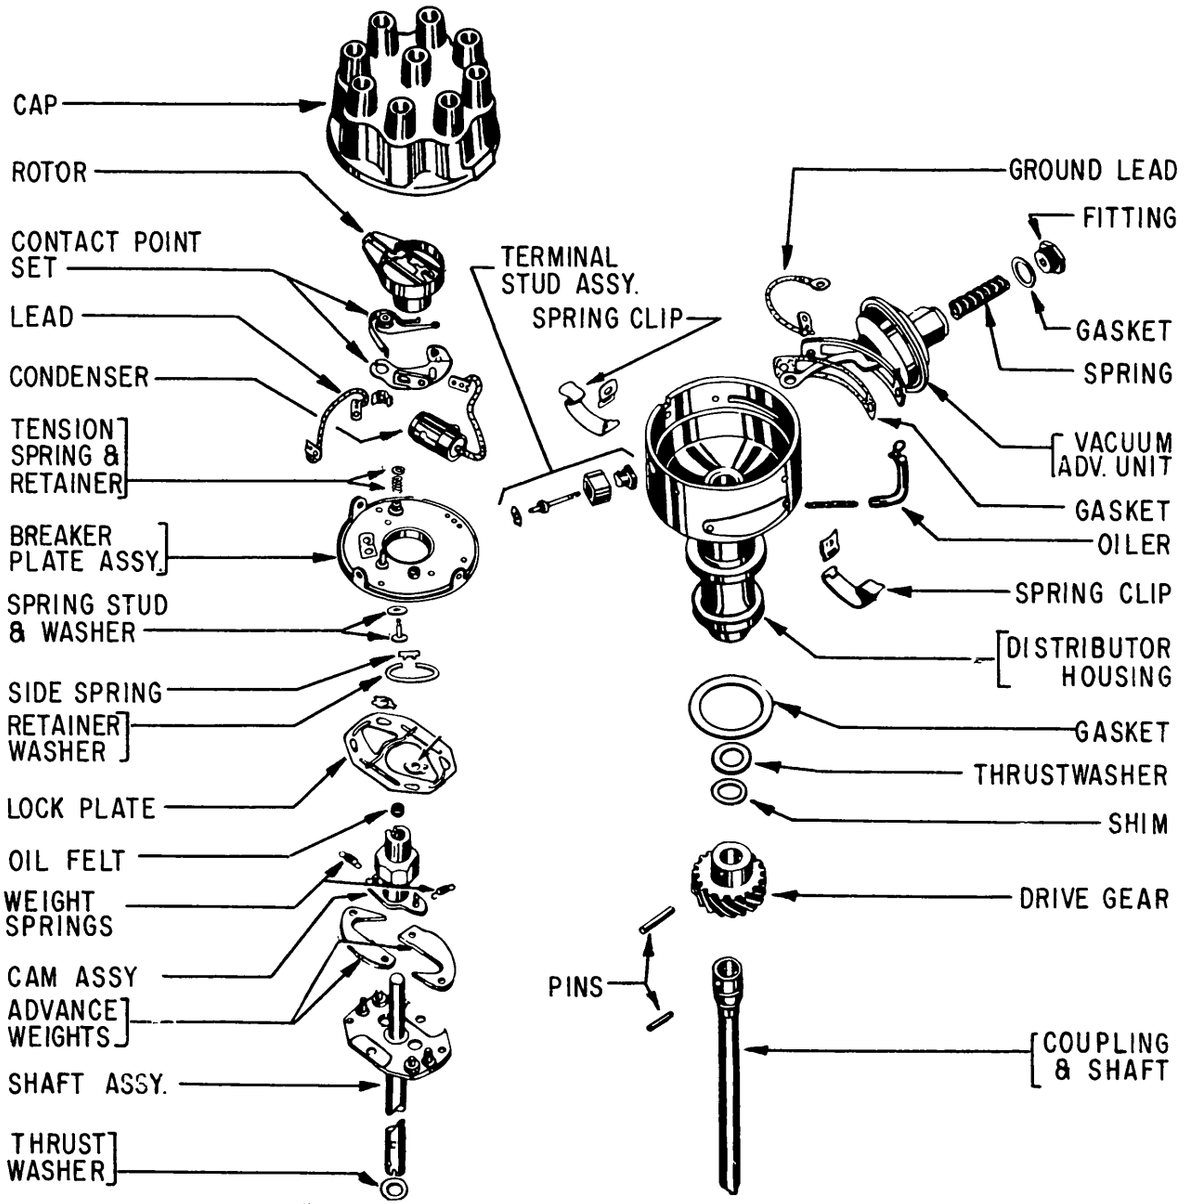
DELCO-REMY "CENTER-BEARING BREAKER PLATE" DISTRIBUTOR

DESCRIPTION: Single breaker, fully automatic with centrifugal and vacuum advance. "Center Bearing" breaker plate assembly consists of a support plate rigidly mounted in distributor housing and a separate breaker plate on which contact assembly and condenser are mounted. Breaker plate rests on three bakelite buttons which slide on support plate when breaker plate is rotated by vacuum control. An oil soaked felt between support plate and breaker plate provides lubrication for buttons. Plates are held together as follows:



Type A - A breaker plate post extends down through a slot in support plate with washers and tension adjusting shims on post below support plate. A side spring in inner rim of support plate prevents tipping of breaker plate during operation.

Type B - A breaker plate post extends up through both plates and has a spiral tension spring on top of breaker plate. Spiral spring held in place by "C" washer on post. A side spring in inner rim of support plate prevents tipping of breaker plate during operation.



ADJUSTMENT: Automatic Advance - With distributor installed in testing equipment, check distributor automatic advance. *See Car Model pages for "Automatic Advance Specifications".* To adjust automatic advance, adjust weight spring calibration, or replace weights, springs, or cam.

Vacuum Advance: Check vacuum advance after checking automatic advance (above). *See Car Model pages for "Vacuum Advance Specifications".* If not within specifications, replace vacuum unit.

C ntact Point Setting & Alignment: *Check contact point opening with dial indicator only.* With breaker arm rubbing block on extreme top of a cam lobe which will give widest point opening, loosen support lock screw and turn adjusting screw to obtain proper gap. *See Car Model pages for specifications.* Tighten lockscrew. Align points by bending fixed contact support. DO NOT bend breaker lever. Recheck point opening after alignment.

BREAKER PLATE SPRING POST ASSEMBLY (TYPES A & B)

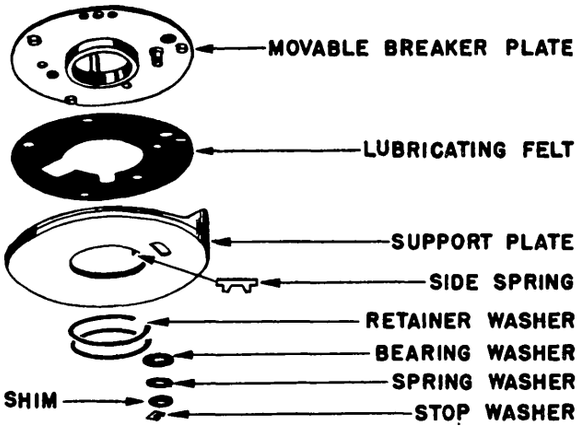
DELCO-REMY "CENTER BEARING BREAKER PLATE" DISTRIBUTOR (EXPLODED)

Breaker Arm Spring Tension: 17-21 ozs. measured at center of contact; 19-23 ozs. measured just behind contact. Measure tension with a suitable spring scale hooked at right angle to contact surfaces and take reading at point where contacts start to separate. To adjust, bend spring carefully.

Breaker Plate Tension: *NOTE - Breaker plate must have sufficient tension on support plate to prevent tipping or side movement but friction between plates must not be excessive or correct operation of vacuum control will be affected. Wh never distributor being serviced or breaker plate reassembled, check and adjust tension as follows:* With breaker plate assembly removed from distributor, hold assembly right side up and on a hori-

CONTINUED ON NEXT PAGE

DELCO-REMY "CENTER-BEARING BREAKER PLATE" DISTRIBUTOR (C ntinued)



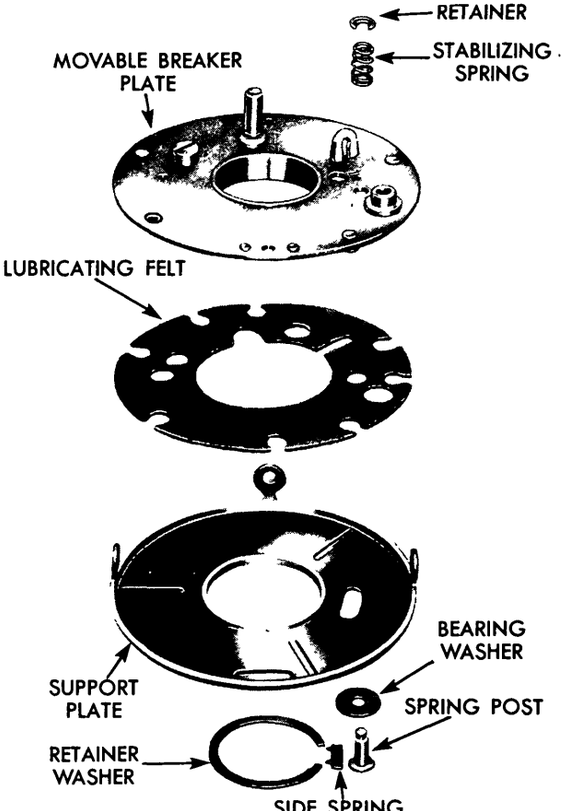
zontal plane. Hook a spring scale at stabilizer spring post and pull upward. Force required to start vertical movement of post should be 32-56 ozs. (Type A). 18-24 ozs. (Type B). With spring scale hooked to vacuum unit link connector post, maximum force required to start breaker plate rotation on support plate should be 20 ozs. (Type A), 15 ozs. (TypeB). *CAUTION - Hold spring scale directly perp ndicular to breaker plate for vertical check and dir ctly parall l for rotation check.* To adjust tension, vary the number of shim washers (Type A), stretch or replace spiral spring (Type B).

Distributor Shaft Endplay: With upper (weight plate) thrust washers between plate and housing and with shaft and plate in housing, place a shim between lower thrust washer and drive gear. Endplay should be .002-.007". Adjust endplay by adding or removing shims at drive gear end of shaft. Shims furnished .005" and .010" thick.

LUBRICATION: In addition to normal distributor lubrication, apply 3-4 drops of light engine oil through oil hole in breaker plate to felt separator at 5000 mile intervals.

DISASSEMBLY: Distributor - Remove rotor and breaker plate ground lead. Remove vacuum control unit. Remove insulated primary terminal assembly and cap clamp springs. Remove breaker plate assembly. Remove lock plate (bend retaining lugs down), weight springs, cam, and weights. *Check distributor shaft endplay (see above).* Drive the drive gear retaining pin from shaft and gear and remove gear. *NOTE - On distributors with tachometer drive, remove thrust plug and accessory drive shaft from housing before distributor drive shaft can b removed.* Remove drive shaft from housing.

Breaker Plat : *CAUTION - DO NOT disassemble Type B breaker plate with plate installed in housing, or post will drop down into housing.* Remove contact point assembly and condenser. Remove "C" washer from post, remove shims, washers and retainer washer (Type A),



DELCO-REMY "CENTER BEARING" BREAKER PLATE ASSEMBLY (TYPE A)

remove "C" washer and spiral spring from post (Type B). Separate plates. *CAUTION - Do not lose side spring in support plate.*

INSPECTION: Wash all parts except cap, rotor, condenser, and vacuum unit in solvent and blow dry with air. Inspect all parts for wear, roughness, and for free operation. If shaft or bearings are worn, replace shaft and housing. *NOTE - If bushings are replaced, use a special arbor and extreme care so that bearing surface is not damaged during installation. DO NOT ream new bushings.* Check alignment of shaft. Shaft runout should not exceed .002".

REASSEMBLY: Distributor - Reverse disassembly procedure and note the following: Oil drive shaft with light engine oil before installation. Place a few drops of oil on cam wick (if equipped). When installing tachometer drive gear and shaft, add or remove shims at thrust plug to obtain .005-.010" endplay of accessory drive shaft. Pack accessory drive chamber with Delco-Remy No. 2½ grease.

DELCO-REMY "CENTER BEARING" BREAKER PLATE ASSEMBLY (TYPE B)

Breaker Plate: Place a few drops of oil on felt separator. Reverse disassembly procedure, installing all parts in exact order (see illustrations). Check breaker plate tension (see above).

DELCO-REMY "WINDOW" DISTRIBUTORS

DESCRIPTION: The Delco-Remy "External Adjustment" (Window) Distributor has the distributor cap forming the housing enclosing all of the mechanism. Adjustments on the car are made through a slot in the side of the cap after the window has been raised and it is not necessary to remove the cap in service. *See Corvair Note b low for xception.* The contact point assembly has been designed to make this type of adjustment possible through the use of a horizontal spring-loaded adjusting screw accessible through the window slot. The entire automatic (centrifugal) advance mechanism is located above the breaker cam and is enclosed within the large circular rotor. *See illustration for design d tails.*

►*CORVAIR DISTRIBUTOR NOTE: This distributor is ss ntially the sam as conv ntional "window" distributors xc pt that no xt rnal adjustm nt is provid d for br aker gap and cam angl . This adjustment must be mad with distributor cap r mov d, contact support lock screw loosened, and a screwdriver inserted in adjusting slot in breaker plate. Cam angle for this distributor is 33° (limits 31-36°). Other overhaul differences will be pointed out in following data.*

SPECIFICATIONS: Breaker Gap - .016".
Cam Angle - 30° (28-32°).
Breaker Arm Spring Tension - 19-23 ozs.
Automatic & Vacuum Advance - *See individual car model pages.*

ADJUSTMENT: Automatic Advance - With distributor installed in testing equipment, check distributor automatic advance. *See Car Model pages for "Automatic Advance Specifications".* To adjust automatic advance, adjust weight spring calibration, or replace weights, springs, or cam.

Vacuum Advanc : Check vacuum advance after checking automatic advance (above). *S Car Mod l pag s for "Vacuum Advanc Specificati ns".* If not within specifications, replace vacuum unit.

►*CAM ANGLE NOTE: Cam Angle can be adjusted on the car without removing distributor cap. Inspection of replacement of contact points and setting of breaker gap requires removal of cap or distributor assembly removal.*

Cam Angle Setting (On Car): Operate engine at idle speed. Lift adjustment window on side of cap. Use Allen wrench (or special tool - see Note below) to turn contact point adjusting screw. Turn screw in (clockwise) to increase cam angle, out (counterclockwise) to decrease cam angle. Use dwell meter and set cam angle to 30° (limits 28-32°). *NOTE* - If dwell meter not used, approximate setting can be secured by turning adjusting screw in until engine begins to misfire and then turning screw out (counterclockwise) ½-turn (180°).

►*ADJUSTING TOOL NOTE:* Special extensions, J-6296, or J-6788, or BT-1501, may be used for convenience in adjusting cam angle on installations where distributor is not readily accessible.

CONTINUED ON NEXT PAGE

DELCO-REMY "WINDOW" DISTRIBUTORS (Continued)

Br aker Gap & Cam Angle Setting (Off Car): Distributor cap can be removed for access to contact point assembly by releasing the two cap retaining latches. Engage screwdriver in slotted head of latch, press down, turn screwdriver ¼-turn in either direction.

Breaker Gap Setting - Use Allen wrench to turn adjusting screw in or out for gap of .016". *NOTE* - Adjusting screw is spring-loaded and no locking screws are used to position the stationary contact mounting plate.

Cam Angle Setting - Operate the distributor on a testing machine, use dwell meter to set cam angle at 30° (limits 28-32°) in same manner as on car adjustment (above). *NOTE* - If testing machine and dwell meter not used, approximate setting can be secured by mounting distributor in a vise and connecting a test lamp and battery across contact points. Turn adjusting screw in (clockwise) until lamp lights (points opening), then turn adjusting screw out (counterclockwise) ½-turn (180°). *CAUTION - Always recheck cam angle after distributor installed on engine.*

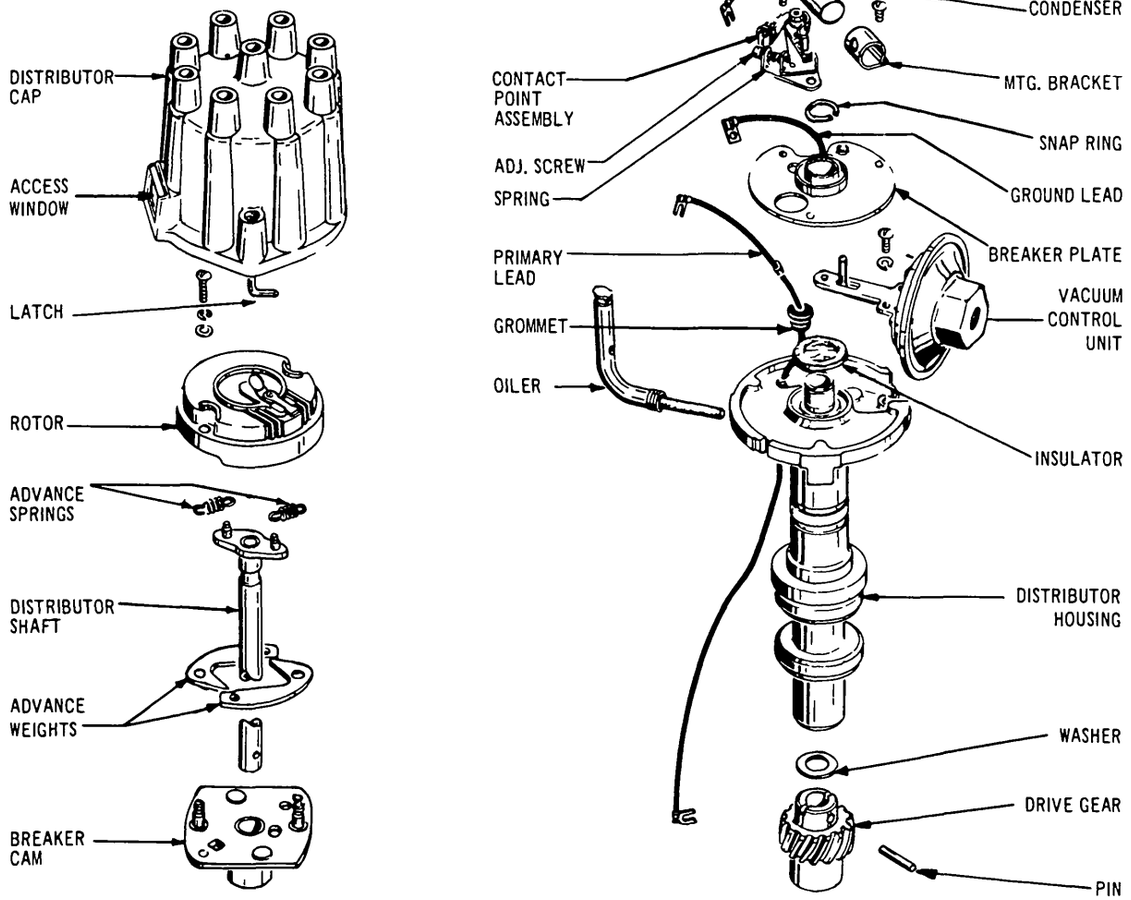
DISTRIBUTOR PARTS REPLACEMENT: Remove distributor cap by releasing latches as follows: Engage screwdriver in slotted head of latch, press down, turn screwdriver ¼ turn in either direction

R t r Removal & Installation: Rotor can be removed by taking out two screws attaching rotor to cam plate.

►*ROTOR INSTALLATION CAUTION:* Rotor can be installed in only one position (located by one square nib and one round nib on underside which must fit into corresponding holes in base plate). **Any attempt to install rotor in any other position will result in breaking r tor when attaching screws tightened.**

Contact Point Replacement: Loosen terminal screw on contact plate post and remove condenser and primary leads Take out two screws in contact set base and lift old contact set out Install new contact set When connecting leads, primary lead should be inside condenser lead and then looped over condenser lead and fastened in outer position on terminal screw (spade type lead terminals should be placed back-to-back on screw) Make certain that leads do not interfere with cap, advance weight base, or breaker advance plate Apply trace of Delco-Remy Cam & Ball Bearing Lubricant to face of breaker cam Adjust breaker gap *NOTE*—On Replacement Contact Sets, breaker arm spring tension and contact alignment are pre-set at factory and do not require adjustment

C ndenser Replacement: Remove condenser from breaker plate by disconnecting lead from contact set terminal post and taking out mounting screw in condenser bracket When installing condenser, make certain that bracket is properly located over protrusions on breaker plate and that terminal lead does not interfere with cap, advance weight base, or breaker advance plate



DISASSEMBLY: Remove rotor, weight springs and weights, file off drive gear retaining pin head, drive pin from gear and shaft and remove gear. *NOTE - On C rvair distributors, a second pin retains the two lower thrust washers on shaft. Remove this pin to remove washers before removing shaft.* Pull shaft and cam weight base assembly from housing. *NOTE - On distributors with tachometer drive, remove thrust plug and accessory drive shaft from housing before distributor drive shaft can be removed.* Remove cam and weight base from shaft. Remove condenser, contact point assembly, and cam lubricator from breaker plate. Remove snap ring and remove breaker plate. Remove vacuum unit. Remove felt washer from around housing bushing and remove gasket from housing.

Inspection: Wash all parts except cap, rotor, condenser, and vacuum unit in solvent and blow dry with air. Inspect all parts for wear, roughness, and for free operation. If shaft or bearings are worn, replace shaft and housing. *NOTE - Housing and bushings ar furnish d as an ass mbly only.* Check alignment of shaft Shaft runout must not exceed .002".

REASSEMBLY: Reverse disassembly and note the following: If lubrication in grooves at top of shaft was removed, replace with Plastilube No. 2.

Tachometer Drive Distribut rs - Add or remove shims at thrust plug to obtain .005-.010" endplay of accessory drive shaft. Pack accessory drive chamber with Delco-Remy No. 2½ grease.

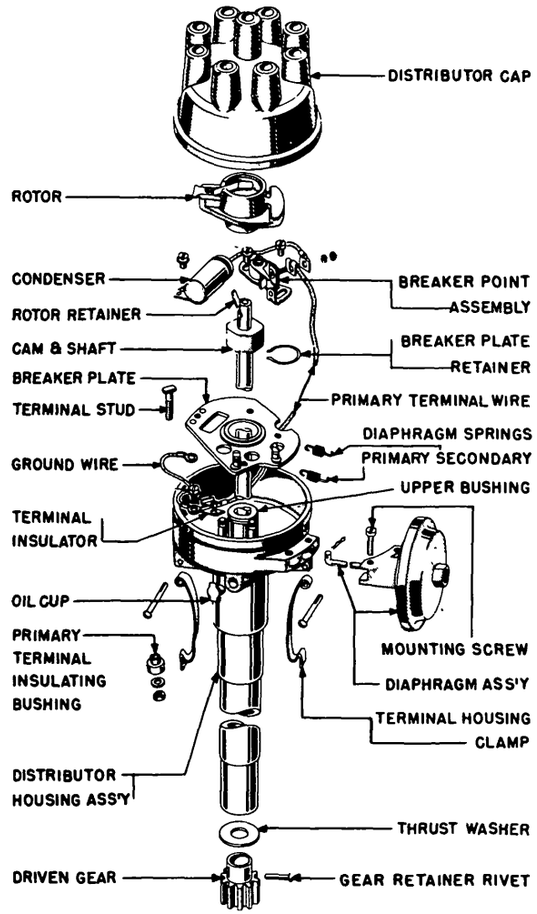
Corvair Distributors - When installing vacuum unit, do not tighten retaining screws, then install breaker plate with 23° mark in line with scribe mark on housing and tighten vacuum unit retaining screws.

DELC -REMY "WINDOW" DISTRIBUTOR ASSEMBLY

FORD MOTOR CO. "LOADOMATIC" (SINGLE DIAPHRAGM) DISTRIBUTORS

►CHANGES, CAUTIONS, CORRECTIONS

►*LINCOLN FAF-12127-B & MERCURY FAE-12127-C (Early 1954) DISTRIBUTOR OVER-ADVANCE WHEN ENGINE STARTED AT LOWER TEMPERATURE CORRECTION:* This condition noted when engine detonates excessively after starting under low temperature conditions. Install new Pin & Post Assembly, Part No. FDC-12357-A (see below), which limits advance to 15-15½°. Earlier distributors that have been reworked in production are identified by the part number prefix "ED" *CAUTION - Wh n calibrating a corrected distributor, refer to Automatic Advance Table FDD-12127-A (Lincoln), FDC-12127-A (Mercury).*



Pin & Post Ass mbly Installation - Remove distributor from engine. Remove rotor and turn primary spring adjustment post (post farthest from diaphragm) counterclockwise to remove all tension from spring and remove spring from post. Support distributor in holding fixture and carefully remove fixed adjusting post with a 1/16" pin punch. Install new Pin & Post Assembly, Part No. FDC-12357-A, so that pin is parallel to breaker plate slot when in full advance position. Attach primary spring and recalibrate distributor to specifications for distribut ors listed above.

DESCRIPTION: "Loadomatic" or pressure type distributor is a full automatic advance type in which the entire advance is provided by action of the vacuum diaphragm unit linked to the breaker plate (no centrifugal weights used). This advance action is controlled by the two diaphragm springs on the breaker plate which oppose diaphragm movement. Springs may be of equal or unequal weight, but act together to produce the desired advance curve. The diaphragm vacuum line is connected to the carburetor and terminates in two separate ports. Upper port is in carburetor venturi tube, lower port is in carburetor throat just above throttle valve edge. Vacuum at these ports and consequent suction on line varies in accordance with engine operating conditions to provide correct advance. On some carburetors, there is a nylon ball in lower port passage and/or a spark control valve to regulate the vacuum.

ADJUSTMENT: Contact Point & Cam Angle Setting - *See Car Mod l pag s for specifications.* On new points, insert a feeler gauge between points with rubbing block on the peak of a cam lobe. To adjust, loosen stationary contact lock screw. On used points, set point gap by checking cam angle since roughness of points will not allow accurate reading. Adjust by loosening stationary contact lock screw.

C ntact P int Alignment - Align points for full face contact by bending stationary contact bracket. *DO NOT b nd breaker arm.*

Br ak r Arm Spring Tensi n: *S Car Model pag s for specifications.* Check tension with spring scale hooked over movable contact and pulled at right angle to contact. Note reading as points just start to open. To adjust, loosen nut holding contact spring and move spring toward or away from breaker arm pivot as necessary.

"LOADOMATIC" DISTRIBUTOR (TYPICAL)

Spark Advance Adjustment: With distributor in a test stand, check operation of lowest and highest vacuum and RPM settings. *See Car Model pages for specifications.* If not within limits for low vacuum, adjust tension of primary spring by turning adjusting post as required. *Primary spring is farthest from vacuum unit.* If advance not within limits for high vacuum, adjust secondary spring in same manner. *NOTE - Always adjust primary spring first.* Make final check thro ughout entire range. If proper advance not obtained by adjustment of springs, replace springs or vacuum unit as necessary.

OVERHAUL

►*BUSHING WEAR TEST:* To determine shaft and bushing wear before distributor disassembled, mount distributor on test stand and operate so cam angle reading is obtained. Slide ring of a spring scale over shaft, hold scale at right angle to shaft, and exert a pull of 16 ozs. If cam angle varies more than 3°, excessive shaft and bushing wear is indicated.

►*DISTRIBUTOR HOLDING FIXTURE NOTE:* For ease in working on distributor and to prevent damage to housing and shaft, holding fixtures listed below are recommended to clamp distributor in vise.

Model	Holding Fixture No.
6 Cyl.	T52L-12132-CGD or 12132-C
V8	T52L-12132-DJD or 12132-D

DISASSEMBLY: Remove oil pump drive shaft (if equipped) by driving out retainer pin. Remove rotor and retainer, vacuum advance rod retainer, and vacuum unit. Remove condenser and contact point assembly. Release tension on advance springs and remove springs. *CAUTION - Do not distort springs.* Remove cap clamps. Drive out drive gear pin and collar pin, press gear off shaft, remove collar and slide shaft from housing. *NOTE - On tachometer drive distributors, remove accessory drive assembly. Drive out tachometer drive gear retainer pin, then press distributor shaft through top of housing and remov tachometer drive gear from bottom of housing.* Remove breaker plate lock ring retainer and remove breaker plate. Remove primary and ground wires.

Inspection: Clean all parts except points, condenser, lubricating wicks, oil seals, wiring, and vacuum unit in solvent and blow dry with air. Inspect all parts for wear, roughness, burning, distortion, etc. Replace parts as necessary. Minimum drive shaft diameter at bushing is .4675". Maximum bushing inside diameter is .4690".

►*BUSHING REPLACEMENT TOOL NOTE:* Use following tools to remove, replace, and burnish bushings:

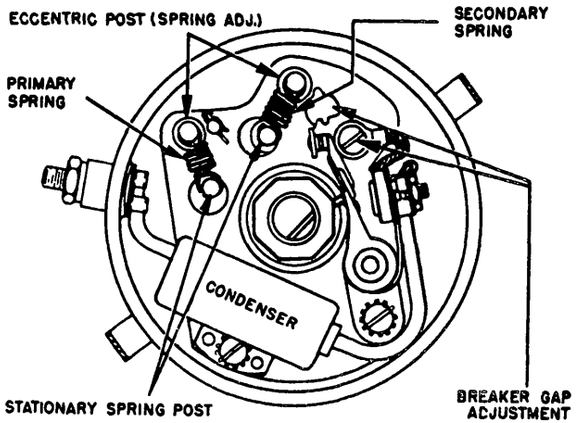
Car Model	Remover	℄Installer	Burnisher
Edsel & Comet	12132-H	12132-A	12132
All Others	12132-B1 or N	12132-A	12132

℄ - With proper adapter, 12132-A1, A3, A5, A6, A10, as applicable.

Bushing Removal: *NOTE - Some distributors have one bushing, others have upper and lower bushings. Remove lower bushing first through bottom of housing, then remove upper bushing through top of housing. Single bushing is removed in same manner as upper bushings. Procedure following is the same for all bushings.* Compress and insert slotted end of remover tool (see above) in distributor housing, expand and butt tool against bushing, then drive out bushing.

Bushing Installation: *NOTE - On single bushing distributors, install bushing according to instructions for upper bushing.* Oil lower bushing and install with installer tool (see above) until bushing is flush with lower edge of distributor housing. Oil upper bushing and install with lock ring end up with installer tool and proper

CONTINUED ON NEXT PAGE

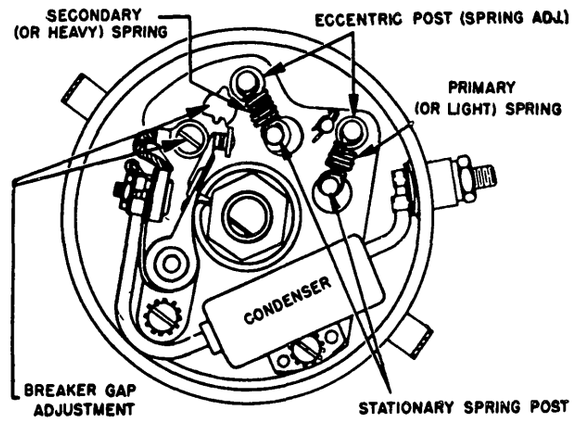


FORD MOTOR CO. "LOADOMATIC" (SINGLE DIAPHRAGM) DISTRIBUTORS (Cont.)

adapter (see above) until adapter bottoms firmly against top of distributor housing. Adapter will seat bushing to proper depth in housing. Burnish bushings to correct size.

REASSEMBLY: *NOTE - Always replace shaft and drive gear as an assembly.* Reverse disassembly procedure, installing all parts in proper order, and note the following:

Old Shaft & Gear Installation (Without Collar): Press gear on shaft until pin holes are aligned. Install pin and peen if solid type pin. Check shaft endplay between gear and housing (see table below). If endplay not within specifications, install new shaft and gear (see below).



Old Shaft & Gear Installation (With Collar): Slide collar on shaft, align pin holes, install pin and peen if solid type pin. Check shaft endplay between collar and housing (see table below). If endplay not within specifications, replace shaft and gear (see below). Press drive gear on shaft so pin holes align. Install and peen pin. Distance from bottom face of drive gear to bottom face of distributor mounting pad with all shaft endplay removed should be 4.991-4.996". If not correct, replace shaft and gear (see below). *NOTE - On tachometer drive distributors, install tachometer drive gear so pin holes align and install pin. Tachometer drive gear replaces collar on this distributor. Check endplay between cam and bushing (upper end of distributor).*

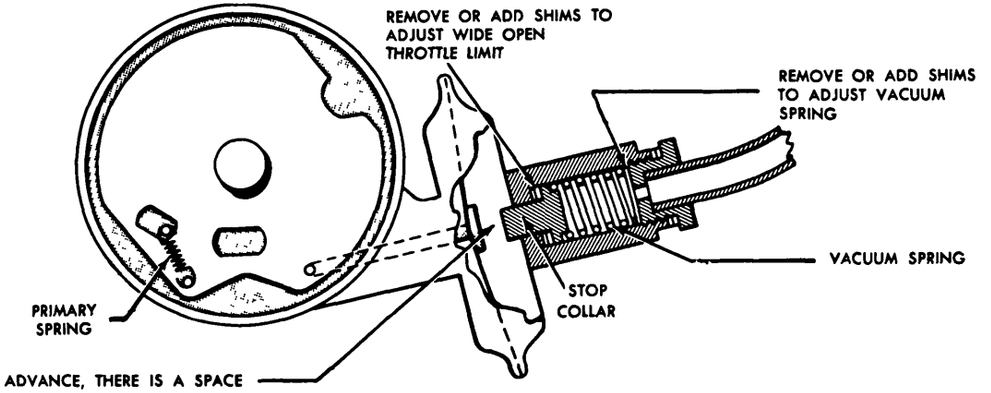
LOADOMATIC DISTRIBUTOR
COUNTERCLOCKWISE ROTATION

New Shaft & Gear Installation (Without Collar): With distributor inverted and supported, hold distributor shaft with cam against bushing so all endplay is removed. Press new gear on shaft until proper endplay (clearance between gear and housing thrust washer) is obtained. See table below. Drill 1/8" hole through shaft, install new gear retainer pin, and recheck endplay.

New Shaft & Gear Installation (With Collar): With distributor inverted and supported, insert minimum clearance feeler gauge (see Endplay table below) between backing screw (or shaft support) and remove all endplay (cam firmly against bushing). Remove feeler gauge and let shaft rest on backing screw or support. Slide collar over drive shaft and hold against distributor housing. *NOTE - On tachometer drive distributors, install tachometer drive gear so it is firmly against thrust washer inside housing.* Drill 1/8" hole in shaft, install pin to secure collar or tachometer drive gear. Check endplay (see table below). Remove all endplay from distributor shaft and press on distributor drive gear until distance from bottom face of drive gear to bottom face of distributor mounting pad with all shaft endplay removed is 4.991-4.996". Drill 1/8" hole through shaft, install and peen retainer pin. *NOTE - Tachometer driv distributor endplay is check d betw en cam and bushing.*

LOADOMATIC DISTRIBUTOR
CLOCKWISE ROTATION

Distributor Shaft Endplay



Car Model	Endplay
6 Cyl. (Except Comet & Falcon)	.005-.008"
Comet & Falcon	028"
All V8 Engines 1954-55	.020-.024"
All V8 Engines 1956-58	.022-.030"

FORD MOTOR CO. "STEP-STOP" DISTRIBUTORS

DESCRIPTION: Similar in design to previous "Loadomatic" distributors except that secondary spring and post have been eliminated and modified vacuum diaphragm has a vacuum spring, moveable stop collar and adjusting shims similar to V8 type vacuum units. Stop collar acts as a seat for vacuum spring and is located on inside end of spring with its inward travel limited by a restriction in bottom of spring housing. Projection of collar extends through restriction and is aligned at a predetermined distance with end of diaphragm rod. This design permits lower maximum advance stop for wide open throttle in addition to usual stop for road load conditions.

OPERATION: When vacuum is created in front side of vacuum chamber, diaphragm rod causes distributor advance plate to rotate counterclockwise against tension of primary spring. Plate rotates until diaphragm rod contacts stop collar. Because of vacuum spring tension much more vacuum is needed to compress spring. The part of advance curve between point where rod contacts stop collar and point where vacuum spring begins to move is the maximum advance for wide open throttle. When sufficient vacuum is applied to move vacuum spring, more advance is obtained, but at a different rate.

ADJUSTMENT: 1) Mount distributor in test stand, perform leak tests, adjust breaker arm spring tension, lubricate cam, and make sure advance plate operates freely.
2) Adjust distributor to specifications given for Test "A" in Advance Performance table. If advance not within limits, adjust primary spring.
3) Adjust distributor to specifications given for Test "B" in Advance Performance table. If advance not within limits, add or remove shims from distributor side of stop collar. *NOTE - Shims furnished in .010" & .020" thicknesses.*

FORD MOTOR CO. "STEP-STOP" DISTRIBUTOR

4) Adjust distributor to specifications given for Test "C" in Advance Performance table. If advance not within limits, add or remove shims from capscrew side of vacuum spring. Retest. If advance falls within one set of limits but not within the other, replace vacuum spring and retest. *CAUTION - Do not exceed limits given for highest RPM or engine will be damaged.*
5) Set test stand at vacuum specified for Test "D" in Advance Performance table. If advance greater than specified, replace breaker plate assembly.

►With Distributor on Test Stand

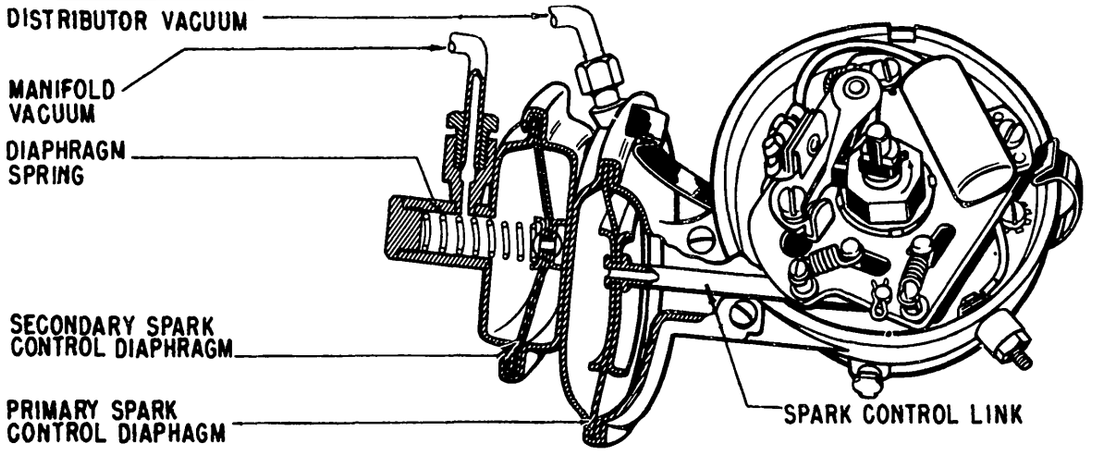
OVERHAUL: *See "Ford Motor Co. Loadomatic (Single Diaphragm) Distributors".*

FORD, LINCOLN, MERCURY "LOADOMATIC" (DOUBLE DIAPHRAGM) DISTRIBUTORS

►CHANGES & CORRECTIONS



►*SUDDEN ENGINE STOPPING (Ignition Interruption):* May be caused by defective weld at either terminal of distributor primary lead. Examine lead for good weld at terminal lug.

►*DISTRIBUTOR PRIMARY LEAD GROUND:* May be caused by end of distributor identification plate fastening screw extending through case and penetrating primary lead insulation. Correct by replacing damaged lead and filing off sharp point of screw.

►*DISTRIBUTOR DIAPHRAGM UNIT PRODUCTION CHANGE & REPLACEMENT NOTE:* New Distributor Diaphragm Unit, No. B6A-12370-B, used on later cars and can be installed on all cars as replacement. This unit has stronger diaphragm and can be identified by diecast end cover (previous type No. B6A-12370-A had stamped cover).

►*ENGINE DETONATION CORRECTION: If caused by rupture or leakage of secondary diaphragm (allowing primary diaphragm to advance spark excessively), see Distributor Diaphragm Unit Change above.*

DESCRIPTION: This "Loadomatic" type distributor is a full automatic advance type in which the spark advance is regulated entirely by vacuum differential at the carburetor. Spark advance characteristics are controlled by two breaker plate springs, working against the distributor spark control diaphragms. A secondary diaphragm is provided (farthest from distributor body) to give a rapid spark retard at the acceleration "tip-in" point. The primary diaphragm (closest to distributor body) operates in same manner as the single diaphragm type.

FORD, LINCOLN, MERCURY "DOUBLE DIAPHRAGM" DISTRIBUTOR ASSEMBLY

OPERATION: (Distributor Double Diaphragm) - The secondary spark control diaphragm forces a quick, momentary spark retard while distributor vacuun line, carburetor vacuum passages, and primary spark control diaphragm are normalizing to new pressure conditions which develop when spark control valve closes the manifold vacuum passage in the carburetor. The secondary spark control diaphragm is not connected either to the breaker plate or the primary spark control diaphragm. There is merely an air chamber between the two diaphragms. The secondary spark control diaphragm is held in an outward position by straight intake manifold vacuum working against a calibrated spring (this spring is located under the hex head plug in center of secondary diaphragm housing). Vacuum is taken from base of carburetor throttle body above the throttle valves. When throttle is opened suddenly for rapid acceleration, manifold vacuum drops quickly, and the spring loaded secondary spark control diaphragm moves toward primary spark control diaphragm. The resulting air pressure between the two diaphragms pushes the primary diaphragm inward providing a quick spark retard.

ADJUSTMENT: *See "Ignition" on Car Model pages.*

TESTING: (Distributor Double Diaphragm) - Disconnect distributor and manifold fittings at diaphragm and attach a screw-in adaptor, for use with distributor tester vacuum pump, to primary diaphragm fitting (large fitting). Adjust vacuum pump to a steady reading of 20 inches of vacuum. Connect hose to primary fitting. If reading is less than 20 inches, one or both diaphragms are leaking and should be replaced. Disconnect vacuum hose and reset vacuum pump to 3 to 5 inches of vacuum. Connect hose to diaphragm fitting and check for a steady reading of 3 to 5 inches. Replace unit if reading not steady. *NOTE - New diaphragm assemblies should be checked at both vacuum settings befor installation.*

DISTRIBUTOR OVERHAUL: *See "Ford, Lincoln, Mercury Loadomatic Distributors (Single Diaphragm)"*

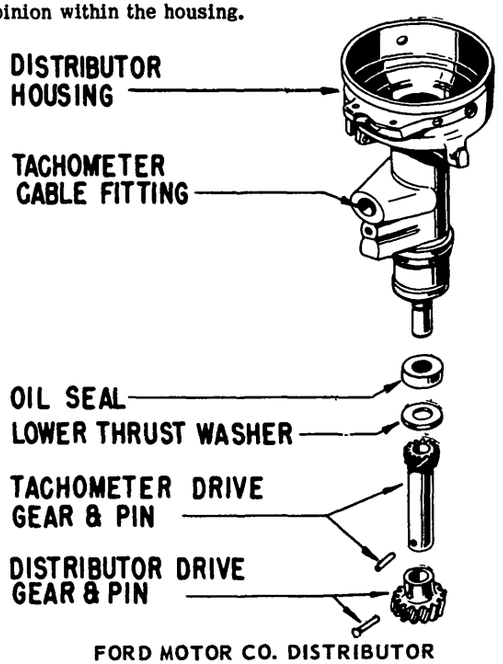
FORD MOTOR CO. (MECHANICAL & VACUUM ADVANCE) DISTRIBUTORS

►CHANGES, CAUTIONS, CORRECTIONS

►*1957 FORD 312" SUPERCHARGED ENGINE DISTRIBUTOR NOTE: This distributor has "Double Breakers". Both sets of points must be adjusted to the same gap.*

►*1957 LINCOLN & CONTINENTAL DISTRIBUTOR PRIMARY WIRE PRODUCTION CHANGE:* A new primary wire with improved insulation, Part No. B7A-12216-B, having a shiny black vinyl covering, is used in production and should be used for service replacement to correct ignition failures caused by the former cloth covered wire.

►*1957 MERCURY 368" ENGINE DISTRIBUTOR PRODUCTION CHANGE:* Distributors, Part No. FEK-12127-E (Except Turnpike Cruiser), and FEL-12127-B (Turnpike Cruiser) replace the distributors used in early production. The later type distributors have different automatic and vacuum advance curves and different primary and secondary distributor weight springs. Early type distributors can be reworked for improved performance by installing new springs and adjusting the advance to later specifications. *See "Mercury FEK-12127-C and FEL-12127-A Distributor Rework for Improved Performance" below.*



►*1957 MERCURY FEK-12127-C & FEL-12127-A DISTRIBUTOR REWORK FOR IMPROVED PERFORMANCE: (NOTE - Before reworking these distributors check the automatic and vacuum advance characteristics to determine if they have been previously reworked).* Remove the early type primary spring, Part No. B7A-12192-A, and secondary spring, Part No. FEK-12191-A and install the new primary spring, Part No. FEL-12192-A-UP, and secondary spring, Part No. B7A-12191-B. Adjust distributor automatic and vacuum advance as indicated for "Late Production" cars. *See Mercury Car Model Pages for specifications.*

DESCRIPTION: These distributors differ from previous designs in that a conventional centrifugal advance mechanism is used in conjunction with the vacuum spark control unit as described below. Some distributor models have a Tachometer drive mechanism built in the distributor.

Centrifugal Advance - Consists of two spring-loaded weights pivoted on a plate on the upper end of the distributor driveshaft. Drive pins on these weights engage slots in the base of the breaker cam subassembly so that the breaker cam is rotated by the movement of the weights. Weights move out against spring tension as distributor driveshaft RPM increases, rotating the breaker cam ahead of the driveshaft to advance the spark. With a decrease in driveshaft RPM, the springs pull the weights in and rotate the breaker cam in the opposite direction to retard the spark. Springs are identical but are adjusted for unequal tension to provide primary and secondary advance. Primary spring (greater tension) controls advance at lower engine speeds, secondary spring (less tension) controls advance at higher engine speeds. Spring tension is adjusted by bending the posts at the outer ends of the springs.

Vacuum Advance - Spring-loaded, single diaphragm type unit mounted on distributor housing and linked to breaker plate. Manifold vacuum pulls the diaphragm outward (against spring tension) and rotates the breaker plate against the direction of rotation to advance the spark. When manifold vacuum decreases, the spring returns the breaker plate to the normal position. *NOTE* - Vacuum port in carburetor is above closed-throttle position so that vacuum advance does not operate during closed-throttle idling.

Tachometer Drive - A drive gear and sleeve is pinned on the distributor shaft (replaces regular locating collar on shaft). A boss is provided on the side of the distributor housing for mounting of the tachometer driven pinion and cable assembly. The drive gear engages the pinion within the housing.

FORD MOTOR CO. DISTRIBUTOR WITH TACHOMETER DRIVE ATTACHMENT

ADJUSTMENT: Breaker Gap, Cam Angle, Breaker Arm Spring Tension, Ignition Timing, Distributor Automatic & Vacuum Advance - *See individual Car Model pages for specifications.*

Automatic (Centrifugal) Advance: Mount distributor on test set indicating distributor RPM and degrees of advance. Operate distributor in direction of rotation (counter-clockwise), increase RPM until advance begins, then decrease RPM to point where no advance indicated and set advance scale at zero. Increase RPM to first point indicated in Automatic Advance table, check advance and RPM. If advance not correct at this speed, stop distributor and adjust PRIMARY spring (see Adjustment Note below). Recheck minimum advance point. Then increase RPM to point just below maximum advance. If advance not correct at this speed, stop distributor and adjust SECONDARY spring (see Adjustment Note below). Recheck advance throughout entire speed range (first while increasing RPM, and again while decreasing RPM). Readjust as necessary.

►*AUTOMATIC ADVANCE SPECIFICATION NOTE: See individual Car Model pages for specifications.*

►*PRIMARY & SECONDARY ADVANCE SPRING ADJUSTMENT NOTE:* Springs can be identified by turning distributor to point where advance spring directly under adjustment slot in breaker plate, engaging a wire hook in the spring, and moving spring up and down to check spring tension. Primary spring will have greater tension with distributor at rest (secondary spring will be slack or not under tension at this point). To adjust, insert screwdriver blade through the adjustment slot, bend spring bracket (stationary post on base plate) outward to increase tension and decrease advance or inward to decrease tension and increase advance.

Vacuum Advance: Vacuum unit should be checked for free operation and diaphragm leakage whenever engine is tuned up. Vacuum advance performance can also be checked and adjusted as directed below.

Free Operation - Manually rotate breaker plate in direction of rotation (counter-clockwise). Plate should turn without binding and return to original position when released. If binding indicated, remove plate and clean and lubricate it as required.

Vacuum Diaphragm Leakage - Use vacuum source on distributor test set, set vacuum to highest possible figure. Connect vacuum line to fitting on distributor vacuum unit. Vacuum gauge reading should not fall off. Lower vacuum reading indicates diaphragm leak and diaphragm assembly should be replaced.

Vacuum Advance Check & Adjustment - Mount distributor on test set. After centrifugal advance has been checked and adjusted, operate distributor at constant RPM to eliminate centrifugal advance variations (see Specifications). Connect vacuum line to distributor vacuum unit fitting, set vacuum at first figure in specification table, check advance. If advance not correct, change calibration washers located at outer end of spring under vacuum connection. Recheck vacuum advance throughout entire range (*CAUTION* - Keep distributor RPM constant, vary vacuum). If all points not within limits, incorrect spring tension or vacuum leaks in diaphragm chamber or lines is indicated.

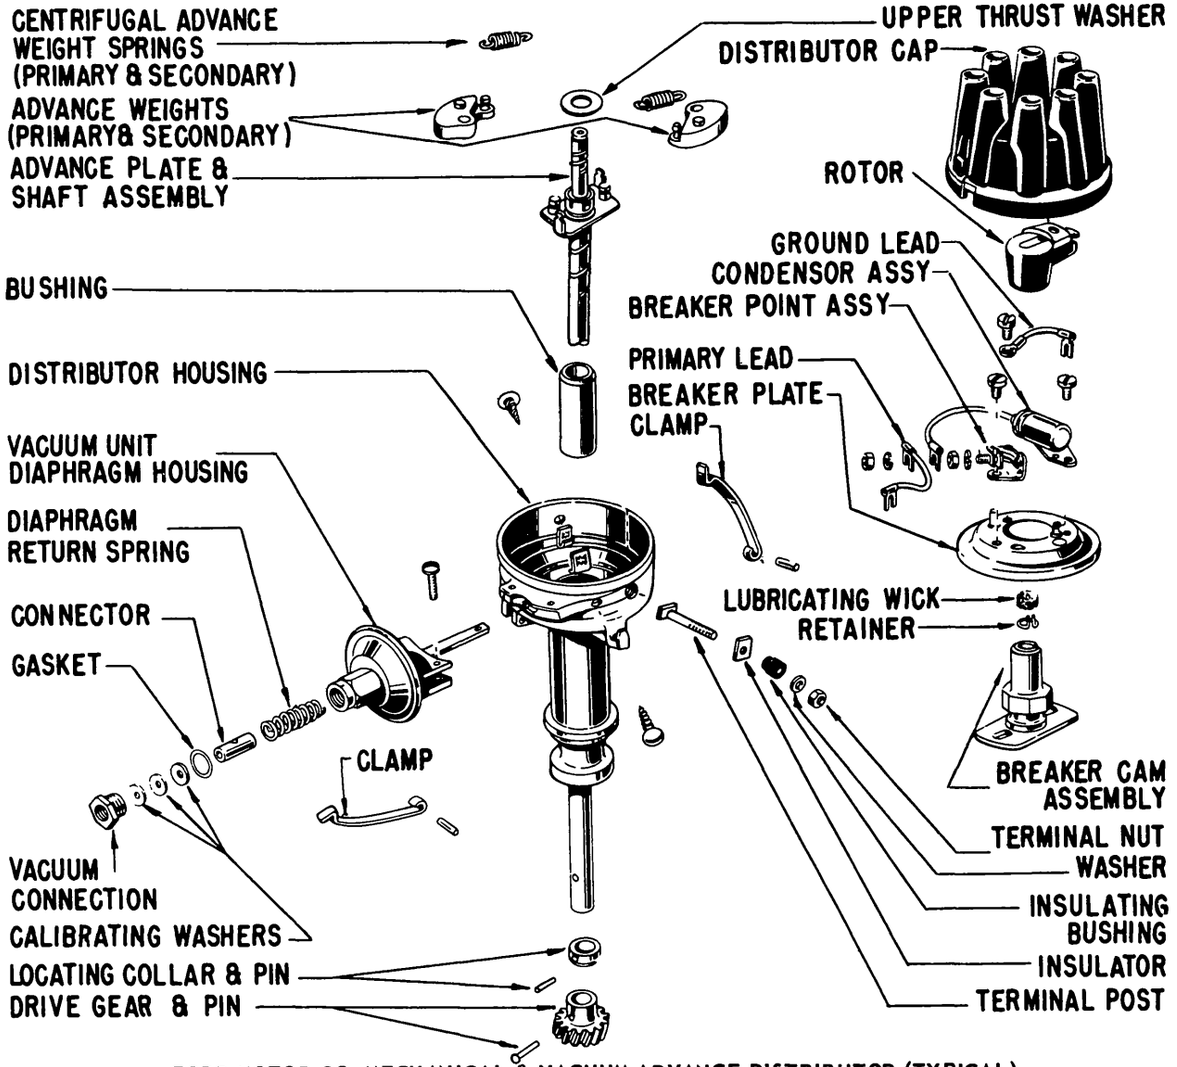
►*VACUUM ADVANCE SPECIFICATION NOTE: See individual Car Model pages for specifications.*

►*VACUUM UNIT ADJUSTMENT NOTE:* Decrease number or thickness of calibration washers to increase vacuum advance, increase number or thickness of washers to decrease vacuum advance.

SERVICING: Breaker Point Replacement - Breaker Point Assembly consists of Mounting Bracket & Stationary Point Assembly, Breaker Arm, and Primary Lead and complete unit can be replaced without removing distributor from engine. To remove unit, disconnect primary and condenser lead, take out screws mounting unit on

CONTINUED ON NEXT PAGE

FORD MOTOR CO. (MECHANICAL & VACUUM ADVANCE) DISTRIBUTORS (Cont.)



breaker plate. To install unit, connect primary and condenser leads to point assembly terminal, position unit on breaker plate, install and tighten hold-down screws (*CAUTION* - Ground lead terminal must be attached to screw at breaker arm pivot end of bracket).

Vacuum Advance Unit Removal & Installation - Remove spring clip securing diaphragm link to breaker plate, take out two screws mounting vacuum unit on distributor housing, remove vacuum unit by withdrawing link through slot in housing.

Breaker Plate Removal & Installation - After removing vacuum advance unit (above), remove nut, washer, and bushing from primary terminal screw, remove terminal screw and insulator from within housing. Remove two screws and retainers in housing which retain breaker plate assembly, then lift breaker plate assembly out.

►*BUSHING WEAR TEST:* To determine shaft and bushing wear before distributor disassembled, mount distributor on test stand and operate so cam angle reading is obtained. Slide ring of a spring scale over shaft, hold scale at right angle to shaft, and exert a pull of 16 ozs. If cam angle varies more than 3°, excessive shaft and bushing wear is indicated.

OVERHAUL: Disassembly - Remove spring clip and disconnect diaphragm link at breaker plate. Disconnect and remove diaphragm assembly from distributor base. Remove primary terminal screw, bushing, and insulator. Remove breaker point assembly and condenser, then remove two screws and retainers securing breaker plate in housing and remove plate. Remove lubricating wick from cam assembly, cam assembly retainer, cam assembly, and upper thrust washer. Remove distributor weight springs. *(NOTE - Mark the secondary spring and bracket to which it is attached for identification at reassembly).* If gear and shaft are to be reused, mark both parts so pin holes can be aligned for reassembly. Remove driven gear roll pin, then remove gear. On cars with a tachometer attachment, align tachometer drive gear roll pin with holes in distributor base, then secure distributor in a vise and remove roll pin. If gear is to be reused, mark gear and shaft so holes may be aligned at reassembly. Using an arbor press, support the assembly so shaft is clear of support plate, then press shaft out of tachometer gear and housing. Remove gear and lower thrust washer, then using an arbor press (and a shaft smaller in diamet r than the bushing outer diameter), press bushing and oil seal out of housing. On conventional distributors, remove shaft collar roll pin, then press shaft out of collar and housing and remove distributor shaft bushing in same manner as for distributors with tachometer drive.

FORD MOTOR CO. MECHANICAL & VACUUM ADVANCE DISTRIBUTOR (TYPICAL)

Inspection: Inspect all parts for damage or wear and replace as necessary. Check distributor shaft for wear at the bushing. Minimum allowable shaft diameter is .4675". Maximum allowable inside diameter of bushing is .4690". Clean all parts before reassembly.

►*BUSHING REPLACEMENT TOOL NOTE:* Use following tools to remove and replace bushings; **Remover** 12132-B1 or N; or 12132-H1 & H2. **Installer** T57L-12120-A; or 12132-A, A1, A2, A3, A5, A6, A10.

R assembly: Install new bushing with the proper tool and adapter (see Tool Note above) until adapter bottoms against the distributor housing. The correct position of bushing is .009" above the top of the distributor housing. Burnish bushings to the proper size with Tool 12132. On distributors with tachometer drive, install a new oil seal. *(NOTE - If a new shaft is being installed, see "N w Shaft & G ar Installation" below).* On distributors with tachometer drive, when the old gear and shaft are to be installed, install lower thrust washer, then install tachometer drive gear on shaft. Press gear into place until it bottoms on thrust washer. Align holes in gear, shaft and housing and install a new roll pin. On conventional distributors, place collar in position on shaft, then align holes in collar and shaft and install a new roll

CONTINUED ON NEXT PAGE

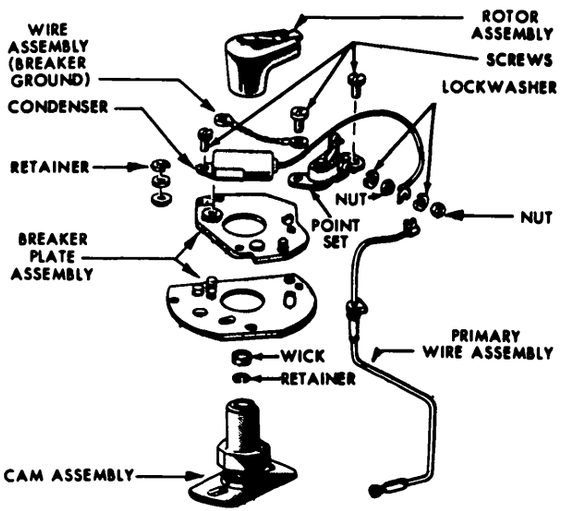
FORD MOTOR CO. (MECHANICAL & VACUUM ADVANCE) DISTRIBUTORS (Cont.)

pin. Check shaft endplay with a feeler gauge placed between automatic advance stop plate and top of bushing. If endplay is not within limits of .022-.030", replace the shaft. On all distributors, press drive gear on shaft, using the marks made on gear and shaft at disassembly, to align the pin holes. Check gear location which should be 4.991-4.996" (272", 292" 312" & 368" Engines); 5.111-5.116" (332", 352", 361". 383", 410", & 430" Engines) between the bottom face of gear and bottom face of distributor mounting pad with gear pushed toward distributor base so there is no endplay. Install roll pin. *(NOTE* - Shaft and gear must be replaced as an assembly. Do not replace one part without replacing the other). Install weights and springs making sure that secondary spring marked at disassembly is replaced in the proper location. Fill groove of weight pivot pin with ball bearing lubricant. Lubricate inside of cam assembly with ball bearing lubricant, then install thrust washer, cam, and spring retainer. Lightly oil cam lobes, then saturate wick with SAE 10 engine oil and install wick in cam assembly. Lubricate breaker plate bearings and install breaker plate. Install condenser, breaker points and plate retainers. Be sure ground wire lug is attached to breaker plate attaching screw. Install primary wire and insulator on terminal screw and install bushing and screw in distributor base. Install diaphragm assembly. Align distributor points, adjust spring tension and point gap. Adjust automatic and vacuum advance.

New Distributor Shaft & Gear Installation: Oil the shaft and slide it into distributor body. Attach Distributor Shaft Support, Tool T57L-12390-A (Detail 1) or equivalent, to distributor and place distributor in Holding Fixture, Tool T52T-12132-DJD or equivalent, and place assembly in press. Insert a .022" feeler gauge between automatic advance stop plate and top of bushing. Tighten backing screw on support tool enough to remove all shaft endplay. On distributors with tachometer drive, install lower thrust washer, then install tachometer drive gear on shaft and press it into position until it bottoms on thrust washer. Support shaft and align holes in shaft and distributor base, then drill a 1/8" hole through shaft using hole in drive gear as a pilot. Install roll pin. On conventional distributor, place collar in position and support the shaft. Hold collar against distributor housing and drill a 1/8" hole through shaft, using hole in collar as a pilot. On all distributors(support tool .022" feeler gauge still installed), press drive gear into position using an arbor press. Drill a 1/8" hole through gear and shaft, using the hole in gear shoulder as a pilot, then install a new roll pin. Remove support tool and feeler gauge and complete distributor assembly as indicated above.

EDSEL, FORD, LINCOLN, MERCURY "PIVOTED PLATE" DISTRIBUTORS

DESCRIPTION: This distributor is similar in design to the previous centrifugal automatic advance type except for the "pivoted" type breaker plate which is mounted on the stationary sub-plate. The breaker plate contains a brass bushing which is fitted to a pivot pin on the sub-plate and rotates on nylon contact buttons when actuated by the vacuum spark control which is linked directly to the breaker plate.



►*ADJUSTMENT SPECIFICATION NOTE: See "Ignition" on individual Car M d l pages.*

ADJUSTMENT: *S "Ford Motor Co. Mechanical & Vacuum Advanc Distributors".*

►*DISTRIBUTOR DWELL VARIATION NOTE:* Dwell variation not to exceed 6° is permissible on this type distributor providing it is caused by moving parts of the breaker plate and vacuum chamber arm. After adjusting dwell to specifications at engine idle speed (250 RPM on distributor) and zero vacuum, the dwell should not vary beyond 6° while advancing to maximum vacuum advance, with distributor speed remaining at 250 RPM. Variations above 6° can be caused by bent vacuum chamber arm, loose fit between arm and pivot plate pin, or a loose pivot plate pin.

OVERHAUL: *See "Ford Motor Co. Mechanical & Vacuum Advance Distributors" and note Breaker Plate and Sub-Plate Removal below.*

BREAKER PLATE & SUB-PLATE REMOVAL: Remove retainer from vacuum unit arm, then remove vacuum unit. Remove primary wire spade connector from terminal and push grommet insulator into distributor and pull primary wire through hole in housing. Remove contact points and condenser, then remove breaker plate retainer, flat washer and spring washer and lift breaker plate from sub-plate. Sub-plate can then be removed after removal of the two retaining screws.

FORD "PIVOTED PLATE" DISTRIBUTOR

AUTOLITE ALTERNATOR & REGULATOR

Car Model	Alternator No.	Regulator No.	Polarity
Checker	ALD-5001	VBT-6201A	Neg.
Willys	ALC-5001	Ⓒ VBS-6201A	Neg.

Ⓒ - With charge indicator light relay.

►CHANGES, CAUTIONS, CORRECTIONS

►*BATTERY INSTALLATION, BATTERY CHARGING, OR USING A BOOSTER BATTERY TO START ENGINE CAUTION: Reversed polarity or excessive voltage will result in extensive damage to alternator system. NOTE THE FOLLOWING TO PREVENT DAMAGE.*

Battery Installation - Alternator polarity (see above) determines which battery terminal is grounded. For negative polarity alternators, **negative** battery terminal must be grounded. *DO NOT REVERSE BATTERY LEADS or rectifiers will be damaged.*

Charging Battery - If a "Fast Charger" is used, both of the car's battery cables must be disconnected from battery. *DO NOT use a "Fast Charger" to provide starting voltage.*

Booster Battery (Used To Start Engine) - Booster battery **must** be connected with negative lead to negative terminal of battery and positive lead to positive terminal of battery. *DO NOT REVERSE BATTERY LEADS.*

DESCRIPTION: Main alternator components are the stator, rotor, slip ring end housing, drive end housing and rectifiers (diodes). Alternator voltage is controlled by varying the field current through a double contact voltage regulator unit. Because the rectifiers permit current flow in only one direction, no current can flow from battery to alternator and no circuit breaker (cutout relay) is needed. The self-limiting current characteristics of the alternator eliminate the need for a current regulator.

Stator - Consists of a laminated iron core with three phase windings electrically 120° apart wound in slots around inside circumference. A pair of leads are connected to each of the three points of the windings and one of each pair of leads connects to a negative rectifier and one to a positive rectifier.

Rotor - Consists of a single field coil encased between two four-fingered overlapping iron sections assembled on a shaft. The two ends of field coil are connected to two slip rings insulated from each other and the shaft. Battery is connected to field coil through brushes and the slip rings.

Slip Ring End Housing - Supports rectifier heat sinks, pre-lubricated roller bearing for rotor shaft, brush holders and brushes, and field and output terminals.

Drive End Housing - Supports pre-lubricated ball bearing for rotor shaft. Through bolts hold entire assembly together.

Rectifiers - Six silicone diode rectifiers are pressed into heat sinks in slip ring end housing. Three rectifiers have negative polarity and their heat sink is grounded to end housing. The other three rectifiers have positive polarity and their heat sink is insulated from end housing and connected to alternator output terminal.

SPECIFICATIONS

Performance Data - Cold (70°F)

Alternator	Amperes	Volts	Alt. RPM
ALD-5001	38 min.	14.2	Ⓒ 4200
ALC-5001	42 min.	14.2	Ⓒ 4200

Ⓒ - 1750 Engine RPM.

Rotation - Clockwise at drive end.

Rated Output - 40 Amps. (ALD-5001), 45 Amps. (ALC-5001).

Field Coil Draw - 2.34-2.42 amps. (ALD-5001), 2.32-2.43 amps. (ALC-5001) at 10.0 volts and 70°F.

Capacitor Capacity - .1 mfd.

TROUBLE SHOOTING & DIAGNOSIS

ALTERNATOR DOES NOT CHARGE: Drive belt loose. Brushes or slip rings worn. Brushes sticking. Field or charging circuits open. Rectifiers open. Stator windings open.

LOW OR UNSTEADY CHARGING RATE: Drive belt loose. High resistance in charging circuit, battery terminals or engine-to-body ground strap. Stator windings open.

LOW OUTPUT & LOW BATTERY: High resistance in charging circuit. Regulator setting too low. Rectifier shorted or open. Stator winding grounded.

EXCESSIVE CHARGING RATE: Regulator setting too high or contacts stuck. Regulator base not grounded. Regulator winding open. Rectifier open.

REGULATOR CONTACTS OXIDIZED: Regulator setting too high or air gap incorrect. Rotor field coil winding shorted.

REGULATOR CONTACTS BURNED: Regulator setting too high. Rotor field coil winding shorted.

REGULATOR COIL WINDING BURNED: Regulator setting too high.

ALTERNATOR NOISY: Alternator mountings loose. Bearings worn. Drive belt worn. Interference between rotor fan and stator leads or rectifiers. Rotor or rotor fan damaged. Rectifier open or shorted. Stator winding open or shorted.

TESTING

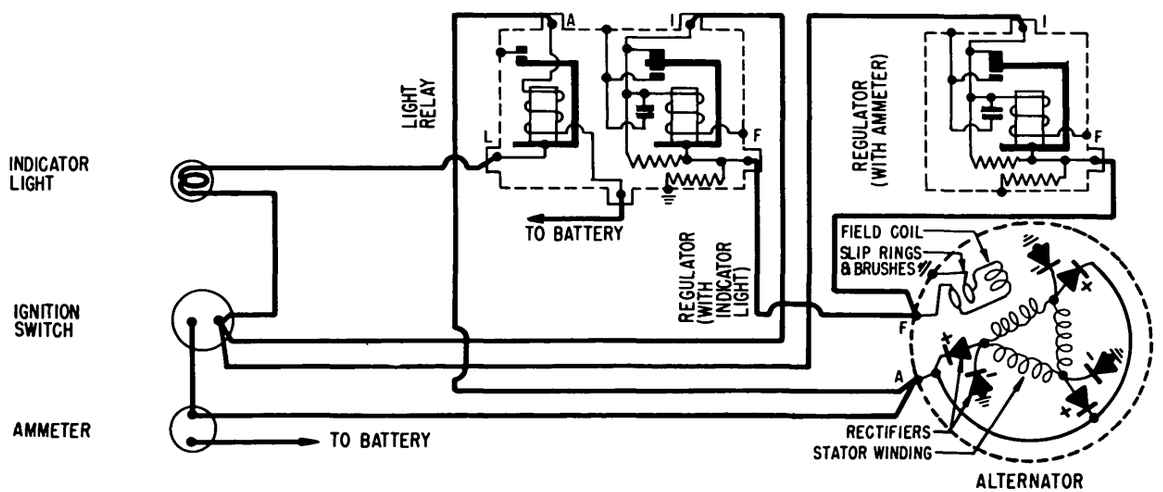
►*CAUTION:* **1)** *Do not ground field circuit between alternator and voltage regulator as regulator will be damaged.*

2) *Do not ground alternator output terminal or alternator and circuit will be damaged (no circuit breaker used and battery applied to output terminal at all times).*

3) *Do not operate alternator on open circuit with field winding energized.*

4) *Do not polarize alternator as it is not required and doing so will damage entire system.*

5) *Before making test connections, ignition switch must be off and battery ground cable disconnected from battery.*



ALTERNATOR IN CAR: With battery fully charged and engine at normal operating temperature, test circuits as follows:

Charging Circuit Resistance: **1)** Connect an ammeter in series between alternator output terminal and charging circuit lead with lead disconnected from terminal. Connect a voltmeter across charging circuit (negative lead of voltmeter to positive terminal of battery and positive lead of voltmeter to alternator output terminal lead). Disconnect lead from regulator field terminal and from alternator field terminal. Connect a jumper wire between alternator field and output terminals. Connect battery ground cable and adjust engine speed and electrical load to obtain 10 amperes in charging circuit. Voltmeter reading should not exceed .3 volt. If more, inspect, clean, and tighten all connections in charging circuit.

2) With same conditions as above, connect voltmeter from negative (grounded) battery terminal to alternator frame, and then from alternator frame to regulator base. With 10 amperes in charging circuit, voltage reading in either case should not exceed .04 volt. If more, correct high resistance ground connections.

Current Output: Leave ammeter and jumper wire connected as in "Charging Circuit Resistance" above. Connect voltmeter with negative lead to ground at alternator frame and positive lead to alternator output terminal. Connect a carbon pile rheostat across battery and a tachometer to engine. Adjust engine to 1750 RPM and rheostat to obtain 14.2 volts on voltmeter. Current output shown on test ammeter should be within specifi-

CONTINUED ON NEXT PAGE

AUTOLITE ALTERNATOR & REGULATOR INTERNAL WIRING DIAGRAM

AUTOLITE ALTERNATOR & REGULATOR (C ntinued)

cations (see Performance Data above) A slightly low reading may mean an open rectifier and a considerably lower reading may mean a shorted rectifier,

ALTERNATOR OFF CAR: Field Coil Draw (Te sting For Shorted R tor) - Connect an ammeter and a rheostat in series between outer slip ring and battery Connect other battery terminal to inner slip ring Connect a voltmeter lead to each slip ring With rheostat, adjust voltage to 10 volts and read field current draw on ammeter If higher than specifications (see above) rotor field coil winding is shorted

R tor Test (F r Grounds): Make test with a 110-volt test bulb with one probe on a slip ring and other probe on rotor core If bulb lights, rotor winding is grounded

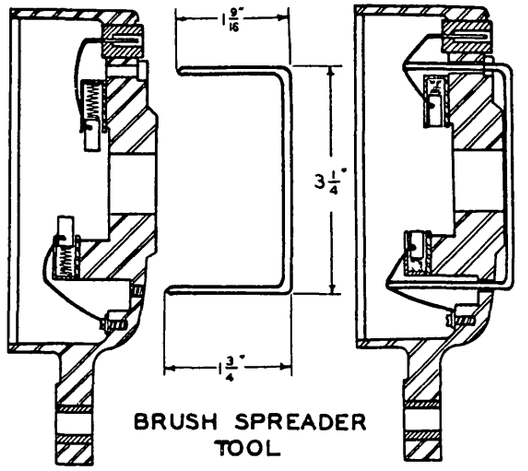
Stat r Test: Test for shorted windings with an internal-external growler Test for grounds with a 110-volt test bulb and test probes *Make both tests with stator leads disconnected from rectifiers*

Rectifi r (Di de) Test: *Make initial test without disconnecting stator leads from rectifiers This will eliminat need for complete disassembly To find which rectifier is bad, stator leads must be disconnected and each rectifier tested individually* Use a No 57 test bulb in series with a 12-volt battery and test probes Touch one test probe to rectifier heat sink and other probe to a rectifier lead in same heat sink Reverse the probes If lamp lights in **one** direction, rectifier is good If lamp **does not** light in either direction, rectifier is open If lamp lights in **both** directions, rectifier is shorted

►*RECTIFIER TESTING TOOL NOTE Diode Testing Tool C-3829 is available for testing rectifiers without disconnecting stator leads*

OVERHAUL

►*TOOL NOTE* Tools listed in following procedures are Miller Manufacturing Co tools Similar tools are also available from Draf Tool Co as follows



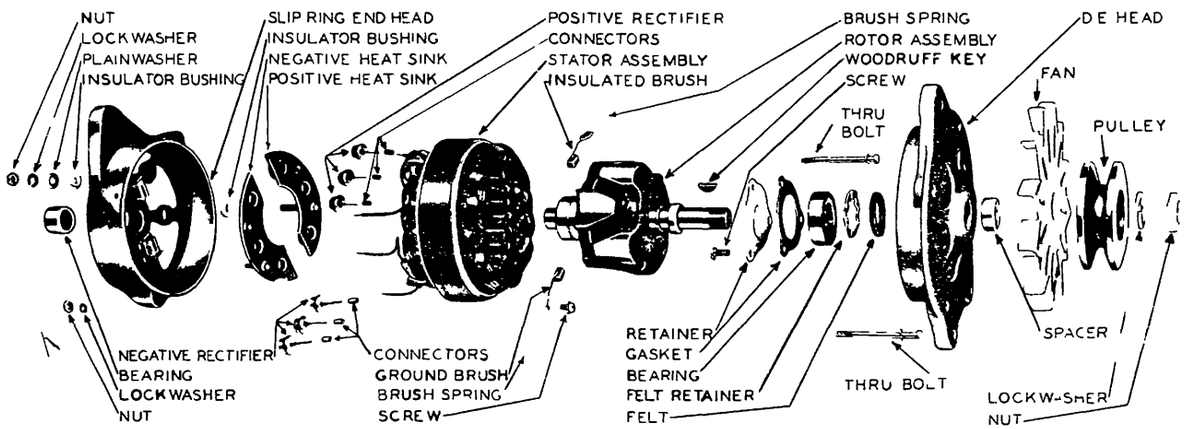
T ol Nam	Draf No.	Miller No.
Drive End Bearing Installer	VA-603	C-3769
Roller Bearing Remover	VA-604	C-3770
Roller Bearing Installer	VA-605	C-3770
Housing Support	VA-606	C-3770
Rectifier Remover Support	VA-607	C-3771
Rectifier Remover	VA-608	C-3771
Rectifier Installer	VA-609	C-3772

DISASSEMBLY: Remove through bolts, tap end housings lightly with soft hammer to separate them from stator, and remove drive end housing and rotor assembly Disconnect positive and negative rectifier heat sink studs from end housing and remove stator If brushes are worn to 5/16" or less, replace them Grip insulated brush at brass terminal and pull it from field terminal insulated bushing Remove ground brush lead attaching screw *Do not lose brush springs when removing brushes from holders* Clamp rotor in a vise (with protective jaws), remove pulley with puller or arbor press, and remove fan and woodruff key from shaft Remove shaft from drive end housing and bearing assembly with a puller which grips under bearing retainer plate *CAUTION - Do not support housing and press on rotor shaft as end housing and retainer screws will be damag d* Remove screws from retainer plate and press drive end bearing from housing with Tool C-3769 Remove roller bearing from slip ring end housing with Tool C-3770

Rectifier R plac ment: *NOTE - Positive rectifiers have red marks, negative rectifiers have black marks Positive heat sink has larger studs All rectifiers are replaced in same manner* Cut rectifier wire as near crimped sleeve connector as possible Support heat sink on Support Tool C-3771 and press rectifier out of heat sink with Remover Tool C-3772 *CAUTION - Do not hammer on tool or rectifier will be damaged Use a press only* To install rectifier, support heat sink with Support Tool C-3771 and press rectifier into sink with Installer Tool C-3772 Strip insulation on stator leads about ¼" and connect them to rectifiers by crimping connector sleeves *CAUTION - DO NOT solder connections as heat will damage rectifiers*

REASSEMBLY: *NOTE - Bearings are pre-lubricated and no further lubrication is required* 1) Install needle roller bearing in slip ring end housing so enclosed end of bearing is flush with outer surface of housing Use same tools used for removal Install felt washer and retainer into drive end housing and press ball bearing into housing (use a block of wood so pressure is exerted on bearing outer race only) Install retainer plate and gasket on end housing With snap ring and retainer on rotor shaft, press housing on shaft with Tool C-3769 which fits over shaft and against bearing center race Bearing must be against snap ring retainer Install spacer, woodruff key, fan and pulley and pulley nut

2) Install brush springs and brushes Ground brush is fastened to end housing with a screw Insulated brush has blade terminal which is pushed into slot in field terminal insulator bushing and a tab on blade terminal snaps into insulator bushing Install both rectifier heat sinks into end housing and install insulator bushings, washers and nuts Push stator into housing by hand Install drive end housing and rotor assembly into slip ring end housing and stator assembly using brush spreader tool as shown in illustration *CAUTION - Make sure through bolt holes line up as no locator pins are used* Install through bolts Remove brush spreader tool and see that brush leads do not drag on rotor and that rotor turns freely when rotated by hand .



VOLTAGE REGULATOR

DESCRIPTION Regulator - Field control type Temperature compensated, vibrating type voltage regulator with two sets of contacts using a common armature Regulator operates on either upper or lower contacts (both sets never in operation at same time) depending on load and battery requirements as follows

Upper Contact Operation (Low Speed & High Load) - Armature travel opens and closes upper contacts, cutting regulator resistance in and out of field circuit, and limiting alternator field current

Lower Contact Operation (High Speed & Low Load) - Armature travel opens and closes lower contacts, grounding the regulator field terminal and bypassing alternator field coil (contacts closed), or cutting resistance in field (contacts open), and limiting field current

CONTINUED ON NEXT PAGE

AUTOLITE ALTERNATOR ASSEMBLY - TYPICAL (EXPLODED)

AUTOLITE ALTERNATOR & REGULATOR (C ntinu d)

Indicator Light Relay: On cars with a charge indicator light in place of an ammeter a relay is used to operate the light. Relay has a single heavy winding in series with charging circuit with a moveable contact on an armature and a grounded stationary contact. Relay contacts are in series with indicator light which is connected to battery through ignition switch. With ignition switch on, light is grounded through contacts & lights up. When alternator charges, current flow through relay winding pulls armature down, opening the contacts and making light go out as long as alternator is charging.

CHECKING & ADJUSTING (ON CAR): Regulator - Disconnect alternator output terminal and install an ammeter between lead and terminal. Connect a voltmeter positive lead to regulator "BAT" terminal and negative lead to alternator frame. Adjust engine speed to 750 RPM and adjust load so there is a 10 ampere charge rate. Operate for 15 minutes to stabilize temperature. Note voltmeter reading. Cycle system by stopping and restarting engine and increase engine speed to 1500 RPM. Turn off all lights and accessories. Voltage should increase and amperage decrease. Voltage difference between readings of both tests should be .1-.3 volt. If greater or less, remove cover and move stationary contact support up or down (loosen support screw). Raising support will increase voltage. Replace cover, operate engine at 750 RPM and note voltage reading which should be as in table below. To adjust, bend lower spring hanger. *CAUTION - Do not short circuit between spring hanger and base or spring. Use an insulated bending tool.*

►*AMBIENT TEMPERATURE NOTE: The ambient temperature is the temperature registered on a reliable thermometer positioned 2" from regulator cover.*

Voltage Setting - Ambient Temp.

Temp. (°F)	Voltage	Temp. (°F)	Voltage
50°	14.1-14.5	110°	13.7-14.1
80°	13.9-14.3	140°	13.5-13.9

Indicator Light Relay: Disconnect field lead from both alternator and regulator. Connect an ammeter between disconnected alternator output terminal lead and alternator output terminal. Connect a carbon pile rheostat from output terminal lead to alternator field terminal. *NOTE - If dash indicator light cannot be seen during this test, use a 12-volt test lamp with a No. 57 bulb between regulator "L" and "B" terminals.* With rheostat resistance turned in, bring engine speed to 800 RPM and slowly turn resistance out of circuit until indicator light goes out. Ammeter reading should be as indicated below. To adjust, bend lower armature spring hanger. Increasing spring tension raises setting.

R lay Opens - 2.0-2.5 amperes.

Relay Closes - 1.5 amperes minimum.

ADJUSTMENTS (OFF CAR): *NOTE - Regulator must be reinstalled and final "On Car Adjustments" (see above) made after following "Off Car" adjustments completed.*

Regulator Lower Contact Gap: .010" measured between lower moveable contact and lower stationary contact with upper contacts closed. To adjust, bend upper stationary contact arm.

Regulator Air Gap (Upper Contacts): .034-.038". Check air gap with test lamp (No. 57 bulb) in series with battery between regulator field terminal and regulator base. Insert a .034" wire gauge between armature and magnet core on contact side of brass stop rivet. Press armature down against gauge. Lower moveable contact should barely touch lower stationary contact and lamp should light. Insert a .038" wire gauge in same position. Light should go out. To adjust, loosen stationary bracket attaching screw and move bracket up or down.

Indicator Relay Air Gap: .015-.020" measured with flat gauge between armature and magnet core. To adjust, bend stationary contact arm up or down.

CHRYSLER CORP. ALTERNATOR & REGULATOR

CHRYSLER	Chrysler No.
Imperial & 300F	① 2095100
VALIANT	
Std. Engine	② 2095060
Hyper Pack Engine	② 2095557

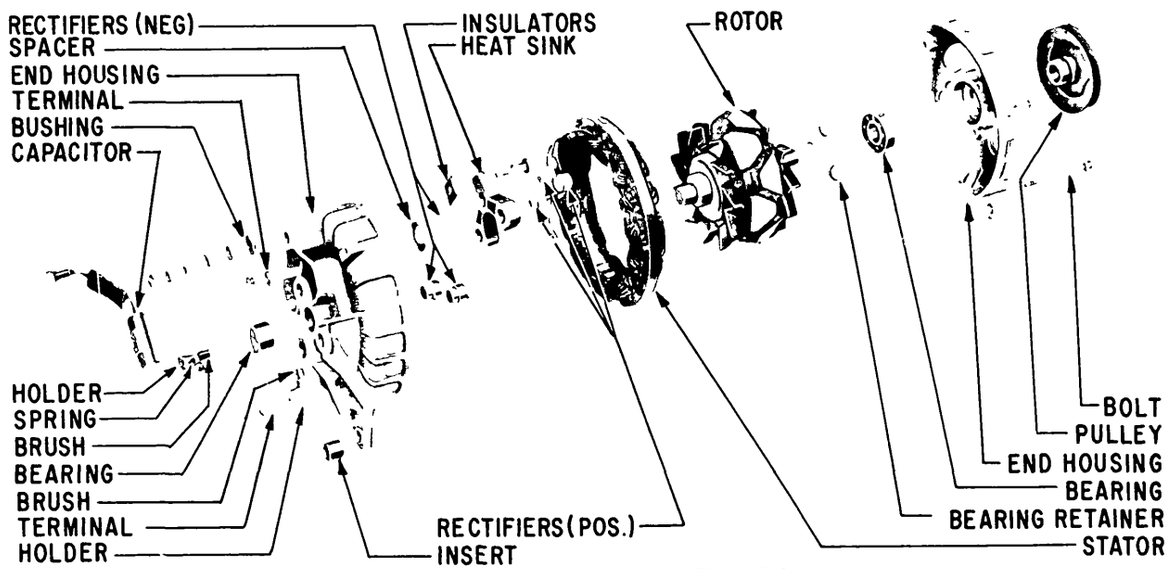
① - Use Part No. 2095300 for service replacement.
② - Use Part No. 2095000 for service replacement.

►CHANGES, CAUTIONS, CORRECTIONS

►*BATTERY INSTALLATION, BATTERY CHARGING, OR USING A BOOSTER BATTERY TO START ENGINE CAUTION: Reversed polarity or excessive voltage will result in extensive damage to alternator system. NOTE THE FOLLOWING TO PREVENT DAMAGE.*

Battery Installation - Negative battery terminal must be connected to GROUND. Positive terminal must be connected to starter lead. *DO NOT REVERSE BATTERY LEADS.*

Charging Battery - If a "Fast Charger" is used, both of the car's battery cables must be disconnected from battery. *DO NOT use a "Fast Charger" to provide starting voltage.*



Booster Battery (Used To Start Engine) - Booster battery **must** be connected with negative lead to negative (ground) terminal of battery and positive lead to positive terminal of battery. *DO NOT REVERSE BATTERY LEADS.*

►*EXCESSIVE AMMETER FLUCTUATION CORRECTION:* For tests and voltage regulator modification necessary, see *"Voltage Regulator" below.*

►*ALTERNATOR OUTPUT TERMINAL GROUNDING & INSULATOR CAUTION:* Output terminal of alternator must not be grounded under any circumstances (will severely damage alternator and regulator). To prevent accidental grounding of terminal, make sure that Output Terminal Insulator, Part No. 2258754, is installed on "BAT" terminal of alternator.

DESCRIPTION: Main alternator components are the two end housings, stator, rotor, and rectifiers. Housings are vented at both ends and around the circumference and held together by three through bolts. The rotor consists of a field coil encased between two six-fingered, overlapping sections which are the pole pieces, and produces a 12 pole magnetic field. Ends of the field coil are connected to slip rings and the battery is connected to field windings through brushes and the slip rings. The rotor shaft is supported at drive end by a ball bearing and at the opposite end by a roller bearing. Both bearings are pre-lubricated. Three silicon diode rectifiers having negative polarity are pressed into the end housing, and three similar diodes having positive polarity are pressed into a die cast aluminum sink. Alternator output is controlled by a voltage regulator (current regulator and cutout relay are not required).

CONTINUED ON NEXT PAGE

CHRYSLER ALTERNATOR ASSEMBLY (EXPLODED VIEW)

CHRYSLER CORP. ALTERNATOR & REGULATOR (Cont.)

SPECIFICATIONS

Performance Data (Cold - 70°)

Alternator	Amperes	Volts	Eng. RPM
2095060	35.0	15.0	1250
2095100	40.0	15.0	1250

Rotation - Clockwise at drive end.

Rated Output - 35 Amps. (2095060), 40 Amps. (2095100).

Field Coil Draw - 2.38 Amps. (min.) to 2.75 Amps. (max.) at 12 volts, with alternator rotor turned manually. 2.97 Amps. (min.) to 3.43 Amps. (max.) at 15 volts with alternator operating at 750 RPM at 70°F.

Rectifier Resistance - 4-10 ohms in forward direction. Infinity in reverse direction.

Capacitor Capacity - .158 microfarad, minimum (internally installed), .5 microfarad (externally installed).

Fuse: 7½ ampere fuse in line between regulator "IGN" terminal and ignition resistor (Regulator No. 1889960), or two fusible wires inside regulator cover (Regulator No. 2095700). *See "Fusible Wire Replacement Note" under VOLTAGE REGULATOR below.*

TROUBLE SHOOTING & DIAGNOSIS

ALTERNATOR DOES NOT CHARGE: Blown fuse or fusible wire. Drive belt loose. Brushes or slip rings worn. Brushes sticking. Field or charging circuits open. Rectifiers open. Stator windings open.

LOW OR UNSTEADY CHARGING RATE: Drive belt loose. High resistance in charging circuit, battery terminals or engine-to-body ground strap. Stator windings open.

LOW OUTPUT & LOW BATTERY: High resistance in charging circuit. Regulator setting too low. Rectifier shorted or open. Stator winding grounded.

EXCESSIVE CHARGING RATE: Regulator setting too high or contacts stuck. Regulator base not grounded. Regulator winding open. Rectifier open.

REGULATOR CONTACTS OXIDIZED: Regulator setting too high or air gap incorrect. Rotor field coil winding shorted.

REGULATOR CONTACTS BURNED: Regulator setting too high. Rotor field coil winding shorted.

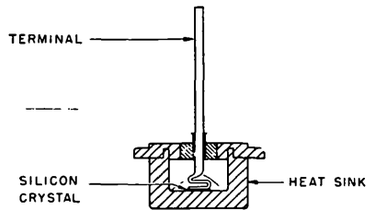
REGULATOR COIL WINDING BURNED: Regulator setting too high.

ALTERNATOR NOISY: Alternator mountings loose. Bearings worn. Drive belt worn. Interference between rotor fan and stator leads or rectifiers. Rotor or rotor fan damaged. Rectifier open or shorted. Stator winding open or shorted.

TESTING

ALTERNATOR IN CAR: With battery fully charged and engine at normal operating temperature, test circuits as follows:

►*CAUTION: Do not ground field circuit between alternator and voltage regulator as regulator will be damaged.*



Charging Circuit Resistance: Disconnect lead at alternator output terminal and connect a 0-50 ampere scale D.C. ammeter in series between output terminal and output lead (lead disconnected from terminal). Connect positive lead of test voltmeter to output lead and connect negative voltmeter lead to battery positive terminal. Operate engine to obtain 10 amps. from alternator. *NOTE - The voltmeter reading should not exceed .2 volt.* If a higher voltage drop is indicated, inspect, clean and tighten all connections in charging circuit.

Current Output: Disconnect battery ground and disconnect alternator output lead at terminal on alternator. Connect a 0-75 ampere scale D.C. ammeter in series between alternator output terminal and output lead .Connect positive lead of test voltmeter to output lead and connect negative lead of test voltmeter to ground. Disconnect field lead at alternator and at regulator, then connect a jumper wire from alternator field terminal to alternator output terminal. Connect engine tachometer and connect battery ground cable. Connect a battery-starter tester (with variable carbon pile) to battery terminals. Operate engine at 1250 RPM, then adjust carbon pile to obtain a reading of 15 volts on test voltmeter. Current output as indicated on test ammeter should be within specifications (see Performance Data above). If output is slightly less than specified, it may be an indication of possible "open" rectifier or other alternator internal condition. If output is considerably lower, it may be an indication of a possible shorted rectifier.

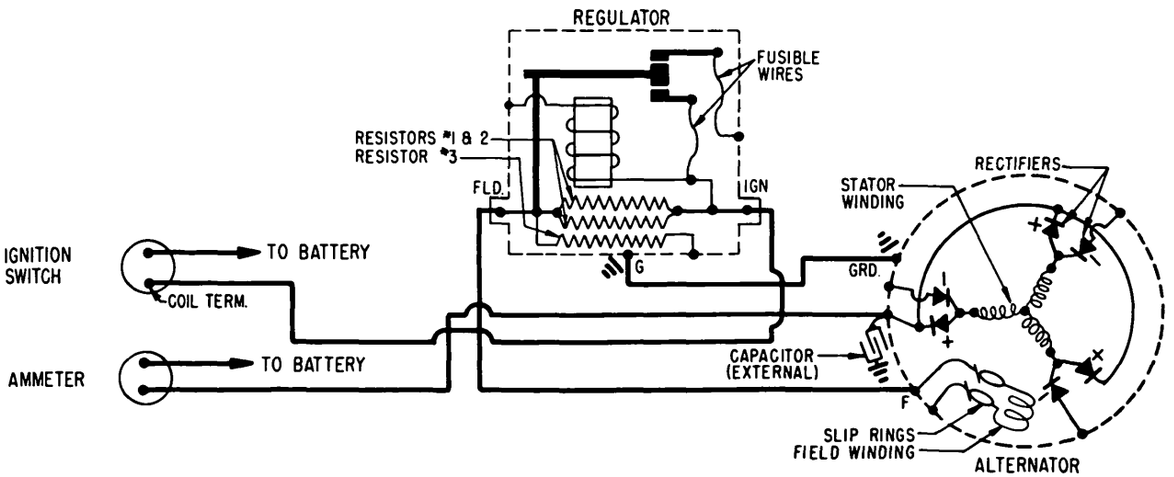
Field Coil Draw: With ammeter connected in circuit as for "Current Output" above, stop engine and note the reverse current reading on ammeter, and battery voltage reading on voltmeter. The rotor field coil should draw 2.38 to 2.75 amperes at 12 volts. A low field coil draw is an indication of high resistance in field coil circuit which may be caused by brushes, slip ring, or field coil connections. A high rotor field coil draw indicates a possible shorted coil.

ALTERNATOR ON BENCH: Field Coil Draw - Connect a source of 12 volt D.C. current and a test ammeter in series to field terminal and to ground. Slowly rotate alternator rotor by hand. The test ammeter reading should be 2.38 to 2.75 amperes at 12 volts.

Rectifier (Diode) Test: Rectifiers may be tested with a test lamp or with Tester Tool C-3829 as follows: *NOTE - The usual cause of an open or blown rectifier is a defective capacitor or a battery installed with reversed polarity. If battery is installed correctly and rectifiers are open, test capacitor capacity.*

TYPICAL RECTIFIER (DIODE)

Test Lamp Method - Disassemble alternator and separate wires at "Y" connector of stator. Use a test lamp with a No. 67 (4 cp.) bulb and a 12-volt battery. Test each rectifier in turn as follows: Touch outer case of rectifier with one probe and wire in center of rectifier with other probe. Reverse the probes, moving the probe from outer case to rectifier wire and the probe at rectifier wire to outer case. If lamp lights in **one** direction, the rectifier is good. If lamp **does not** light in either direction, the rectifier is open. If lamp lights in **both** directions, the rectifier is shorted.



Tester Tool C-3829 Method - Remove brushes and alternator through bolts and separate rectifier end housing and stator from drive end housing and rotor.

Positive Rectifiers - With stator assembly on an insulated surface, connect tool test lead clip to alternator "BAT" (output) terminal and plug tool into 110-volt A.C. power supply. Touch probe to **bare wire connection** of each rectifier. *CAUTION* - DO NOT break sealing around rectifier lead wire or on inner end of rectifier (will accelerate corrosion).

Negative Rectifiers - Connect tool test lead clip to rectifier end housing and touch bare wire connection of each rectifier with probe.

Test Results - Good rectifiers will produce a reading of 2 amperes or more and will be approximately the

CONTINUED ON NEXT PAGE

CHRYSLER CORP. ALTERNATOR & REGULATOR INTERNAL WIRING DIAGRAM

CHRYSLER CORP. ALTERNATOR & REGULATOR (C nt.)

same for the three rectifiers tested If two rectifiers are good and one is shorted, the reading on the good rectifiers will be low and the shorted one will be zero (with bad rectifier disconnected, reading on other two will be satisfactory) If one rectifier is open, its reading will be approximately 1 ampere and the other two rectifiers will show a satisfactory reading Positive and negative rectifiers will read on opposite side of scale on tool

►*RECTIFIER RESISTANCE NOTE* A rectifier should have 4-10 ohms resistance in forward direction and infinite resistance in reverse direction Replace rectifiers with more than 10 ohms resistance in forward direction

Stator Test: Test stator for grounds with a 110-volt test lamp *Insulate stator from rectifier end housing* With one probe of test lamp on stator pole frame, touch each of the stator leads with other probe If lamp lights, stator windings are grounded To test windings for continuity, touch one lamp probe to **all three** stator leads at "Y" connection and other probe to each of three stator leads (disconnected from rectifiers) If lamp does **not** light at each of the three rectifier leads, stator winding is open

OVERHAUL

►*AIR CONDITIONED CAR PULLEY REMOVAL NOTE* Double sheave pulley on air conditioned cars is smaller in diameter and requires use of modified puller blocks SP-3002 (part of Puller C-3615)

►*ALTERNATOR BEARING LUBRICATION & REPLACEMENT CAUTION·* Alternator front and rear bearings are lubricated for life If bearings become dry, install new bearings *DO NOT attempt to lubricate NOTE -* When replacing front bearing, use only Part No 2095653 which has a protective shield and install bearing with shielded side toward rotor

►*RECTIFIER (DIODE) INSTALLATION CAUTION & TOOL MODIFICATION NOTE* Design of rectifier has been changed which requires a modification to Rectifier Installing Tool C-3772 to prevent damage to rectifier seal or core To modify Increase diameter of hole in driving end of tool from 3/8" to 515"(33/64") and increase depth to 1¼" *DO NOT use smaller diameter (unmodified) tool on later design rectifiers*

DISASSEMBLY: Remove insulated brush holder retaining screw, flat washer, nylon washer, and field terminal and carefully lift plastic brush holder (with spring and brush assembly) from end housing Remove retaining screw from ground brush holder, then lift clip, spring and brush assembly from end housing Remove through bolts and pry between stator and drive end housing with a thin blade screwdriver *CAUTION - Stator is laminated, do not burr stator or end housing* Carefully separate drive end housing, pulley and rotor assembly from stator and rectifier housing assembly Remove three nuts and washers and while supporting the end frame, tap rotor shaft with a plastic hammer and separate rotor and end housing To remove drive end bearing from rotor shaft, use Tool C-3615 and adapters C-3375 *CAUTION - Make sure lower end of adapters are equally spaced under the bearing and that tool sleeve is bottomed on bearing* Remove DC output terminal nuts and washers, terminal screw (and inside capacitor, if so equipped) If necessary, heat sink and insulator can be removed To remove rectifiers from heat sink or end housing, cut rectifier wire at point of crimp, then support rectifier housing on Tool C-3771 *NOTE - This tool is cutaway and slotted to fit over wires and around bosses in housing.* Make sure that bore of tool completely surrounds rectifier, then press rectifier out of housing with Tool SP-3380 To remove roller bearing in end housing, support housing with Tool SP-3383, then press bearing out with Tool C-3770

REASSEMBLY: Support heat sink or rectifier end housing on circular plate, Tool SP-3377 Check rectifier identification to make sure correct rectifier is being used *NOTE - Identifying part numbers are stamped on case of rectifier Rectifiers are also identified by paint marks Red for positive and black for negative* Start new rectifier in casting squarely and press in with Tool C-3772 (see note) Crimp rectifier wires to wires disconnected at removal Repeat as necessary for other rectifiers in either the end housing or heat sink Support end housing on Tool SP-3383 so that notch in support tool will clear raised section of heat sink and press bearing into position with Tool SP-3381 *NOTE - Bearings are prelubricated and additional lubrication is not required* Insert drive end bearing in drive end housing and install bearing plate, washer and nuts to hold bearing in position Position bearing and drive end housing on rotor shaft and while supporting base of rotor shaft, press bearing and housing in position on rotor shaft with arbor press and Tool C-3769 *CAUTION - Make sure bearing is installed squarely Bearing must be pressed on shaft until it contacts shoulder on shaft* Install pulley on rotor shaft (support rotor so that all pressing force is on pulley hub and rotor shaft), then press into position with an arbor press *CAUTION - Do not use a force greater than 6,800 lbs* Pulley should just contact bearing inner race Install the heat sink and insulator, then install output terminal screw, insulating washers lockwashers, and nuts *NOTE - Some alternators have the capacitor mounted internally On these units, the capacitor is mounted on top of the heat sink insulator and is held in position with the terminal screw* Make sure heat sink and insulator are in position and tighten the locknut Position the stator on rectifier end housing *CAUTION - Make sure all of the rectifier connectors and phase leads do not interfere with rotor fans and that the capacitor (internal) lead has clearance* Position rotor assembly in rectifier end housing and align the through bolt holes in stator, rectifier end housing and drive end housing Enter stator shaft in rectifier end housing, compress stator and both end housings manually and install through bolts, washers, and nuts Install insulated brush and terminal attaching screw, then install ground brush and attaching screw Rotate pulley slowly to be sure that fans do not hit rectifier and stator connectors

VOLTAGE REGULATOR

CHRYSLER	Chrysler No.
Imperial & 300F	1889960
VALIANT	
Early Cars	① 1889960
Later Cars	② 2095700

① - With "In-Line" fuse
② - With fusible wire in regulator

►*EXCESSIVE AMMETER FLUCTUATION CORRECTION* This condition usually indicated by excessive ammeter pointer flutter, headlight flicker and heater blower motor speed variations at steady engine speeds, and may be caused by high resistance in field circuit to alternator or voltage regulator improperly set For proper diagnosis and correction, proceed as follows Run engine at various steady speeds with heavy electrical load (headlights and accessories on) to determine degree of fluctuation Stop engine, disconnect lead at "IGN" terminal of regulator and install a jumper wire from "IGN" terminal to positive terminal of battery Operate engine at 1250 RPM and observe flutter

1) If ammeter is normal, trouble is corrosion or other high resistance in field circuit connectors Clean and tighten all connections *NOTE -* On cars with 7½ ampere fuse in circuit, clean fuse and holder terminals and tape fuse holder to prevent dirt and moisture entry

2) If jumper wire did not correct the trouble or if ammeter fluctuation is excessive regardless of engine speed or electrical load, remove voltage regulator from car and solder a piece of copper wire between 38 ohm resistor terminal connected to "IGN" terminal of regulator and regulator base *CAUTION -* Use only rosin core solder and be sure regulator base is heated enough for proper metal fusion

3) Install regulator and adjust according to procedures and specifications below

►*REGULATOR 2095700 FUSIBLE WIRE REPLACEMENT NOTE* To replace fusible wire, proceed as follows Cut blown wire from connection at rivet in regulator base (do not unsolder as voltage coil wire may be damaged), and unwind wire from regulator contact bracket Use rosin core solder only, tin one end of Fusible Wire No 2275242 and hold wire in recess in rivet against old fuse wire Put a drop of solder on wires When cool, pull fusible wire up and wrap around contact bracket and solder wire to bracket to be sure of a good connection

DESCRIPTION: Field control type Temperature compensated, vibrating type voltage regulator with two sets of contacts using a common armature On Regulator 2095700, upper stationary contact bracket is connected to "IGN" terminal by a fusible wire, and lower stationary contact bracket connected to ground by another fusible wire (Regulator 1889960 has 7½ ampere fuse in line between "IGN" terminal and ignition resistor instead of fusible wires) Regulator operates on either upper or lower contacts (both sets never in operation at same time) depending on load and battery requirements as follows

Upper Contact Operation (Low Speed & High Load) - Armature travel opens and closes upper contacts, cutting regulator resistance in and out of field circuit, and limiting alternator field current

CONTINUED ON NEXT PAGE

CHRYSLER CORP. ALTERNATOR & REGULATOR (C nt.)

Low r Contact Op rati n (High Speed & Low Load). Armature travel opens and closes lower contacts, grounding the regulator field terminal and bypassing alternator field coil (contacts closed), or cutting resistance in field (contacts open), and limiting field current

CHECKING REGULATOR: Connect an ammeter in series with alternator output terminal (BAT) and the wire disconnected from alternator DC output terminal Connect a DC voltmeter positive lead to alternator output terminal and ground the voltmeter negative lead to alternator frame or regulator base Start engine and adjust engine speed to 1250 RPM *NOTE - No reading on ammeter indicates blown fuse or fusible wire in regulator* Turn on lights and electrical accessories to create enough electrical load that 15 minutes operation will stabilize the regulator temperature Adjust electrical load so that there will be 15 amperes flowing in circuit with a fully charged battery Voltmeter reading should be as indicated in the following table for the ambient temperature in which the regulator is operating

►*AMBIENT TEMPERATURE NOTE The ambient temperature is the temperature registered on a reliable thermometer positioned 2" from regulator cover*

Voltage Setting - Ambient Temp.

Temp. (°F)	ℂ Voltage	Temp. (°F)	ℂ Voltage
0°	14 0-14 6	95°	13 6-14 2
25°	13 9-14 5	118°	13 5-14 1
48°	13 8-14 4	140°	13 4-14 0
70°	13 7-14 3		

ℂ - There will be a slightly higher voltage at higher engine speeds, however, this must not exceed 7 volts at any temperature range

ADJUSTMENT: V ltag - Adjust voltage by bending lower spring hanger of regulator **down** to increase voltage, up to decrease voltage *CAUTION - Do not short circuit between spring hanger and base or spring Use an insulated bending tool*

Armature Air Gap: 048- 052" Check air gap with test lamp connected between ignition and field terminals on regulator Insert a 048" wire gauge between armature and magnet core at hanger side of nylon stops Press armature plate down Upper contacts should open and test lamp should go dim Insert a 052" wire gauge in the same position and depress armature Upper contacts should remain closed and test lamp should remain bright To adjust, bend upper contact support (1889960), loosen contact bracket attaching screw and adjust contact bracket (2095700)

Lower Contact Clearance: 015"± 001" with armature pressed down so armature rests on nylon stop To adjust, bend lower contact arm *NOTE - Press down on armature and not on contact spring*

DELCO-REMY ALTERNATOR (EXTERNAL RECTIFIER) & REGULATOR

► CAUTIONS

►*BATTERY INSTALLATION, BATTERY CHARGING, OR USING ABOOSTEP BATTERY TO START ENGINE CAUTION R versed polarity or excessive voltage will result in extensiv damage to alternator system. NOTE THE FOLLOWING TO PREVENT DAMAGE*

Battery Installati n - Alternator polarity determines which battery terminal is grounded For negative polarity alternators, **negative** battery terminal must be grounded *DO NOT REVERSE BATTERY LEADS or rectifier assembly will be damaged*

Charging Battery - If a "Fast Charger" is used, both of the car battery cables must be disconnected from battery *DO NOT use a "Fast Charger" to provide starting voltage*

Bo ster Batt ry (Us d To Start Engine) - Booster battery must be connected with negative lead to negative terminal of battery and positive lead to positive terminal of battery *DO NOT REVERSE BATTERY LEADS.*

DESCRIPTION: Main alternator components are the stator, rotor, brushes, slip rings, slip ring end housing and drive end housing Rectifier assembly is an externally mounted dry plate type which is connected to the three output terminals of the alternator Alternator voltage and field circuit is controlled by a voltage regulator unit (see "Voltage Regulator" below for further description) *NOTE - Alternators may be either "A" circuit or "B" circuit types Data below applies to "A" circuit types only*

Stat r - Consists of an iron core with three phase windings electrically 120° apart wound in slots around inside circumference and forming the alternator frame Stator leads are connected to terminal posts in slip ring end housing and these leads are connected to the external rectifier assembly by additional leads

Rot r - Consists of a single field coil encased between two six-fingered overlapping iron sections assembled on a shaft Some field coils contain a main field winding and a reverse high resistance shunt winding connected in parallel to the main winding to insure positive voltage control at high speeds Other field coils have a single main winding only Field coil leads are connected to three slip rings (two rings for main winding, one ring for reverse winding) which are insulated from each other and from the shaft Battery is connected to field coil through brushes and the slip rings *NOTE - Some alternators have a "double" rotor which has two main field windings and two reverse field windings*

Slip Ring End Housing - Supports rotor shaft rear ball bearing, brush holders and brushes, and all terminals for lead connections

Drive End Housing - Supports rotor shaft front ball bearing, pulley fan, and pulley Through bolts hold entire assembly together

Rectifier - Dry plate, three phase, full wave, bridge type, selenium rectifier mounted separately from alternator and connected to it by three leads from stator phase windings Two output terminals are mounted on rectifier to connect to car wiring

TESTING & TROUBLE SHOOTING

►*CAUTION.* **1)** *Do not ground alternator output terminal or alternator and circuit will be damaged*
2) *Do not polarize alternator as it is not required and doing so will damage entire system*
3) *Before making test connections, ignition switch must be off*

Current Output Test: With alternator, rectifier, regulator, and battery connected in the usual manner, check current output with an ammeter *See "Specifications" above NOTE* - Specifications apply to alternator when operating with full field current determined only by the resistance of main field winding

Rectifier Test: Clean gently between rectifier plates to remove dirt, using *care not to damage painted surfaces* Test as follows Connect an ammeter and a 1 ohm fixed resistor (75 ampere capacity) in series across output side of rectifier Connect a battery and carbon pile rheostat with all resistance turned in across two of the input terminals Adjust rheostat to test voltage shown in "Voltage & Current Specification Table" below and note the current reading *NOTE - Make checks quickly (within 15 seconds) to avoid overheating rectifier* Repeat test for each of six tests (A through F) as shown in "Test Connection Table", below, reversing ammeter connections to obtain current reading Replace rectifier if current reading not within specifications *CAUTION - DO NOT apply more voltage than specified to input terminals as excessive current draw resulting from higher voltage will burn out rectifier*

►*RECTIFIER TERMINAL NUMBERING NOTE* In the following table, rectifier input terminals are numbered

B	No. 2	No. 1
C	No. 1	No. 3
D	No. 3	No. 1
E	No. 2	No. 3
F	No. 3	No. 2

Voltage & Current Specification Table

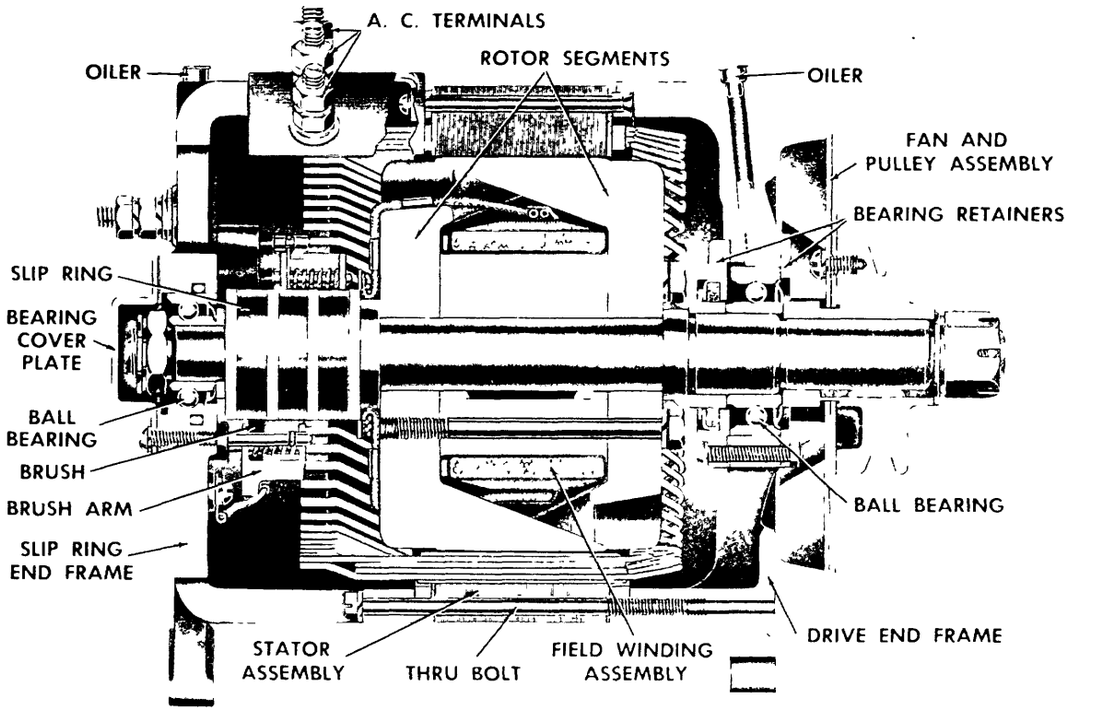
Rectifier	Test Volts	Min. Current	Max. Variation
1924332	5.75	29.5 amps.	6 amps.
1926291	5.0	16.0 amps.	3.5 amps.
1930086	5.75	29.5 amps.	6 amps.
1930522	11.5	30.5 amps.	5 amps.
1932630	5.75	19.8 amps.	8 amps.
1934404	5.75	24.0 amps.	6.5 amps.

HIGH CHARGING RATE TO FULLY CHARGED BATTERY: Voltage regulator setting too high or regulator faulty. Overheated battery. Alternator field circuit grounded in alternator, regulator, or wiring.

Checking - If battery not overheated, operate alternator at idle speed or a speed to give 30 amperes charge, whichever is higher, and disconnect lead from regulator "F" terminal. If output drops, regulator is faulty. If output remains high, disconnect field circuit at alternator. If output drops, wiring is grounded. If output remains high, field circuit is grounded in alternator.

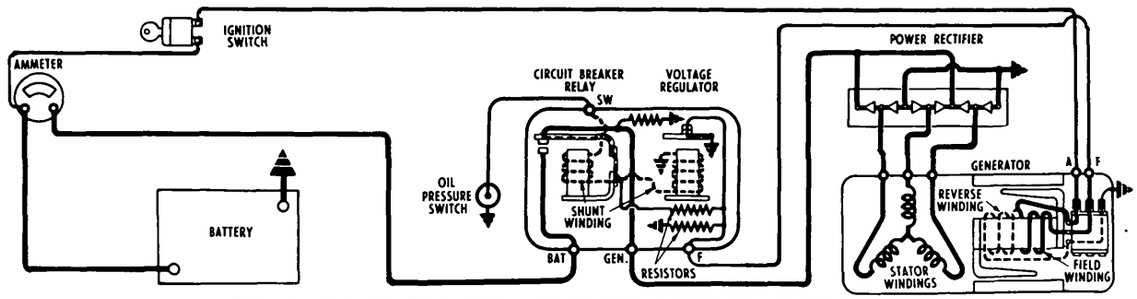
►*REVERSE WINDING NOTE:* If reverse field winding is open, high charging rate to fully charged battery will be present at high speeds even though all other parts of the system function properly.

LOW CHARGING RATE & LOW BATTERY: Wiring damaged or has high resistance. Faulty battery. Drive belt loose. Alternator or regulator faulty.



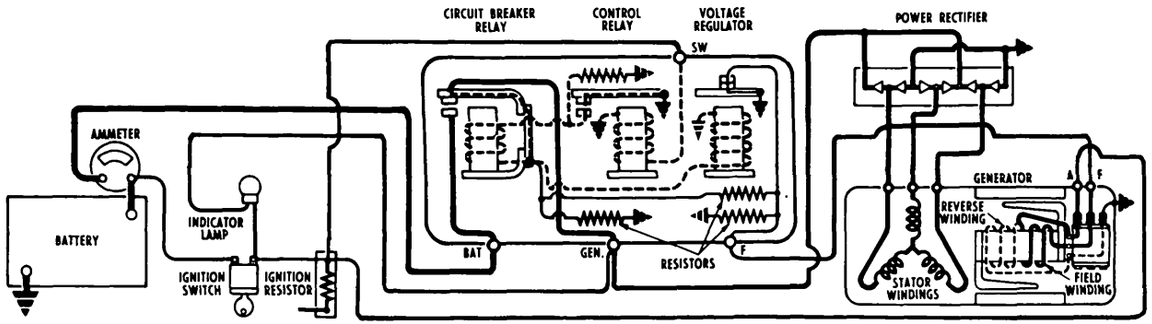
Checking - If wiring, battery, and drive belt are satisfactory, operate alternator at idle speed or a speed to give 30 amperes charge, whichever is higher, turn on a 30 ampere load and momentarily ground "F" terminal of regulator. If output does not increase to approximately 30 amperes, alternator is faulty. If output increases with "F" terminal of regulator grounded, regulator setting is too low or points are oxidized.

LOW BATTERY & NO CHARGING RATE: Wiring damaged or has high resistance. Battery faulty. Rectifier faulty. Alternator or regulator faulty.



Checking - If wiring and battery are satisfactory, proceed as follows: 1) Operate alternator at idle speed or a speed to give 30 amperes charge, whichever is higher, and measure output voltage at rectifier. If voltage sufficient to charge battery, alternator and rectifier are good.

2) Oil Pressur Switch C ntrol-Type Circuit - Check oil pressure switch by connecting a jumper wire from



CONTINUED ON NEXT PAGE

TYPICAL DELCO-REMY ALTERNATOR (SECTIONAL VIEW)

DELCO-REMY ALTERNATOR & 2-UNIT REGULATOR WIRING DIAGRAM

DELCO-REMY ALTERNATOR & 3-UNIT REGULATOR WIRING DIAGRAM

DELCO-REMY ALTERNATOR (EXTERNAL RECTIFIER) & REGULATOR (Cont.)

"SW" terminal of regulator to ground. If alternator charges, replace oil pressure switch. If oil pressure switch good, circuit breaker relay in regulator is faulty.

3) **Regulator Control Relay Type Circuit** - If control relay contacts are closed but circuit breaker relay contacts are open circuit breaker relay winding is open. If control relay contacts do not close, control relay winding is open. If both control relay and circuit breaker relay contacts are closed, there is an open series circuit in regulator.

4) Check field current draw by disconnecting rectifier from alternator, operating alternator at idle speed and connecting a low reading ammeter in series with the field circuit at regulator "F" terminal If field current less than specified (see "Specifications" above), ground regulator "F" terminal and recheck. If field current remains low, alternator field circuit is faulty. If field current increases to specifications, regulator has an open field circuit or oxidized contact points.

5) If field current normal, check stator winding voltages at alternator output terminals with rectifier disconnected from alternator. If voltages vary more than .2 volt, stator windings are shorted If stator windings are satisfactory, reconnect rectifier and recheck. If voltages vary more than 1 volt with a charge rate of 30 amperes, rectifier is faulty (see "Rectifier Test" above). If voltages vary less than 1 volt with rectifier connected, regulator has a low voltage setting.

EXCESSIVE REGULATOR CONTACT POINT ARCING: Regulator resistors open. Alternator main field winding shorted.

OVERHAUL

Disassembly: Remove through bolts and separate end housings from stator. Remove rotor from stator Use a gear puller or arbor press to remove bearings from end housings or rotor shaft. For rotor disassembly, see "Field Coil Replacement" below.

Bearings: Replace bearings if worn or defective.

Brushes: Brushes should be a free fit in holders. Replace brushes if worn to less than ½ original length (compare with new brushes) Check brush spring tension (see "Specifications" above) and bend spring as required.

Slip Rings: If rough or out-of-round, slip rings can be trued in a lathe **if outside diameter is never reduced below 1.560".** If slip rings cannot be trued to maintain minimum diameter, replace as follows Remove glass twine between slip ring assembly and rotor segment and unsolder leads. Pull slip ring assembly from shaft with a gear puller. *Note position of leads in relation to tab to which connected. DO NOT shorten leads* Clean shaft and rotor segment surfaces in contact with slip rings of varnish to assure proper fit of new assembly. Press new assembly on shaft, using keyway as a guide Solder field leads, using rosin flux, wrap several layers of glass or cotton twine between tabs and rotor, and coat twine with glyptol or varnish. Turn slip rings in a lathe to 1 625" diameter and polish smooth with No. 00 sandpaper

Stator: Use a 110-volt test lamp and check for circuit between each stator terminal and frame. If lamp lights, stator winding is grounded. Check circuit between each two stator terminals. If lamp does not light, stator winding is open. To test for short circuited stator, see step 5) under LOW BATTERY & NO CHARGING RATE above.

Rotor: Use a 110-volt test lamp and check rotor field windings for ground by connecting test lamp between each slip ring and rotor shaft or segments. If lamp lights, reverse or main field winding is grounded. Check for open field winding by connecting test lamp between each two slip rings. If lamp does not light when connected to any two slip rings, a field winding is open. To check for shorted field windings, check field current draw (see "Specifications" above) by connecting voltmeter to both slip rings. If rotor has also a reverse field winding, connect voltmeter as follows Number slip rings with other ring as No. 1, middle ring No 2, and ring nearest rotor segment No. 3. To check main field, connect rings No. 2 & 3. To check reverse field, connect rings No 1 & 3 If current draw is more than specified, a winding is shorted. *CAUTION - To insure accurate measurement, connect voltage source directly to slip rings.*

Field Coil Replacement - Disassemble rotor assembly by removing slip ring assembly, pressing rotor shaft out with an arbor press, and removing through bolts holding rotor segments together. Note relative position of parts for reassembly. *CAUTION - Use a soft hammer only if necessary to tap parts loose* Wash all metal parts in caustic solution to remove varnish At reassembly, be sure that rubber washer fits **around** rotor core After reassembly, dip rotor assembly in a modified phenolic varnish and bake to prevent movement of winding in any direction.

Reassembly: Reverse disassembly procedure, installing all parts in proper order Hold brushes away from slip rings to prevent damage when installing rotor When pressing fan and pulley on shaft, support shaft, not end housing to prevent brush damage.

VOLTAGE REGULATOR

DESCRIPTION: Two and three unit types used **Two unit type** has a voltage regulator of conventional design and a circuit breaker relay to control the D C current between the rectifier and battery. Circuit breaker relay is operated by D.C. voltage from rectifier when engine oil pressure switch completes circuit to ground. **Three unit types** have same type voltage regulator and circuit breaker relay as two unit type, and in addition, a circuit breaker control relay which closes and opens the ground circuit of circuit breaker relay when ignition switch is turned on or off.

SPECIFICATIONS

Voltage Regulator

Normal Setting - 13 8-14.8 volts at 125°F ambient temperature

Air Gap - 075" with armature pressed down until contacts just touch

Circuit Breaker Relay

Closing Voltage - 7.5-10 5 volts (1119159, 160), 7.5-9 5 volts (Others).

Contact Gap - .027" (1119159, 160), .032" (Others) with armature against upper armature stop.

Air Gap - 013" (1119159, 160), .017" (Others) with armature pressed down until contacts just touch

Control Relay

Closing Voltage - 7.5-10.5 volts.

Contact Gap - .025" with armature against upper armature stop.

Air Gap - .035" with armature pressed down until contacts just touch.

TESTING & TROUBLE SHOOTING: *See "Testing & Trouble Shooting" above.*

ADJUSTMENT

►*ADJUSTMENT CAUTIONS:* 1) Before checking or adjusting, bring regulator to operating temperature of 125°F by connecting a ¼ ohm resistance in series with battery and operating regulator for 15 minutes with cover in place and no other load than ignition until regulator heated and temperature stabilized.

2) Voltage regulator checks must be made at alternator speed of 3000 RPM or at maximum operating speed of alternator, whichever is lower.

3) Alternator must be cycled after each electrical adjustment and before each check reading is made as follows Connect a 25 ohm, 25 watt rheostat in series with field circuit. Reduce voltage below 4 volts by setting variable resistance at maximum, opening circuit to "IGN" or "SW" terminal of regulator by disconnecting lead or turning off ignition, and reconnecting circuit or restarting engine and bringing voltage up by decreasing resistance

ELECTRICAL CHECKS & ADJUSTMENTS: Voltage Regulator - *See "Delco-Remy 1119000, 1119100, 1119200, 1972000 Series Single Contact Regulators" in this section.*

Control Relay: Adjust closing voltage as follows· With "BAT" and "SW" terminal leads disconnected, connect a jumper wire between "GEN" and "SW" terminals, and a voltmeter between "SW" terminal and ground. Connect a 25 phm, 25 watt variable resistor in field circuit at "F" terminal with all resistance turned in. With alternator at idle speed, decrease resistance until contacts close and note voltage reading. Adjust by turning spring adjusting screw Increase spring tension to increase setting Remove jumper lead and reconnect "SW" lead to terminal

Circuit Breaker Relay: Disconnect lead from regulator "BAT" terminal. **On Oil Pressure Switch control,** connect a jumper between "SW" terminal and ground and a voltmeter between "SW" and "GEN" terminals. **On Control Relay control,** connect a voltmeter between "GEN" terminal and regulator base. **On all types** connect a 12-volt lamp between "BAT" terminal and regulator base With a 25 ohm, 25 watt variable resistor in field circuit at "F" terminal and alternator at idle speed, slowly decrease resistance until lamp lights and note voltage. Adjust by turning spring adjusting screw. Increase spring tension to increase setting.

MECHANICAL ADJUSTMENTS: Make adjustments as follows

Air Gap: With armature pressed down until contacts just close, measure gap between armature and core. See *Specifications.* Adjust as follows

Voltage Regulator - Loosen upper contact mounting screws and raise or lower contact as required.

Circuit Breaker Relay - Loosen adjusting screws on back of relay and raise or lower armature as required.

Control Relay - Bend lower contact support.

Contact Gap: Check with armature against upper armature stop and adjust by bending upper armature stop. See *Specifications*

LEECE-NEVILLE ALTERNATOR & REGULATOR

FORD CARS & TRUCKS

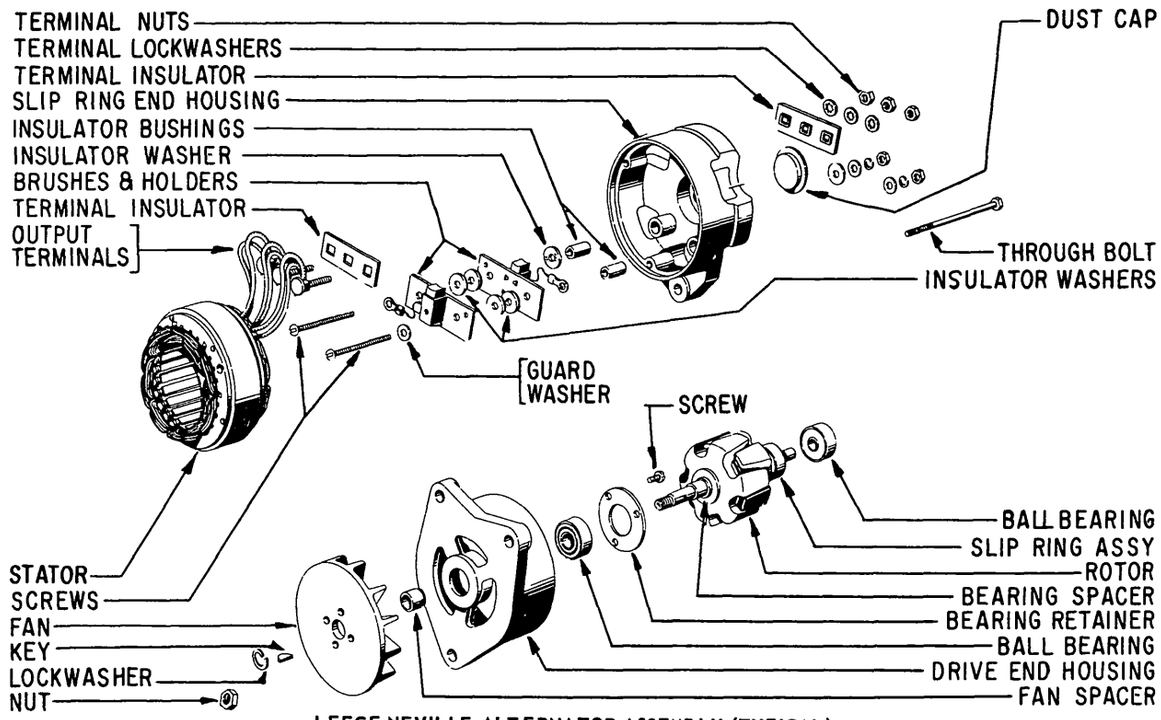
⑥ - May also be marked B9FA-10300-B.
⑦ - External Rectifier No. C0011068-CA (Rambler No 3149242)

►CHANGES, CAUTIONS, CORRECTIONS



►*BATTERY INSTALLATION, BATTERY CHARGING, OR USING A BOOSTER BATTERY TO START ENGINE CAUTION: Reversed polarity or excessive voltage will result in extensive damage to alternator system. NOTE THE FOLLOWING TO PREVENT DAMAGE.*

Battery Installation - Alternator polarity determines which battery terminal is grounded. For negative polarity alternators, **negative** battery terminal must be grounded *DO NOT REVERSE BATTERY LEADS or rectifiers will be damaged.*

Charging Battery - If a "Fast Charger" is used, both of the car's battery cables must be disconnected from battery *DO NOT use a "Fast Charger" to provide starting voltage.*

Booster Battery (Used To Start Engine) - Booster battery **must** be connected with negative lead to negative terminal of battery and positive lead to positive terminal of battery *DO NOT REVERSE BATTERY LEADS.*

DESCRIPTION: Main alternator components are the stator, rotor, brushes, slip rings, slip ring end housing and drive end housing Rectifiers consist of an externally mounted dry plate type on some models or are incorporated in slip ring end housing on other models Alternator voltage and output is controlled by a voltage regulator unit (see "Voltage Regulator" below for further description).

LEECE-NEVILLE ALTERNATOR ASSEMBLY (TYPICAL)

Stator - Consists of an iron core with three phase windings electrically 120° apart wound in slots around inside circumference. Stator leads are connected to terminal posts in slip ring end housing. These leads are connected to the external rectifier assembly or to internal rectifiers by additional leads.

Rotor - Consists of a single field coil encased between two six-fingered overlapping iron sections assembled on a shaft The two ends of field coil are connected to two slip rings insulated from each other and the shaft Battery is connected to field coil through brushes and the slip rings

Slip Ring End Housing - Supports rectifier heat sink (if equipped), rotor shaft rear ball bearing, brush holders and brushes, and all terminals for lead connections.

Drive End Housing - Supports rotor shaft front ball bearing, pulley fan, and pulley. Through bolts hold entire assembly together

Rectifier (External Type) - Assembly is a dry plate, three phase, full wave, bridge type, selenium rectifier mounted separately from alternator and connected to it by three leads from stator phase windings Two output terminals are mounted on rectifier to connect to car wiring

Rectifier (Internal Type) - Six silicone diode rectifiers are screwed into a metal heat sink mounted in slip ring end housing and insulated from it. Three rectifiers have negative polarity and are connected to ground through negative output terminal The other three rectifiers have positive polarity and are connected to alternator positive output terminal.

►*CHARGE INDICATOR LIGHT RECTIFIER NOTE:* On some Ford Light Duty trucks a modification to accommodate the charge indicator light consists in operating the load relay of the voltage regulator from a pair of rectifiers connected across one phase of the stator winding.

SPECIFICATIONS

Performance Data

Alternator	Amperes	Volts	Alt. RPM
30 Amp. (Ford)	30 min.	14.0	①
50 Amp. (Ford)	50 min.	14.0	① 2040
50 Amp (Rambler)③	50	14.0	② 2050
60 Amp. (Ford)	60 min	14.0	① 3400
60 Amp (Rambler)④	60	14 0	⑤ 4400
100 Amp (Ford)	100 min.	14.0	①

① - 1600 Engine RPM. ② - 880 Engine RPM
③ - Alternator No A0015428-GA.
④ - Alternator No. A0012036-AA. ⑤ - 1800 Engine RPM.

Rotation - Clockwise at drive end.
Rated Output - See Application Table above.
Field Coil Draw - 2 4-3.0 amps (Ford), 2 5-3.0 amps. (Rambler) at 12.0 volts.

TESTING

►*CAUTION: 1) Do not ground field circuit between alternator and voltage regulator as regulator will b damaged. 2) Do not ground alternator output terminal or alternator and circuit will be damaged. 3) Do not op rate alternator on open circuit with field winding energized.*

CONTINUED ON NEXT PAGE

LEECE-NEVILLE ALTERNATOR & REGULATOR (C nt.)

4) *Do not polarize alternator as it is not required and doing so will damage entire system*

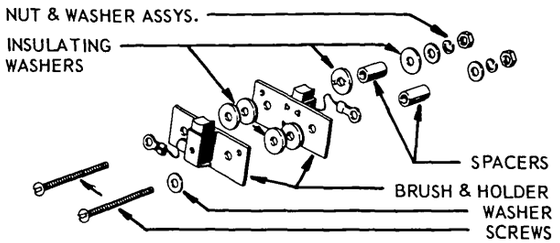
5) *Before making test connections, ignition switch must must be off*

ALTERNATOR IN CAR: With battery fully charged and engine at normal operating temperature, test circuits as follows

Current Output: Disconnect alternator "F" and "G" leads *from regulator and connect leads together* Connect an ammeter positive lead to these two leads, start engine and connect ammeter negative lead to battery positive terminal Operate engine at proper speed *(see "Performance Data" above)* and note ammeter reading Current output should reach or exceed specifications *(see "Performance Data" above)*

►*ALTERNATOR TESTER NOTE* When using an Alternator Tester for an output test, the maximum voltage variation between phases should not exceed 1 5 volts (no load), 3 volt (load)

Field Coil Draw: Disconnect "F" lead from alternator and connect an ammeter negative lead to "F" terminal and positive ammeter lead to battery positive terminal Current draw should be as in specifications If current draw is low or zero, field has high resistance or is open If current draw is high field is shorted or open



ALTERNATOR OFF CAR: Stator Test - *NOTE - This test may be made on alternators with external rectifier with alternator in car if stator leads to rectifier assembly are disconnected On internal rectifier alternators, remove stator from slip ring end housing* Use a 110 or 220-volt test lamp and test probes With one test probe on alternator end housing or stator core, touch other probe to each phase terminal in turn If lamp lights, stator is grounded Check stator windings for continuity with an ohmmeter and test probes at two of the winding leads in turn Each phase should show a low resistance If resistance is high, stator windings are open or shorted

Rotor Test: Test rotor with a 110-volt test lamp There should be no ground between either slip ring or shaft There should be no ground between rotor core and slip rings

Rectifier (External Type) Service: Clean rectifier assembly frequently by blowing compressed air through plates to remove dirt With rectifier removed, use a bottle brush or rag between plates *CAUTION - DO NOT force brush or rag between plates DO NOT use solvent Clean rectifier DRY.* To test rectifier, connect a 25 ampere load across output terminals with an ammeter in circuit Touch test probes from a 12-volt battery to two of the three terminals in turn Ammeter readings should be equal for all three checks A different reading in any one test indicates a faulty rectifier *CAUTION - DO NOT apply voltage to direct current output terminals of rectifier*

Rectifier (Internal Type) Test: *NOTE - Resistance of silicon rectifiers will vary due to temperature, type of ohmmeter, battery voltage used in test equipment, and other factors* Remove slip ring end housing from stator assembly Proceed as follows

Method 1 - Connect ohmmeter leads to the two alternator output terminals Reverse the leads Resistance should be 3 3-20 ohms in one direction and infinite in the other direction

BRUSH & HOLDER ASSEMBLY (EXPLODED)

Method 2 - With positive probe of ohmmeter on alternator negative output terminal, touch each of stator winding terminals with other probe Resistance should be 5-45 ohms Reverse the probes Resistance should be infinite Now place negative probe on alternator positive output terminal and touch each of stator winding terminals with other probe Resistance should be 5-45 ohms Reverse the probes Resistance should be infinite

Rectifier Mount Ground Test (Internal Type Rectifiers): Use a 110-volt test lamp and check from each output terminal screw to ground If ground exists, check top, center, and bottom rectifier assembly-to-housing mounts, and both output terminals

OVERHAUL

►*OVERHAUL NOTE. Alternator need be disassembled only so far as necessary for testing or needed repairs Bearings need be removed only if loose or if lubricant lost On 100 Amp alternator, repair rotor assembly (except for slip rings, bearing, or coil) only if proper machining and balancing equipment available*

DISASSEMBLY: 30, 50, 60 Ampere Alternators - Remove fan and pulley assembly with a gear puller Remove key and fan spacer Remove splash shields and pry out bearing dust cap Insert a brush clip on brush holders to retract brushes Remove nuts, washers and insulator from the three stator phase terminals Remove through bolts and pull slip ring end housing from rotor shaft with a gear puller Remove stator from housing (tap with soft hammer if necessary to loosen) Remove rectifier assembly mounting screws and remove assembly from housing With arbor press or gear puller, press rotor from drive end housing Tap or press bearings out of each housing Remove brush holder assemblies

Slip Ring Replacement - While removing old slip rings, place new slip rings in a warm area to prevent cracking when installing Unsolder coil wires from slip rings Pull rings from shaft with gear puller or use arbor press Press new slip ring assembly on shaft with slots in line with hole in shaft for coil wires and until outer face of outer slip ring is 9/16" from end of shaft Concentricity of slip ring faces with bearing surface of shaft must be within 002" Cut rings on a lathe to correct

Rectifier Cell Replacement (Internal Type) - *CAUTION - Disturb as few connections as possible Metal-to-metal surface of cell and terminal connections have a special treatment to prevent corrosion and electrolysis Same treatment must be applied to a new or replacement cell* Unsolder cell lead, bend down lock tab on inner bracket and remove cell with a wrench *CAUTION - If spacer between inner and outer rectifier mounting bracket comes out, it must be cleaned on both sides before re-installation* Install new cell Tighten to 20-25 inch-lbs , bend lock tab up Solder lead to cell *DO NOT OVERHEAT OR CELL WILL BE DAMAGED*

100 Ampere Alternator: 1) Remove pulley, both brush holder assemblies from brush end housing and nuts, washers and insulators from stator winding terminals Remove brush end housing dust cap, housing bolts and alternator top support Loosen brush end housing with a soft hammer and remove housing and stator assembly from shaft (use gear puller if bearing is tight) Remove stator from housing Pull drive end housing from shaft with a gear puller Remove retainer and bearing from drive end housing

2) Unsolder both field leads from slip rings and press off slip rings with parallel bars *CAUTION - Use care not to crack slip rings during removal If cracked, they must be replaced* Remove bearing and bearing retainer from slip ring end of shaft (save wood wedge from lead slot under bearing) Remove drive end shaft nut and tap off drive end rotor half with a soft hammer Remove key Press other half of rotor from shaft with an arbor press (use a brass rod on end of shaft to protect and lengthen it) Remove rotor coil from hub *CAUTION - Keep rotor halves together to maintain proper balance*

REASSEMBLY: 30, 50. 60 Ampere Alternators - Press bearings into slip ring and drive end housings (apply pressure to outer race only) Press drive end housing and bearing assembly on rotor shaft with shaft on flat plate of arbor press (use pipe so pressure exerted on bearing inner race only) Install brush holder assemblies as shown in illustration Install a holder clip to retract brushes Install stator over rotor and insert through bolts through drive end housing and stator Install rectifier assembly in slip ring end housing Install slip ring housing and rectifier assembly over stator and rotor assembly and press on slip ring end housing with an arbor press Tighten through bolts Install stator terminal insulator, washers, and nuts Remove brush retainer clip There should be 1/16" clearance between alternator fan fins and drive end housing Install pulley and tighten to 40 ft lbs Test assembly for free turning

100 Ampere Alternator: 1) Press slip ring rotor half (with wire clip) on shaft as far as snap ring and press hub on shaft Install coil with leads under wire clip Install key, press drive end rotor half on shaft and install and tighten locknut Paint rotor with red oxide or red Glyptol varnish to secure coil Place coil leads in slot in shaft, press slip ring bearing on shaft (press on inner race only), place wood wedge in slot and install snap ring and insulating washer Press slip rings on shaft one at a time with tapered side toward bearing and wire cutout aligned with slot in shaft Solder coil leads to slip rings

2) Press drive end bearing into housing (press on outer race only) and install bearing retainer With slip ring end of shaft on press plate, press drive end housing assembly on shaft (use pipe so pressure exerted on bearing inner race only) Install stator over rotor and drive end housing so dowel pin in housing mates with stator hole Install insulator over stator leads and press slip ring end housing on shaft (mate dowel pin in housing with hole in stator) Install alternator top support Install insulator, bushings, washers and terminal nuts on terminals Install brush holder assemblies

CONTINUED ON NEXT PAGE

LEECE-NEVILLE ALTERNATOR & REGULATOR (C nt.)

Clearance between alternator fan fins and housing should be 1/16". Torque pulley nut to 40 ft. lbs.

VOLTAGE REGULATOR

FORD CARS & TRUCKS

Regulator - Ford Nos. -	Alternator
B8C-10505-A	B8TZ-10346-A, E
B8Q-10505-A	B8TZ-10346-G, F
PB8M-10316-A	C1TF-10346-B,C,D
B8C-10505-B	①B8TZ-10346-C,D

RAMBLER

Regulator - Leece-Neville Nos. -	Alternator
R0013456-RA②	A0015428-GA
R0013533-RA③④	A0012036-AA

① - When used as 50 Amp. use Regulator No. B8Q-10505 -A.
② - Rambler No. 3156485 ③ - Rambler No. 3159383.
④ - Two Unit type.

DESCRIPTION: Two and three unit types used (see above) Three unit type has load relay, voltage regulator and current regulator. Two unit type used on some alternators with internal rectifiers has load relay and voltage regulator only. Data and specifications below apply to both types except for current regulator data which is not applicable to two unit type Voltage regulator is a double contact type of conventional design Current regulator is also of conventional design Both units perform the same functions as on a DC current generator-regulator system. Load relay has a single core winding and a single set of contacts. Relay is controlled by ignition switch (except Ford Trucks, see below) which, by energizing core winding, closes relay contacts, energizes alternator field circuit, and connects the "G" and "B" terminals of regulator together (completes alternator charging circuits to battery)

►*FORD LIGHT DUTY TRUCK NOTE*· On trucks with charge indicator light, load relay is operated through a pair of rectifiers connected across one phase of stator windings instead of through ignition switch.

SPECIFICATIONS

Load Relay

Closing Voltage - 5.6-6 4 volts (Ford), 6.0-6.4 volts (Rambler)
Contact Gap - 018-.020" with contacts open.
Air Gap - .018-.020" with contacts closed.
Hinge Gap - .005-.007" with contacts closed.

Voltag R gulator

Voltage S tting (M th d 1) - 13.5-14.3 volts.
Voltage Setting (Method 2) - 13 6-13.8 volts (upper contacts), 13.7-13.9 volts (lower contacts), 14 0-14.2 volts (transfer voltage).
Contact Gap - .018- 020" with lower contacts closed.
Air Gap - .035-.043" with lower contacts closed.
Hinge Gap - .018- 020" with lower contacts closed.

Current Regulator

Setting- 28-32 amps. (30 Amp), 48-52 amps. (50 Amp.), 58-62 amps. (60 Amp.), 98-102 amps. (100 Amp.).
Contact Gap - .018-.020" with contacts open.
Air Gap - 032- 038" with contacts open
Hinge Gap - 005-.007" with contacts open.

ADJUSTMENT

CHECKING & ADJUSTING (ON CAR): *NOTE - Regulator is "Temperature Compensated" type Make following checks and adjustments after regulator heated and stabilized (after 30 minutes operation with 10 ampere load).*

Load Relay: Connect a 250 ohm, 25 watt rheostat from battery positive post to "IGN" terminal of regulator, and a voltmeter positive lead to regulator "IGN" terminal with negative lead grounded Turn full resistance into circuit and slowly decrease resistance until relay points close. Closing voltage should be as specified. To adjust, bend armature spring lower hanger down to increase voltage, up to decrease voltage.

Voltage Regulator: Method No. 1 (Fixed Resistance Method) - Connect voltmeter positive lead to regulator "G" terminal and negative lead to battery negative post. Connect ammeter positive lead to "B" terminal of regulator (disconnect battery lead from regulator) and negative lead to battery negative post with 1½ ohm resistor in line between battery and ammeter. Start engine and slowly increase speed to 1600 RPM. Steady voltmeter reading should be as specified. Retest by stopping engine, momentarily turning off ignition and restarting engine To adjust, bend armature spring lower hanger down to increase setting, up to decrease setting

Method No. 2 - *CAUTION - Before setting each voltage in following test sequence, alternator must be stopped and ignition switch turned off.* Connect an ammeter in series with battery lead to regulator and a voltmeter between "B" and "G" regulator terminals Connect a set of earphones (not less than 1000 ohms resistance) to "F" and "G" regulator terminals. Proceed as follows

1) Start engine and slowly increase speed. Listen (with earphones) for start of vibration of regulator contacts and note voltage reading. Regulator is operating on upper contacts If voltage not as specified, bend armature spring lower hanger down to increase, up to decrease

2) Slowly increase speed past vibration on upper contacts and note voltage when vibration stops. Vibration stops immediately before regulator operates on lower contacts This maximum voltage is "Transfer Voltage" and must be as specified Adjust as in 1) above.

3) Increase speed slowly past "transfer voltage" point and note start of vibration on lower contacts If not as specified, adjust air gap by loosening contact block lock screw and turning carrier block cam adjusting screw.

Current Regulator: Method 1 - With test leads connected as in "Voltage Regulator Method No 1 (Fixed Resistance)" test above, connect a carbon pile rheostat across the 1½ ohm fixed resistor With engine at 1600 RPM slowly decrease resistance of carbon pile rheostat until voltmeter reads 12 volts Ammeter will now indicate specified setting for current regulator To adjust, bend armature spring lower hanger down to increase setting, up to decrease setting. Retest voltage regulator setting with all test equipment removed except the voltmeter and with battery in circuit.

Method 2 - Connect a battery starter variable resistance load tester across battery. With alternator turning at 2000 RPM increase resistance. Current regulator should vibrate and hold line current to specifications To adjust, bend armature spring lower hanger up or down as necessary Retest voltage regulator setting (upper contacts) with only voltmeter connected and battery in circuit

ADJUSTMENT (OFF CAR): The following adjustments are made on load relay, voltage regulator, and current regulator in the same manner

Hinge Gap: Set gap between yoke and armature lower hinge spring by loosening and tightening armature lock screw. *See Specifications.*

Air Gap: Gap between armature or armature stop and core is set by holding armature towards core and adjusting stationary contact adjusting screw *See Specifications.*

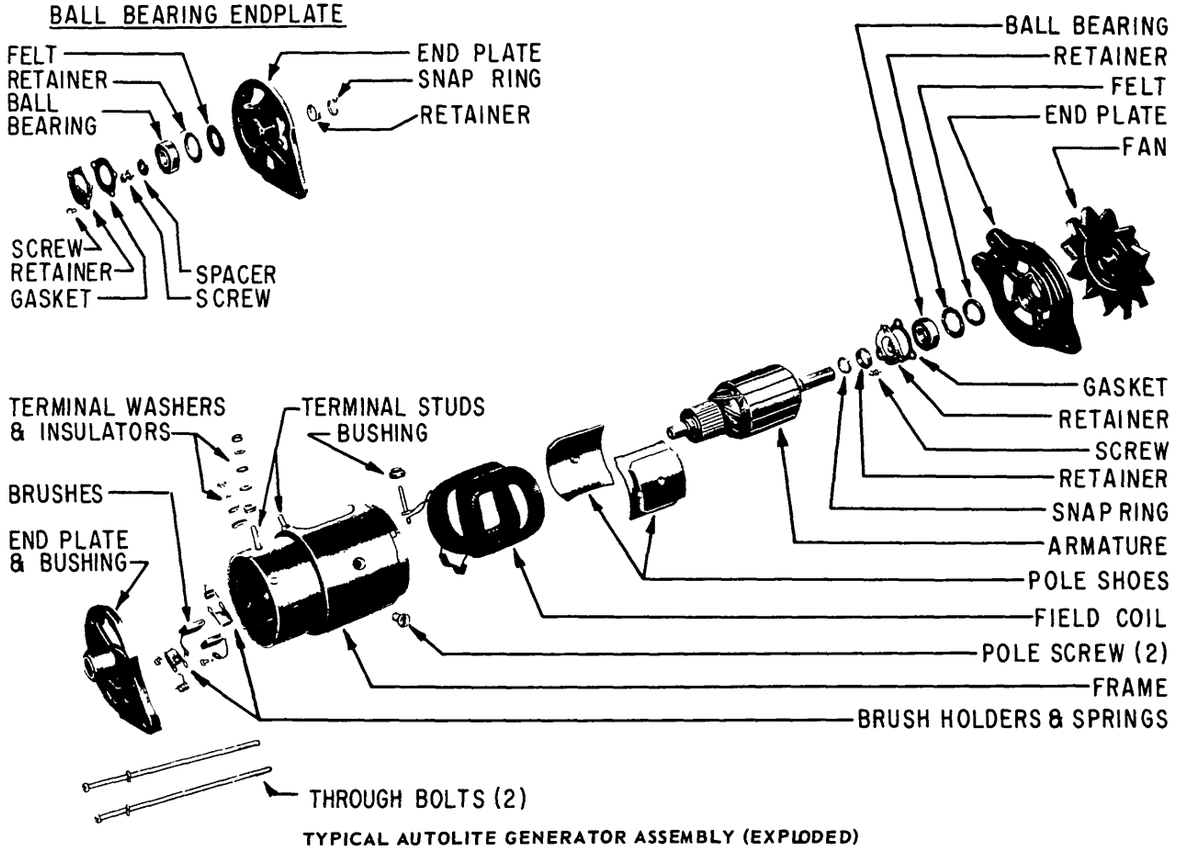
Contact Gap: Set gap by adjusting contact carrier or armature stop *See Specifications.*

Armature Travel: Adjust armature to float within travel limits by bending armature hinge springs (armature spring removed) *NOTE* - On load relay, be sure to solder jumper wire to contact plate

AUTOLITE GENERATORS

DESCRIPTION: Two pole, two brush, shunt generators of conventional design. Generators are force-draft air cooled by a fan built into drive pulley which rotates with armature shaft. Both "A" and "B" circuit types are used. "A" **circuit** generators have field windings connected from insulated brush to generator field terminal, and regulation is accomplished between field terminal, and ground (generator field grounded in regulator). "B" **circuit** generators have field windings connected from generator field terminal to ground brush, and regulation is accomplished between armature and field terminals (generator field grounded in generator). See illustrations.

►*GROUND POLARITY NOTE: Test connections given below are for negative grounded systems. If system is positive grounded, reverse test lead connections.*



TESTING: Current Output - Connect an ammeter between regulator lead and regulator "BAT" terminal. Connect a voltmeter between regulator "ARM" terminal and regulator base. With engine idling, ground regulator field terminal to regulator base with a jumper wire ("A" circuit), connect regulator field and armature terminals together ("B" circuit). Slowly increase generator speed to indicated RPM and note voltmeter and ammeter readings. *See Car Model pages for specifications.* Generator should reach or exceed rated output.

Charging Circuit Resistance: Connect a carbon pile rheostat in series with field lead and "FLD" terminal of regulator. Connect an ammeter in series with battery lead and "BAT" terminal of regulator. Connect a voltmeter from battery positive post to "ARM" terminal of generator. Start engine and adjust accessory load and rheostat to give 20 ampere reading on ammeter. Maximum voltage drop should not exceed 1 volt (.5 volt with ammeter out of circuit).

Ground Circuit Resistance: Leave rheostat and ammeter connected as in "Charging Circuit Resistance" above. Connect voltmeter from negative (grounded) battery post to generator frame. Start engine and adjust accessory load and rheostat to give 20 ampere reading on ammeter. Maximum voltage drop should not exceed .1 volt.

Motoring Test: Remove generator belt. Disconnect all leads from generator terminals. Connect battery to generator armature terminal with an ammeter in circuit. Connect a voltmeter between generator armature terminal and ground. Ground generator field terminal ("A" circuit), connect generator armature and field terminals together with a jumper wire ("B" circuit). Generator should motor at a steady speed. *See Car Model pages for specifications.*

OVERHAUL: Disassembly - Remove commutator cover band (if equipped) and disconnect terminal lead from insulated brush holder. Reach through openings in generator frame or endplate and lift and hook brushes away from commutator. Remove endplate attaching screws or generator through bolts and remove endplate, bearing and brush assembly. *NOTE - Commutator endplates with ball bearing must be pressed from shaft with an arbor press.* Remove armature and drive endplate and bearing assembly. Remove pulley (see Note below). *CAUTION - On generators with pressed on pulleys, remove pulley and bearing from shaft separately as endplate may crack if both units are removed together.* Press armature from endplate and bearing with an arbor press. Remove ball bearings by removing retainers and washers and gently tapping bearing from endplate. Press bronze bushing (if equipped) from commutator endplate.

TYPICAL AUTOLITE GENERATOR ASSEMBLY (EXPLODED)

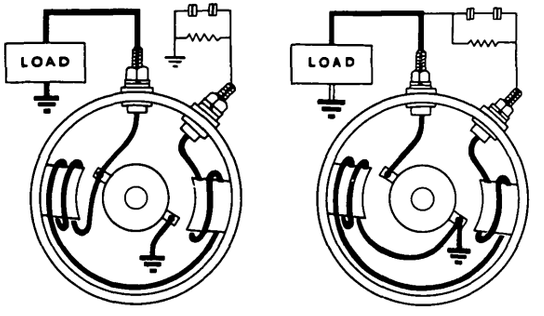
►*PULLEY REMOVAL NOTE:* Pulleys are either bolted and keyed to shaft, or pressed on shaft. Pressed on pulleys can be removed with a suitable puller. Puller, Miller Tool No. C-3615, is recommended for pulley removal.

Inspection - Wipe all parts with a clean cloth. Ball bearings may be cleaned in solvent but **must not** be spun when dried with compressed air. Inspect all parts for wear, roughness, scoring, worn insulation, good solder connections, etc.

Armature: Shaft commutator end runout should not exceed .001". Shaft drive end runout should not exceed .002". Commutator runout with shaft bearing surfaces should not exceed .0005". Reface commutator as necessary, removing only enough metal for smooth surface. Undercut mica segments 1/32" deep with mica square the full width of slot. Polish commutator with No. 00 sandpaper. Check for shorts between armature core and commutator with a 110-volt test lamp. Check armature windings for shorts with a growler.

Field Windings: Check for burned or damaged insulation. Check "ARM" and "FLD" terminal posts for ground with generator frame with 110-volt test lamp ("ARM" and "FLD" terminals should be insulated from frame). make sure field windings are not grounded to frame. Test field current draw as follows: Connect a carbon pile rheostat between battery positive post and "ARM" terminal ("A" circuit), to field coil brush lead ("B" circuit). Connect an ammeter between battery negative post and "FLD" terminal. Connect "ARM" and "FLD" terminals ("A" circuit), field coil brush lead and "FLD" terminal ("B" circuit) with a voltmeter. With rheostat, adjust battery voltage to specified figure and note ammeter reading. Field current draw should be as specified. *See Car Model pages for specifications.* High current reading indicates a short or incorrect coils; low current reading indicates poor connections, high resistance, or incorrect coils. Check for short circuits, high resistance or incorrect coils. *NOTE - When replacing field coils, an impact screwdriver such as C-3475 is recommended to prevent damage to screws and to insure proper tightening. After coils installed and pole screws tightened securely, rap frame sharply with a soft hammer to insure proper seating of pole pieces, then stake pole screws.*

CONTINUED ON NEXT PAGE



AUTOLITE GENERATORS (C nt.)

Brush s: Inspect brushes for freedom in holders and for proper seating. Replace brushes coated with oil or dirt or if worn to less than ½" long. Check brush spring tension. *CAUTION - If brush holders riveted to endplate, check tension with endplate and brushes installed on armature.* With spring scale hooked in hole in end of brush arm or with adapter hooked under arm as near as possible to brush, pull spring scale at right angle to brush and note reading just as arm leaves the brush. *See Car Model pages for specifications. NOTE - If brush holders riveted to generator frame, install new springs when new brushes installed because of difficulty in measuring brush spring tension.* Test brush holders for ground with endplate or frame If brush holder grounded, repair holder or replace endplate or frame (some brush holders riveted to endplate or frame). Seat new brushes for correct fit on commutator with No. 00 sandpaper between commutator and brush and armature rotated in reverse rotation as sandpaper is pulled away. Repeat operation until brushes seat at least 75% over contact surface.

Commutator End Bearing: Inspect bearings for wear, roughness, scoring, etc. Clean ball bearing in solvent DO NOT spin dry. Replace bronze bushing if necessary with a suitable driver. Soak bushing in light oil before installation. Clearance between armature shaft and bearing must not exceed .002". If commutator endplate equipped with ball bearing, pack bearing about ½-full with high temperature, non-fibre ball bearing lubricant before installation. *See "Reassembly" below for ball bearing installation procedure.*

Drive End Bearing: Inspect ball bearing for roughness, pitting, scoring, wear, etc. Clean in solvent, but DO NOT spin dry. For bearing installation, see "Reassembly" below. *CAUTION - On generators with pulley pressed on shaft, drive end bearing is a loose fit bearing because of larger shaft diameter. When bearing pressed on shaft, inner race expands to provide standard ball clearances. DO NOT install the standard ball bearing used on some commutator endplates as binding and bearing failure will result. This special bearing is Autolite No. X-295A and may be identified as follows·*

Bearing Manufacturer	Identification
New Departure	Black Ball Retainer (1 side)
Marlin Rockwell	Black Ball Retainer (1 or 2 sides)
Norma Hoffman	Black Ball Retainer (1 or 2 sides)
Federal	Black Ball Retainer (1 or 2 sides) or 1203/C3 on Inner Race
SKF	SKF-6203-C3 on Outer Race

"A" & "B" CIRCUIT INTERNAL WIRING

Reassembly: Dip drive end bearing felt washer in oil and squeeze to remove excess oil, Assemble felt washer, retainer, ball bearing, gasket & bearing retainer in drive endplate (fill bearing half full with high temperature, non-fibre ball bearing lubricant). Install snap ring on armature shaft with retainer over snap ring. Press drive endplate and bearing assembly on armature shaft. *CAUTION - Support armature so pressure exerted on armature shaft and not on endplate.* Press on inner race of bearing only until bearing inner race is firmly against armature shaft snap ring. For bolted on pulley, install key, pulley and fan assembly and lockwasher and nut. Tighten nut securely For pressed on pulley, support armature shaft only and press pulley on shaft *CAUTION - DO NOT use more than 6800 lbs. pressure to install pulley. Pressure over 7000 lbs. will damage shaft* Install armature and drive endplate assembly into frame assembly and push parts together On commutator endplate with bronze bushing, slide endplate on armature shaft and align dowel pin hole in plate with dowel pin in frame. On commutator endplate with ball bearing, install snap ring on armature shaft with retainer over snap ring Install endplate into position Dip felt washer in oil and squeeze to remove excess oil Install felt washer and retainer. Fill bearing half full with high temperature, non-fibre ball bearing lubricant and press bearing on shaft until inner race of bearing is firmly against snap ring on shaft. *CAUTION - Press on inner race of bearing only and support armature shaft so pressure exerted on shaft only.* On all generators, install through bolts and tighten securely *NOTE - On "B" circuit generators, install through bolts between field lead wire and g nerator frame to prev nt possible field circuit grounding.* Armature shaft endplay on all generators should be 003- 010" Install cover band. Saturate oiler wick with 8-10 drops of light oil

POLARIZING GENERATOR: *Before operating, generator must be polarized as follows*

"A" Circuit - MOMENTARILY touch a jumper wire between regulator "BAT" terminal and regulator or generator "ARM" terminal

"B" Circuit - Disconnect field lead from regulator and MOMENTARILY flash this disconnected field lead to "BAT" terminal of regulator

DELCO-REMY "EXTRUDED FRAME" GENERATORS

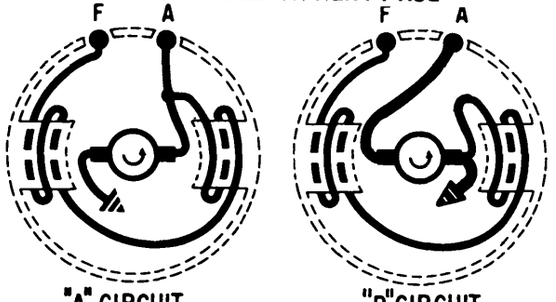
DESCRIPTION: Two pole, two brush, shunt generators of "extruded frame" type design. In this design, commutator end of frame is smaller in diameter than drive than drive end and no cover band is used as there are no inspection openings in the frame. Generators are force-draft air cooled by a fan built into drive pulley which rotates with armature shaft. "A" circuit generators with field grounded through the regulator are the more common type found, however "B" circuit generators with field grounded internally in the generator may also be found on some applications. Data below applies to both type circuits as indicated.

NOTE - Some generators may be of conventional design with cover band around inspection openings in frame. Data below applies to this type also.

LUBRICATION: Hinge oilers should be filled with oil at each lubrication period. If no oilers are provided, repack bearings each time brushes are serviced. *Avoid over-lubrication.*

►*CHARGING CIRCUIT FUSE CAUTION:* Some regulators have a charging circuit fuse clipped to "BAT" terminal of generator regulator. Check for blown fuse and cause of fuse failure when diagnosing generator, regulator, or battery failure. When making test connections, connect test equipment to fuse (do not bypass fuse)

►*GENERATOR FIELD GROUNDING CAUTION: On generators equipped with Double Contact regulators, DO NOT ground generator field with field lead connected to regulator as regulator upper contacts will be burned out instantly.*



►*GRCUND POLARITY NOTE: Test connections given below are for negative grounded systems. If system is positive grounded, reverse test lead connections.*

TESTING: Current Output ("A" Circuit) - Disconnect and ground field lead from "FLD" terminal of regulator. Connect an ammeter in series with battery lead and "BAT" terminal of regulator. Start engine, slowly increase speed to indicated RPM and note ammeter reading Generator should reach or exceed rated output. *See Car Model pages for specifications.*

Charging Circuit Resistance ("A" Circuit): Connect a carbon pile rheostat in series with field lead and "FLD" terminal of regulator. Connect an ammeter in series with battery lead and "BAT" terminal of regulator. Connect a voltmeter from battery positive post to "ARM" terminal of generator. Start engine and adjust accessory load and rheostat to give 20 ampere reading on ammeter Maximum voltage drop should not exceed 8 volt (including .25 volt drop across test ammeter).

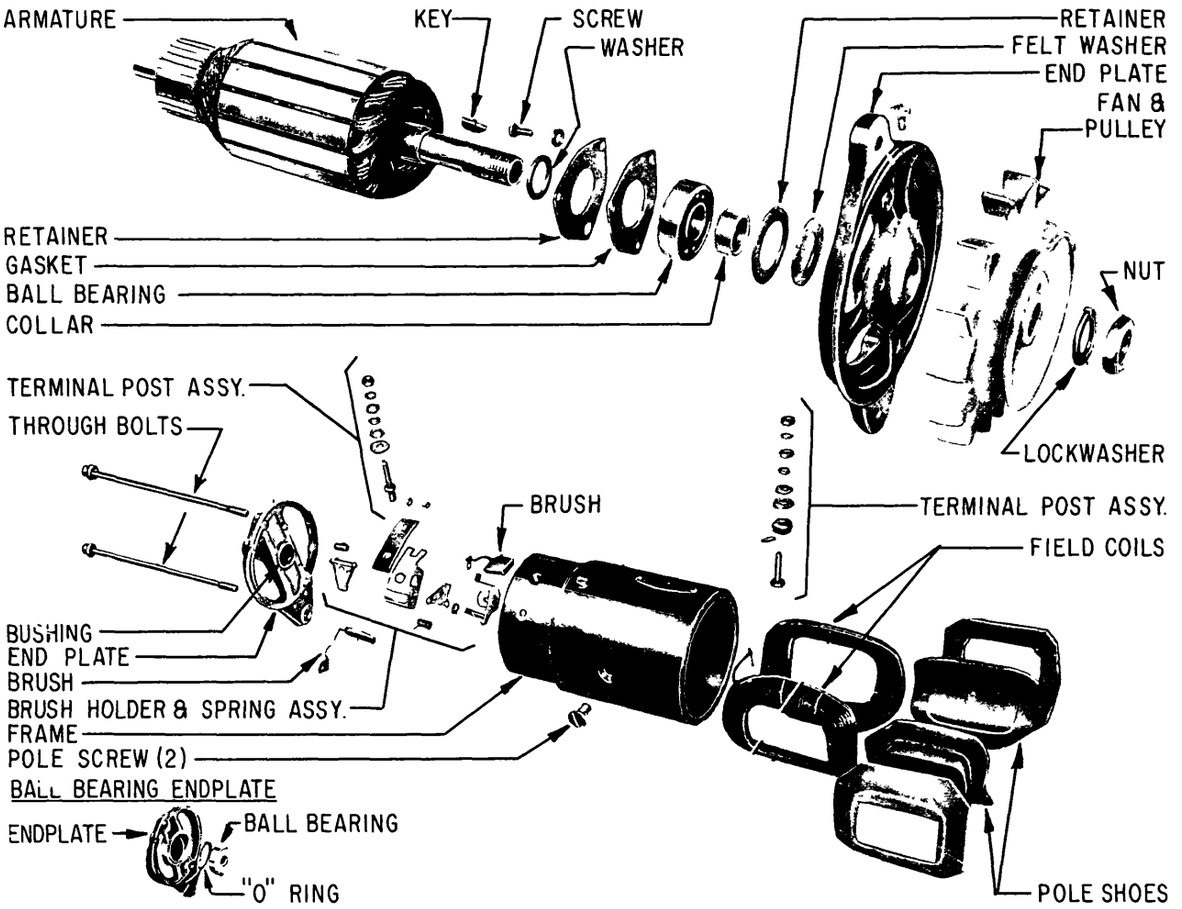
Ground Circuit Resistance ("A" Circuit): Leave rheostat and ammeter connected as in "Charging Circuit Resistance" test above, Connect voltmeter from negative (grounded) battery post to generator frame. Start engine and adjust accessory load and rheostat to give 20 ampere reading on ammeter Maximum voltage drop should not exceed .1 volt.

CONTINUED ON NEXT PAGE

"A" & "B" CIRCUIT INTERNAL WIRING

DELCO-REMY "EXTRUDED FRAME" GENERATORS (C nt.)

OVERHAUL: **Disass mbly** - Remove cover band (if equipped). Remove through bolts and remove commutator endplate. *NOTE - Hook brushes up and away from commutator to prevent damage and loss of parts.* Remove drive endplate and armature assembly from frame. Remove pulley nut, lockwasher, pulley and fan, and key from shaft. Press commutator ball bearing (if equipped) from armature shaft, then press drive endplate and bearing assembly from shaft. Slide spacer washer off armature shaft. Remove drive endplate bearing retainer, gasket, bearing, retainer, and felt washer from drive endplate.



Insp cti n - Clean and dry all parts. Do not use solvent on armature or field coils. Inspect all parts for wear, scoring, roughness, burning, evidence of overheating, worn insulation, poor solder connections, etc.

Armature; Inspect shaft for wear or scoring and replace armature assembly if necessary. Check armature windings for shorts on a growler. Check for short to shaft and for open circuit between segments with a test lamp. If commutator rough or out-of-round, reface as necessary, removing as little metal as possible. Undercut mica segments 1/32" deep and square the full width of slot. Polish commutator with No. 00 sandpaper. Wipe commutator thoroughly to remove dirt and copper dust.

Field Windings: Make tests with a 110-volt test lamp. Check for open circuit between field coil lead and "ARM" terminal. Check for ground between "FLD" terminal and frame. Check "ARM" terminal for ground with frame. Check field current draw as follows: Connect an ammeter from battery positive post to "ARM" terminal. Connect "FLD" terminal to battery negative post. Connect "ARM" and "FLD" terminals ("A" circuit), field coil brush lead and "FLD" terminal ("B" circuit) with voltmeter. Note field current draw. *See Car Model pages for sp cifications.* High current reading indicates a short or incorrect coils; low current reading indicates poor connections, high resistance, or incorrect coils. Check for short circuits, high resistance, or incorrect coils. Replace field coils as necessary.

Brush s: Check brushes for free fit in holders, accumulation of dirt and for wear. If worn to less than ½ original length (compare with new brushes), replace brushes. Check brush spring tension with spring scale at right angle to brush arm. Note reading just as brush arm is lifted from brush. If not within specifications, replace springs. *See Car Model pages for specifications.* Check insulated brush holder for ground with endplate or frame. If ground exists, replace endplate (if brushes mounted in endplate) or replace brush holders.

Bearings: If bronze bushing worn or scored, replace bushing or endplate as required. Clean ball bearings with solvent and blow dry with air. *Do not spin.* Check bearings for wear, scoring, or roughness. Replace if necessary. Pack bearings with cam and ball bearing lubricant. Check "O" ring seal in groove in commutator endplate for distortion and replace if new bearing being installed. Clean "O" ring groove.

TYPICAL DELCO-REMY GENERATOR ASSEMBLY (EXPLODED)

Reassembly: Reverse disassembly procedure, installing all parts in proper order (see illustrations). Make sure "O" ring is seated in groove of commutator endplate before installing endplate (ball bearing endplate type). Saturate oiler wick with a few drops of light oil. After generator reassembled, check that bearings do not bind and that armature shaft turns freely.

POLARIZING GENERATOR: *Before operating, generator must be polarized as follows:*

"A" Circuit - MOMENTARILY touch a jumper wire between "ARM" and "BAT" terminals of regulator. *CAUTION - On generators with Double Contact regulators, insulate brushes from commutator before polarizing generator.*

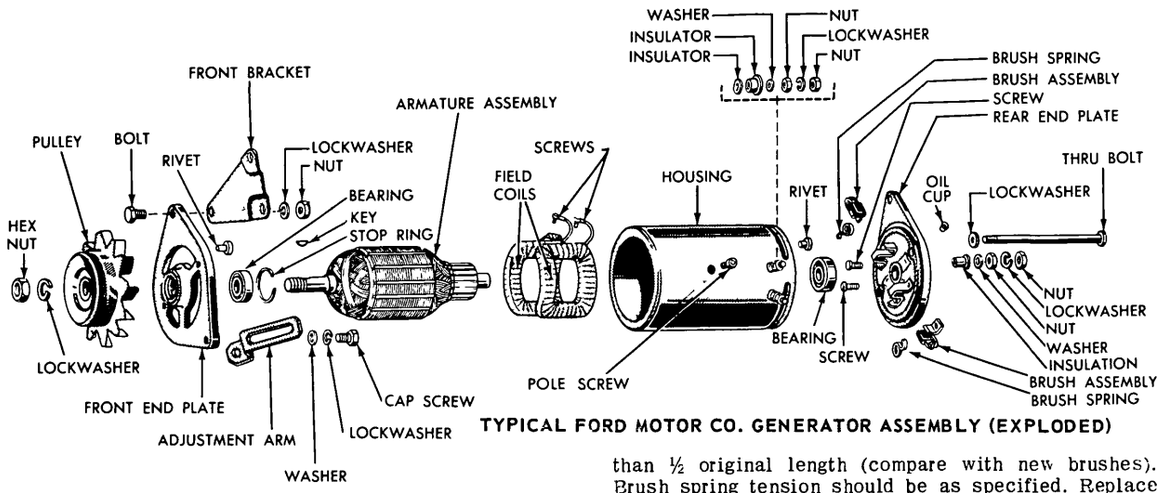
"B" Circuit - Disconnect field lead from regulator and MOMENTARILY touch this disconnected field lead to "BAT" terminal of regulator.

FORD MOTOR CO. GENERATORS

DESCRIPTION: Two pole, two brush, shunt generators of conventional design. Generators are force-draft air cooled by a fan built into drive pulley which rotates with armature shaft. Generators are of "B" circuit type with generator field grounded internally in the generator. *See illustration.*

LUBRICATION: Oiler for commutator endplate bronze bushing should be filled with a few drops of light oil every 5000 miles. Ball bearings are permanently lubricated.

►*GROUND POLARITY NOTE: Test connections given below are for negative grounded systems. If system is positive grounded, reverse test lead connections.*



►*CHARGING CIRCUIT FUSE CAUTION:* Some regulators may have a charging circuit fuse clipped to "BAT" terminal of starter relay (fuse may be bypassed on some cars). Check for blown fuse and cause of fuse failure when diagnosing generator, regulator, or battery failure. When making test connections for current output test, bypass fuse by disconnecting lead to fuse and attaching lead directly to circuit breaker at starter relay.

TESTING: Current Output - Connect an ammeter in series with regulator "BAT" terminal and lead to "BAT" terminal. Connect a voltmeter from regulator "ARM" terminal to ground. With engine idling, connect generator "FLD" and "ARM" terminals together with a jumper wire. Slowly increase generator speed to indicated RPM and note voltmeter and ammeter readings. *See Car Model pages for specifications.* Generator should reach or exceed maximum output.

Charging Circuit Resistance: Connect an ammeter between regulator "BAT" terminal and lead to "BAT" terminal. Connect voltmeter positive lead to "ARM" terminal of generator and voltmeter negative lead to battery positive post (or "BAT" terminal of starter relay). Connect generator "ARM" and "FLD" terminals with a jumper wire. Start engine, turn on light and accessories, and adjust engine RPM to give ammeter reading of 20 amperes. Maximum voltage drop should not exceed .8 volt.

Ground Circuit Resistance: Leave ammeter and jumper wire connected as in "Charging Circuit Resistance" test above. Connect voltmeter positive lead to starter motor rear endplate capscrew, and negative lead to generator frame. Start engine, turn on lights and accessories, and adjust engine RPM to give ammeter reading of 20 amperes. Maximum voltage drop should not exceed .1 volt.

OVERHAUL: Disassembly - Remove through bolts and remove commutator endplate. *NOTE - Hook brushes away from commutator to prevent damage and loss of parts.* Remove armature and drive endplate assembly from frame. Remove pulley, drive endplate, and key from armature shaft. Pull or press commutator end ball bearing from armature shaft. *NOTE - Remove bearing only if necessary as bearing will be distorted when removed from shaft and must be replaced.* On drive endplate, remove snap ring and press bearing from endplate.

TYPICAL FORD MOTOR CO. GENERATOR ASSEMBLY (EXPLODED)

Inspection - Wash all parts except armature, field coils, and bearings in solvent and wipe other parts with a clean cloth. Inspect parts for wear, roughness, scoring, worn insulation, evidence of burning, etc. Replace parts as necessary.

Armature: Check armature shaft for wear or scoring and replace armature if necessary. Check armature windings for short on a growler. With a test lamp, check armature for short circuit to shaft and for open circuit between segments. If commutator rough, scored, or out-of-round, reface as required, removing no more than 3/64" maximum from diameter of commutator. Undercut mica and polish commutator with No. 00 sandpaper.

Field Windings: Let field coil ground wire hang freely (disconnect from frame) and check field windings with a test lamp for open circuit from ground wire to "FLD" terminal. Test field for ground with frame with a test lamp. Test field current draw as follows: Connect an ammeter from "FLD" terminal to battery positive post. Connect battery negative (ground) post to generator frame. Field current draw should be as specified. *See Car Model pages for specifications. NOTE - If field current draw checked with generator in vehicle, disconnect "FLD" lead at generator or regulator and do not use a jumper from battery to generator frame.* Check "FLD" terminal for ground with frame. When replacing field coils, Pole Screw Remover and Installer, No. 10044, with generator clamped in a vise or arbor press, is recommended to prevent damage and to assure proper fit of parts.

Brushes: Brushes must be free in holders and free from excess dirt and oil. Replace brushes if worn to less than ½ original length (compare with new brushes). Brush spring tension should be as specified. Replace brush springs if not within limits. *See Car Model pages for specifications.* Check insulated brush holder for ground with endplate. If ground exists, replace endplate.

Bearings: If commutator endplate bronze bushing is worn or scored, replace bushing or endplate as required. Replace ball bearings if worn, scored, loose, or if lubricant lost. *NOTE - Commutator end ball bearing will be distorted if removed from shaft and must be replaced. Drive rear bearing on shaft with a fibre mallet with socket or spacer against inner race of bearing.*

Reassembly: Reverse disassembly procedures, assembling all parts in proper order (see illustration). Make sure drive end bearing snap ring is in position against bearing in drive endplate.

POLARIZING GENERATOR: *Before operating, generator must be polarized as follows:* Disconnect field lead form "FLD" terminal of regulator and MOMENTARILY touch this disconnected wire to "BAT" terminal of regulator. *Do not use a jumper wire or regulator points will be burned instantly.*

FORD MOTOR CO. GENERATOR INTERNAL WIRING

BOSCH GENERATORS

DESCRIPTION: The heavy duty type generator is a four pole, four brush, "B" circuit (field grounded in generator through grounded brush), shunt generator of conventional design Generator is force-draft air cooled by a fan built into drive pulley which rotates with armature shaft. Armature shaft is supported by a ball bearing at both drive and commutator ends

TESTING: Curr nt Output - Disconnect "ARM", "FLD", and "BAT" leads from regulator Tape "BAT" terminal lead Connect ammeter positive lead to "ARM" and "FLD" leads with a carbon pile rheostat in series with ammeter, and negative ammeter lead to engine ground strap. Connect voltmeter positive lead to regulator "ARM" and "FLD" leads and voltmeter negative lead to ground Turn all resistance into the circuit Start engine and set at 800 RPM. Slowly turn resistance out of circuit until voltmeter reads 14 volts Generator should reach or exceed maximum rated output *See Car Mod l pages f r specifications*

Charging Circuit Resistance: Connect an ammeter between regulator "BAT" terminal and lead to "BAT" terminal. Connect voltmeter positive lead to "ARM" terminal of generator and voltmeter negative lead to battery positive post Start engine, turn on lights and accessories, and adjust engine RPM to give ammeter reading of 20 amperes Maximum voltage drop should not exceed 5 volt

Gr und Circuit R sistanc : Connect an ammeter between regulator "BAT" terminal and lead to "BAT" terminal Connect voltmeter positive lead to battery negative (ground) post, and negative lead to generator frame Start engine, turn on lights and accessories, and adjust engine RPM to give ammeter reading of 20 amperes Maximum voltage drop should not exceed 2 volt

OVERHAUL: Disassembly - Remove commutator end band and sealing strip for access to brushes Remove brushes Remove nut, washers, pulley, and key from shaft Remove drive endplate attaching screws and remove drive endplate and armature assembly Remove drive end bearing retainer plate-to-drive endplate attaching screws and remove armature from drive endplate Remove commutator endplate attaching screws and remove endplate Remove spring washer from commutator endplate Remove bearings from endplates with a jaw type bearing puller

Inspection - Wash all parts except armature, field coils, and bearings in solvent Inspect all parts for wear, damage, worn insulation, etc

Armature: Inspect shaft for wear or scoring and replace armature assembly if necessary Check for shorted windings on a growler Check for short to shaft with a test lamp Check for open circuit between segments with a test lamp If necessary to turn commutator, DO NOT remove more than 3/64" maximum diameter of commutator Undercut mica segments and polish commutator with No 00 sandpaper

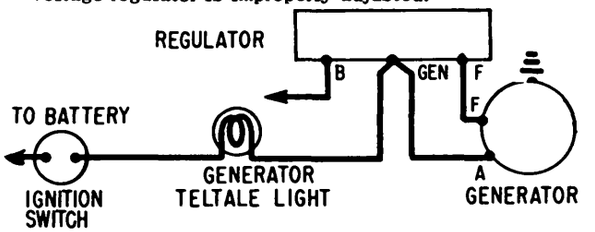
Field Windings: Remove ground wire from frame and let hang freely Check field coils for open or short circuit with a test lamp Check field current draw *See Car Model pages for specifications*

Brushes: Test insulated brush holders for ground with endplate If ground exists, replace endplate Brushes must be free in holders Replace brushes if worn more than ½ of original length of 1 125" Check brush spring tension and replace springs if necessary *See Car Model pages for specifications*

Bearings: Replace bearings if scored or worn *See Re-assembly" below for installation procedure*

R ass mbly: Position drive end bearing retainer plate on drive end of armature shaft and press drive end bearing on shaft Place spacer on commutator end of shaft and press commutator end bearing on shaft with sealed side of bearing toward armature winding Insert spring washer into bearing bore of commutator endplate with washer prongs facing bearing and install commutator endplate on frame Tighten attaching screws to 25-30 inch-lbs Place armature in drive endplate and tighten bearing retainer plate screws Assemble armature and drive endplate into frame and tighten endplate attaching screws to 30-35 inch-lbs *NOTE - Be sure bearings and armature turn freely* Install brushes Install commutator endplate sealing strip and band Install key, pulley, washers and attaching nut Tighten nut to 45-55 ft lbs

POLARIZING GENERATOR: *Before operating, generator must be polarized as follows* Disconnect regulator "FLD" wire from regulator "FLD" terminal and MOMENTARILY touch wire to "BAT" terminal of regulator *CAUTION - DO NOT use a jumper wire or regulator will be damaged*



GENERATOR TELTALE LIGHTS

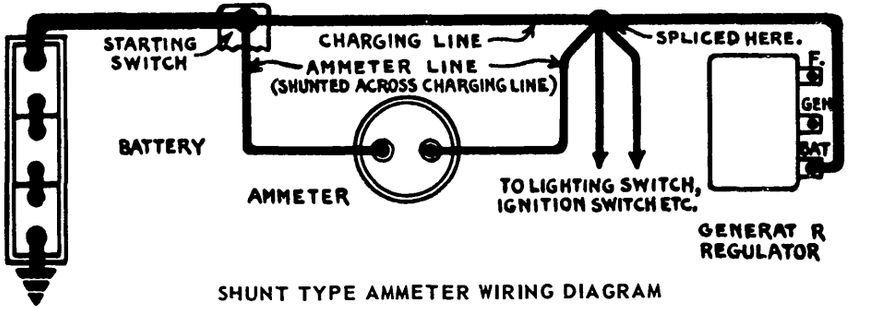
DESCRIPTION: Consists of an indicator light bulb mounted in instrument panel cluster and connected to the ignition switch and grounded through the generator. Light goes on when ignition switch turned on and should go out when generator begins to charge. *NOTE* – On some cars, indicator light circuit is protected by a fuse. *See individual Car Model pages and Car Model wiring diagrams.*

TROUBLE SHOOTING & DIAGNOSIS: Light Off, Ignition On, Engine Stopped – Indicator bulb burned out. Open circuit or loose connections in light circuit. Blown indicator light circuit fuse (if equipped).

Light On, Engine Running: Low idle speed. Low generator output. Faulty generator. Improperly adjusted regulator. Generator field improperly grounded.

TESTING: *CAUTION – On cars with Double Contact Voltage Regulator, DO NOT ground regulator "FLD" terminal when making test. Disconnect regulator fi ld leads and ground leads before testing.* Connect a jumper wire from regulator "FLD" terminal to ground with engine running at medium speed. If indicator light goes out, generator field circuit is improperly grounded, or voltage regulator is improperly adjusted.

TYPICAL TELTALE LIGHT WIRING



SHUNT TYPE AMMETER

►***CAUTION—When testing voltage regulators on the above cars with shunt type ammeters, and the "BAT" lead is removed from the regulator for the test, it is of utmost importance that the other leads on same terminal be bolted to the "BAT" lead when it is removed. Failure to do this may result in burning up th wiring harness.***

IMPORTANT NOTE: Accessories must not be connected at ammeter terminals as ammeter circuit wires are inadequate to carry more than designed load and any change in ammeter circuit will cause ammeter to read incorrectly.

DESCRIPTION: External shunt type ammeter with push-on type terminals This design lessens number of connections in generator charging circuit and results in better generator performance (less chance for loose or corroded connections and high resistance in circuit).

OPERATION: Ammeter operates in usual manner except only a portion of the charging current (approximately 10%) goes through the ammeter, remainder of charging current being 'shunted' around ammeter through regular charging line (see illustration). Ammeter dial is calibrated so that it indicates entire charging current (25-30 amperes) rather than current actually in ammeter circuit. Correct ammeter operation is dependent on proportional amount of current in each branch of the circuit (through ammeter and through the external shunt) and any disturbance of this balance (such as connection of accessories at ammeter terminals) will cause ammeter to read incorrectly

SHUNT TYPE AMMETER WIRING DIAGRAM

AUTOLITE 6-VOLT "A" CIRCUIT REGULATORS

►*GENERATOR REPOLARIZING:* Whenever regulator or generator leads are disconnected for ANY reason, the generator must be repolarized as follows After generator and regulator leads are reconnected, connect jumper wire between "GEN" and "BAT" terminals momentarily to allow a quick current surge through generator windings. This will prevent damage to equipment caused by reversed polarity (vibration, arcing, and burning of contact relay points).

►*NORMALIZING THE REGULATOR:* Before checking regulator, bring it up to normal operating temperature as follows Operate generator at speed of 1500 RPM, adjust charging rate to 10 amperes (connect .25 ohm resistor in charging line or use variable resistance connected across battery). Continue operation for 15 minutes to "normalize" the regulator or bring it up to operating temperature (temperature can be checked by placing an accurate thermometer 2" from cover)

DESCRIPTION: The Regulators that follow are all of the "Temperature Compensated" type consisting of a CUT-OUT UNIT, a VOLTAGE CONTROL UNIT and a CURRENT REGULATING UNIT When correctly adjusted, test readings will be the same as appear in the tables below

CHECKING & ADJUSTMENT (CUT-OUT RELAY): Check and adjust contact gap and air gap first before checking closing and opening voltage

Air Gap: 031- 034" (Exc VBO), 025- 027" (VBO) Use flat gauge (ST-281-9) to measure between magnet core and armature at a point as close to armature hinge as possible **with contacts open.** Adjust by bending armature stop and make certain that stop does not rub against edge of armature
NOTE—Armature 'seals' against yoke after contacts close (measure air gap with contacts open)

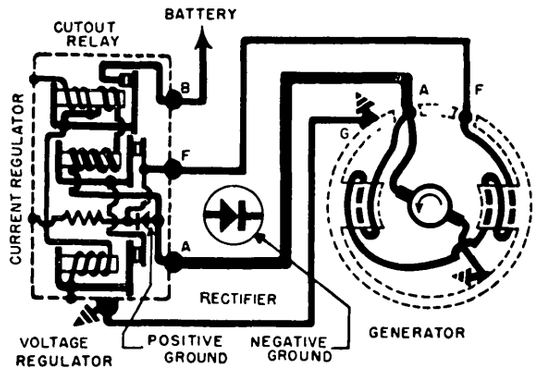
Contact Gap— 015" Min (all models) Gap must not be less than 015" but may exceed this figure in service With correct adjustment, contacts will close and armature will then 'seal' against yoke CAUTION—If contact gap too large, contacts will not close before armature seals against yoke

Closing Voltage—Connect ammeter in charging line at regulator 'B' terminal, connect voltmeter between 'A' terminal and ground Operate generator and increase speed slowly until contacts just close **but without sealing against yoke,** note voltmeter reading at this point To adjust, use Tool ST-283, adjust armature spring tension by bending lower spring hanger ***CAUTION***—Closing voltage must always be 5 volt less than voltage regulator setting

Opening Voltage or Amperage—Connect meters as for Closing Voltage Check (above), decrease generator speed slowly and note voltmeter (or ammeter) reading as contacts open Adjust by changing contact gap (see above)

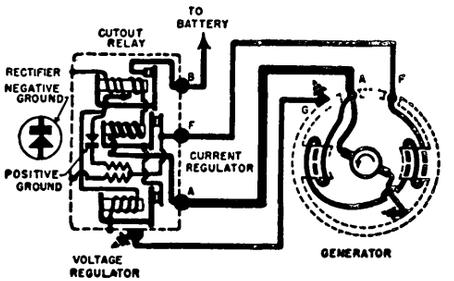
Cutout Relay Settings

Model	Contact Closing Voltage	Contact Opening Voltage
VAV	6 3-6 8	4 1-4 8
VBA	6 3-6 8	4 1-4 8
VBE	6 3-6 8	4 1-4 8
VBF	6 3-6 8	4 1-4 8
VBO	6 3-6 8	ℂ
VRP	6 3-6 8	4 1-4 8



ℂ - 4-6 amps discharge after a charge of 10 amps

CHECK & ADJUST (VOLTAGE REGULATOR):



Air Gap (All Series)— 048- 052" (pin gauge ST-281-7). Measure at stop pin on contact side with contacts just opening Test air gap by connecting test lamp and battery between 'F' terminal and ground Insert low limit pin gauge, depress armature by hand, lamp should dim or go out Repeat test with high limit pin gauge Lamp should remain lighted To adjust air gap, loosen screw holding upper contact bracket, raise bracket to increase gap, lower bracket and contact to decrease gap Contact spring must be straight and parallel with armature

►*1960 6 VOLT "VBO" REGULATOR VOLTAGE SETTING CHANGE (To Maintain Batt ry at Satisfact ry Charge Level):* **On later production regulators identified by Code Dates of 3R or later, or by a red dot on base of regulators with Code Date of 2R or earlier, the**

VBO-4200 REGULATORS

AUTOLITE 6-VOLT "A" CIRCUIT REGULATORS (Cont.)

voltage setting has been increased to 7.2-7.55 volts at 70°F. (ambient temperature) at a charge rate of 10 amperes or with a 1/4 ohm fixed resistor in series with the battery. Regulators with Code Date 2R or earlier which do not have the red dot may be recalibrated to new voltage setting if required.

Voltage Setting Check—Connect ammeter in charging line at regulator 'B' terminal (ammeter must read to 1 ampere and internal resistance must not exceed 01 ohm, use short heavy leads for connections), connect voltmeter between regulator 'B' terminal and ground (meter must read to .1 volt). car battery must be fully charged (substitute fully charged battery if car battery run down). Run engine at speed equivalent to 30 MPH for at least 15 minutes with generator charging battery to bring regulator up to operating temperature. Then note voltmeter reading (see voltage table below).

Adjustment—Use tool ST-283 to vary armature spring tension by bending arm at lower end of spring. Replace cover and recheck performance.

Testing "Temperature Compensated" Current Regulators: ***CAUTION—Tests are made in two steps "Test A" and "Test B" as listed below.*** Connect test meters as directed for Voltage Regulator Check (above).

Test A—Operate generator for 15 minutes charging at ½ maximum rate (VAV, VBF, VRP Regulators), at 10 amperes (VBA, VBE, VBO Regulators), then note ammeter reading with current regulator operating Should agree with "Test A" figure in table below

NOTE—If regulator not cold at start of test, Test A reading may be slightly less than specified due to higher temperature.

►*TEMPERATURE CAUTION*—When checking regulator temperature with a thermometer, hold thermometer two inches away from regulator (must not touch regulator).

Test B—Add load on battery to hold voltage to "Test B" Table below to insure current Regulator operation Run generator for 15 minutes with current regulator operating, then note ammeter reading. Should agree with "Test B" figure in Current Setting Table below

"B" Test Voltage.

Adjustment (All Current Regulators): Use tool ST-283 to vary armature spring tension by bending arm at lower end of spring. Replace cover and recheck

REGULATOR RESISTORS: Resistors should be checked for correct resistance by testing with ohm meter (ST-284)

AUTOLITE 12-VOLT "A" CIRCUIT REGULATORS

►CHANGES & CAUTIONS

►*GENERATOR REPOLARIZING:* Whenever regulator or generator leads are disconnected for ANY reason, the generator must be repolarized as follows: After generator and regulator leads are reconnected, connect jumper wire between "GEN" and "BAT" terminals momentarily to allow a quick current surge through generator windings. This will prevent damage to equipment caused by reversed polarity (vibration, arcing, and burning of contact relay points).

►*1956 "VRX" 6201A REGULATOR PRODUCTION CHANGE:* Two resistors were used in early production regulators and three resistors were used in later regulators *See Resistor Table and Wiring Diagram below for differences.*

DESCRIPTION· Auto-Lite "VAT" and "VRX" Regulators are 12-volt types of similar design to previous Auto-Lite 6-volt regulators except for use of a third "R3" resistor on some "VAT" regulators. *See wiring diagram.*

►*CHECKING & ADJUSTMENT CAUTION* Removal of cover (for regulator adjustments) requires breaking of seal Regulator can be checked to determine if it is operating satisfactorily without breaking the seal or removing the cover as directed below

CHECKING REGULATOR (With ut br aking s al): Connect ammeter in charging line at regulator "BAT" terminal (in series with battery), connect voltmeter between regulator "BAT" terminal and ground Then check as follows

Voltage Regulator—Operate generator at speed corresponding to 30 MPH Adjust charging rate to 10 amperes (.25 ohm resistor can be used connected in charging line) Continue operation for 15 minutes to "normalize" or bring the regulator up to operating temperature (temperature can be checked by placing accurate thermometer 2" from the regulator cover) Note voltmeter reading. If this does not agree with with Voltage Regulator Setting given below, regulator is defective or requires adjustment

Current Regulator—Operate generator at speed corresponding to 30 MPH. Add load in excess of rated capacity shown on regulator cover (turn on car lights and accessories, add additional load such as carbon pile or lamp bank at point between ammeter and battery, or use variable resistance across battery) to insure current regulator operating. Continue operation for 15 minutes to "normalize" or bring the regulator up to operating temperature (temperature can be checked by placing accurate thermometer 2" from the regulator cover). Note ammeter reading If this does not agree with "Test A" figure in Current Regulator Setting below, regulator is defective or requires adjustment

CHECKING & ADJUSTMENT (Requiring C v r R m val): Connect ammeter in charging line at regulator "BAT" terminal (in series with battery), connect voltmeter between regulator "BAT" terminal and ground (except for Cutout Relay cut-in voltage test when voltmeter should be connected between regulator "ARM" terminal and ground) Make tests as follows

VOLTAGE REGULATOR

►*NORMALIZING THE REGULATOR* Before checking voltage setting, bring regulator to operating temperature as follows Operate generator at speed of 1500 RPM , adjust charging rate to 10 amperes (connect 25 ohm resistor in charging line or use variable resistance connected across battery). Continue operation for 15 minutes to "normalize" the regulator or bring it up to operating temperature (temperature can be checked by placing accurate thermometer 2" from regulator cover)

Air Gap· .048-.052". Check with wire gauge placed between armature and core at contact side of stop pin. Contacts should be closed with 052" gauge and should just open when armature pressed down against 048" gauge Adjust by loosening stationary contact support screw and raising or lowering the contact support

CONTINUED ON NEXT PAGE

AUTOLITE 12-VOLT "A" CIRCUIT REGULATORS (Cont.)

Voltage Setting: After regulator normalized (see above), and with generator charging at 10 ampere rate (VAT), 7 ampere rate (VBO, VRX), note voltmeter reading and regulator temperature. If voltage setting not within range shown in Voltage Regulator Setting specifications below, adjust regulator.

140°	14.6	140°	13.7

① - Plus or minus .3 volt. ② - Plus or minus .2 volt.
③ - Plus or minus .4 volt.

Adjustment—Decrease generator speed to slow idle, remove regulator cover, adjust voltage regulator by bending armature spring lower hanger down (increase spring tension) to increase voltage setting, or up (decrease spring tension) to lower voltage setting. After each adjustment, check setting by first cycling regulator (decrease speed until cutout relay contacts open, then increase generator speed to 1500 RPM) and then rechecking voltmeter reading and temperature with 10 ampere charging rate.

CURRENT REGULATOR
"Non-Temperature Compensated" Regulators

Current Setting: Connect test meters as directed under "Checking & Adjustment" above. Connect a load in excess of rated capacity of regulator at a point between regulator and battery (turn on lights and accessories, add additional load such as a lamp bank or carbon pile, or use a variable resistance across battery). Note ammeter reading with current regulator operating. Generator must be within 5% of rated capacity of regulator under test. *NOTE - Make test with regulator cover in place. Voltage regulator can be prevented from operating by installing a jumper across voltage regulator points.*

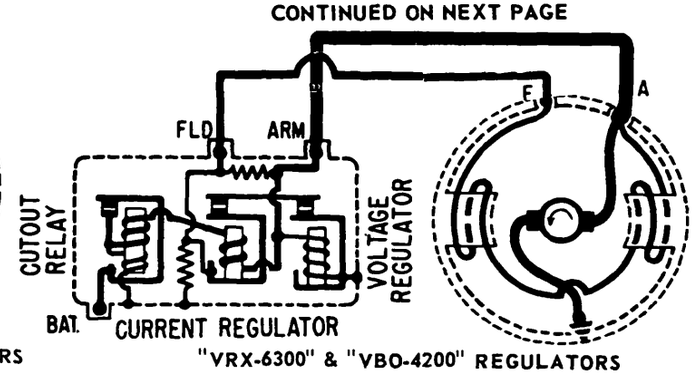
CURRENT REGULATOR
"Temperature Compensated" Regulators

►*NORMALIZING THE REGULATOR*· Before checking current setting, bring the regulator up to operating temperature by following steps (1) and (2) below.

(1)—Follow same procedure given above for Normalizing the Regulator for Voltage Setting checking. *If Current Regulator being checked immediately after checking and adjusting the Voltage Regulator, this step can be omitted. NOTE*—At end of this 15 minute operation, current setting should agree with "Test A" specifications in Current Regulator Setting given below.



(2)—Operate generator at speed of 2000 RPM., add load sufficient to cause current regulator to operate (turn on car lights and accessories, add additional load such as lamp bank or carbon pile, or use variable resistance across battery) with voltage of 13.7-13.9 volts (VAT Regulators), 13.6-13.8 volts (VRX & VBO Regulators). Continue operation for 15 minutes to "normalize" regulator by bringing it up to operating temperature (temperature can be checked by placing an accurate thermometer 2" from the regulator cover). *NOTE*—At end of this total 30 minute operation (steps 1 & 2), current setting should agree with

"VRX-6300" & "VBO-4200" REGULATORS

AUTOLITE 12-VOLT "A" CIRCUIT REGULATORS (C nt.)

"Test B" specifications in Current Regulator Setting given below.

Air Gap: .048-.052". Check and adjust in same manner as Voltage Regulator (above).

Current Setting: Normalize regulator (see above). Current regulator setting should then agree with "Test A" specifications in Current Regulator Setting table below. For "Test B", operate generator at 2000 RPM, and add sufficient load to cause current regulator to operate (turn on lights and accessories, add additional load such as a lamp bank or carbon pile, or use a variable resistance across battery) with voltage of 13.7-13.9 volts (VAT Regulators), 13.6-13.8 volts (VRX & VBO Regulators). Continue operation for 15 minutes to normalize current regulator by bringing it up to operating temperature (temperature can be checked by placing an accurate thermometer 2" from regulator cover). At end of the total 30 minute operation, current setting should agree with "Test B" specifications in Current Regulator Setting table below. If charging rate not within range shown in "Test B" column, adjust current regulator.

CUTOUT RELAY

►*NORMALIZING THE REGULATOR.* If regulator is cold, first bring it up to operating temperature as directed under Voltage Regulator above *If Cutout Relay checked immediately after checking Voltage & Current Regulator, no further normalizing will be required.*

Air Gap: .031-.034" (VAT & VRX), .025-.027" (VBO) with contacts open. Check with feeler gauge between lower face of armature and core as close to armature hinge as possible. The .031" and .025" gauges should be "GO", and .034" and .027" gauges "NO GO". Adjust by bending armature upper stop up or down as required.

Contact Gap: .015" minimum. Check with feeler gauge. Adjust by expanding or contracting the stationary contact support to lower or raise the contact.

Cut-in (Closing) Voltage: Connect ammeter in charging line at regulator "BAT" terminal (in series with battery), connect voltmeter between regulator "ARM" terminal and ground. Connect a variable resistance in the line between the regulator "FLD" and generator "F" terminal. With the regulator normalized (see above), operate the generator at the engine slow idle speed, set resistor so that full resistance is in the field circuit. Slowly turn resistance out of field circuit and note voltmeter reading at instant relay contacts close (needle will jump slightly). If cut-in voltage does not agree with settings shown below, adjustment is required. Adjust by bending armature spring lower hanger down (increase spring tension) to increase cut-in voltage, or up (decrease spring tension) to decrease cut-in voltage. Then check cut-out amperage.

Cut-Out (Opening) Amperage: After checking cut-in voltage (above), turn resistance completely out of field circuit and note ammeter reading. If ammeter does not indicate charging current of 10 amperes (VAT), 7 amperes (VBO & VRX), increase generator speed until correct ammeter reading is obtained. Turn resistance in field circuit slowly and note ammeter reading at point where ammeter indicates maximum discharge current (ammeter pointer will drop to zero, then go beyond the zero point, and finally return to zero). Take reading just before ammeter pointer snaps back to zero. This ammeter reading is the cut-out amperage and should agree with settings shown below. Adjust by varying the contact gap.

Cutout Relay Settings

Regulator	Volts Cuts-In	Amps. Cuts-Out
VAT 4002A, 2AX, 4AX	12.6-13.3	3.0-5.0
VAT All Others	12.6-13.6	3.0-5.0
VBO All Models	12.5-13.5	3.0-5.0
VRX 4001B, 1BX, 3AX, 3B, 3BX, 3C, 3CX	12.6-13.3	3.0-5.0
VRX 4004A, 5A, 5AX, 5003CX, 6201CX	12.6-13.3	3.0-5.0
VRX All Others	12.6-13.6	3.0-5.0

REGULATOR RESISTORS: Resistors should be checked for correct resistance with an ohm meter. For checking resistances of 3 resistor regulators without disconnecting resistors and coil, see below.

CHECKING RESISTANCES OF 3 RESISTOR REGULATORS (Without disconnecting resistors and coil): Block cut-out relay and voltage regulator contacts open, then proceed as follows.

1) Connect ohmmeter between "F" terminal and current regulator yoke. The reading should be 34.5-42 ohms (value of "R2" resistor). Any other reading indicates that "R2" is defective.

2) Connect ohmmeter between "A" terminal and ground. A reading of **24.8-28.3** (All VAT models and VRX 6010A, 6011A, 6201B models) **22.7-26.2** (VRX 6011B, 6201A models) indicates "R1", "R3", Cutout Relay and Current Regulator resistances are within specifications. If reading is 31-35 ohms, either "R1" or "R3" is open. If reading is **32.2-37 ohms** (All VAT models and VRX 6010A, 6011A, 6201B models), **28.8-33.4 ohms** (VRX 6011B, 6201A models), the Cutout Relay winding is open. If reading is **57.2-66.7** (All VAT models and VRX 6010A, 6011A, 6201B models), **47.2-56.0** (VRX 6011B, 6201A models), the Voltage Regulator winding is open.

CONTINUED ON NEXT PAGE

AUTOLITE 12-VOLT "A" CIRCUIT REGULATORS (Cont.)

3) If the above checks indicate that either "R1" or "R3" is open, proceed as follows Ground the "A" terminal and connect ohmmeter between "F" terminal and ground. A reading of 28-34.5 (all models), indicates that "R1" is open. A reading of 95-115 (all models) indicates that "R3" is open.

① - 3 Resistor Regulator. "R3" resistor marked "30", resistance is 28-34.5 ohms.

② - "R1" resistor on early production VRX 6201A regularors were marked "80", later production marked "60"

AUTOLITE 6 & 12-VOLT "B" CIRCUIT REGULATORS

► CAUTIONS

►*1960 6 VOLT "VBO" REGULATOR VOLTAGE SETTING CHANGE (To Maintain Battery at Satisfactory Charge Level)* On later production regulators identified by Code Dates of 3R or later, or by a red dot on base of regulators with Code Date of 2R or earlier, the voltage setting has been increased to 7 2-7 55 volts at 70°F (ambient temperature) at a charge rate of 10 amperes or with a 1/4 ohm fixed resistor in series with the battery Regulators with Code Date 2R or earlier which do not have the red dot may be recalibrated to new voltage setting if required

►*GENERATOR POLARIZING CAUTION* When regulator or generator leads are disconnected for any reason, then generator must be repolarized as follows With all wiring properly attached to both regulator and generator, disconnect generator field lead from its terminal on the regulator and momentarily touch it to the BAT terminal on regulator Re-attach field lead to field terminal on regulator This procedure will establish the correct polarity and prevent damage to the equipment

►*NORMALIZING THE REGULATOR.* Before checking regulator, bring it to normal operating temperature as follows Operate generator at a speed of 1500 RPM, adjust charging rate to 10 amperes (6 volt), 7 amperes (12 volt) by connecting a 25 ohm resistor in charging line or by using a variable resistance connected across battery Continue operation for 15 minutes to "normalize" the regulator or bring it up to operating temperature (temperature can be checked by placing an accurate thermometer 2" from cover)

DESCRIPTION: "Temperature Compensated" three unit type regulator assembly The charging system is a "B" circuit in which the generator field is grounded at generator ground brush and insulated in the voltage regulator from ground Field control resistors are inserted between field and armature circuits to control generator output *CAUTION - This type regulator must be used only with generators having internally grounded fields*

CHECKING & ADJUSTING: *See "Autolite 12-Volt 'A' Circuit Regulators" and note the following*

Voltage Setting: After regulator normalized (see above), and with generator charging at 10 amps (6 Volt), 7 amps (12 Volt), or with a 25 ohm resistor between regulator and battery, note voltmeter reading and regulator temperature If voltage not within range shown in Voltage Regulator Setting specifications below, adjust regulator *See "Autolite 12-Volt 'A' Circuit Regulators".*

BOSCH 12-VOLT REGULATORS

►*GENERATOR POLARIZING: (NOTE* - Polarization is not necessary except when generator has been rebuilt or if new pole shoes have been installed). To polarize a generator on the car, disconnect the field wire and the battery wire from the regulator and momentarily connect the two wires together (engine not running). *CAUTION - Do not polarize generator by any method that applies battery voltage to field terminal of regulator.*

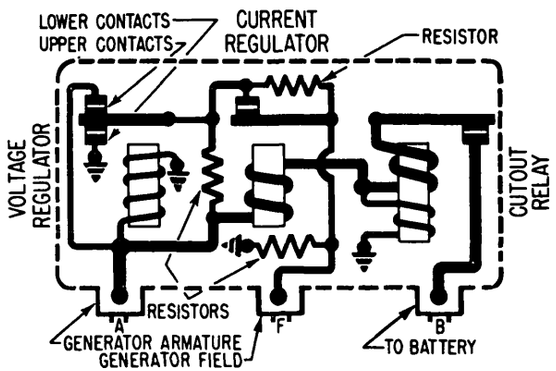
►*NORMALIZING THE REGULATOR:* **On the Car** - Clip special thermometer T56L-10505-A on regulator cover (see Note below). Operate engine with generator charging at 10 ampere rate for 30 minutes or until regulator temperature is stabilized.

On the Bench - Procedure is same as on the car except that a small fan should be mounted 12-15" from the regulator so as to circulate air over the regulator cover while it is being warmed up.

Thermometer T56L-10505-A Note - This thermometer is calibrated in 10°F. increments and has additional Voltage scales indicating the correct voltage regulator setting for each temperature reading (both 6 volt and 12 volt scales provided).

►*AMBIENT TEMPERATURE NOTE:* Ambient temperature is the temperature taken adjacent to the regulator, using Thermometer T56L-10505-A.

DESCRIPTION: Three unit regulator containing cutout relay, voltage regulator and current regulator similar in design to other types, except that voltage regulator is two-stage unit operating on a double set of contacts. Voltage regulator is also temperature compensated.



OPERATION: Cutout relay and current regulator operate the same as other conventional units. Voltage Regulator operates in two stages as follows:

Upper Contact Voltage Regulator Operation: With generator at low speeds, regulator armature vibrates on upper set of contacts and limits voltage by intermittently inserting resistance into generator field circuit. With contacts open there is no resistance in field circuit, and with contacts closed, resistance (R1) is inserted. This process continues until transfer point to lower stage operation occurs (transfer point almost instantaneous).

Lower Contact Voltage Regulator Operation: When generator at high speeds or when battery fully charged and electrical load is light, voltage rises and pulls armature down so that it vibrates on lower set of contacts. With lower contacts closed, field current is shunted to ground and with contacts open resistor (R1) is inserted in circuit.

CHECKING & ADJUSTING: *CAUTION* - Regulators are temperature compensated and must be brought up to normal operating temperature before checks are made. This normal temperature is that existing adjacent to the regulator cover after ½ hour of operation in the car or after the regulator has been heated until the temperature is stabilized (standard normal temperature is 75°F.).

►*TEST METER CONNECTIONS:* If special Test Sets used, make all connections in accordance with manufacturer's instructions. If individual meters used, make connections as follows: Connect test ammeter and 1½ ohm fixed resistor in series in charging line at regulator "BAT" terminal, from regulator terminal to ground (Ford). *CAUTION - Disconnect battery cable.* On other cars, connect test ammeter and 1½ ohm fixed resistor in series in charging line at regulator "BAT" terminal in series with battery. Connect voltmeter between regulator "ARM" terminal and ground (regulator base or battery grounded terminal). Connect a 50 ohm variable field rheostat (2 amp. rating) in generator field circuit (disconnect field lead at regulator "FIELD" terminal, connect rheostat between this lead and regulator "FIELD" terminal)

BOSCH 12-VOLT REGULATORS

CUTOUT RELAY

Cut-In (Closing) Voltage: After regulator normalized and with test meters connected (see above), check cut-in voltage as follows:

Ford - With field resistance completely turned in the field circuit, operate engine at 1500 RPM, slowly turn resistance out of field circuit and note voltmeter reading when relay contacts close (pointer will drop back slightly). Repeat this check several times by turning resistance in and out of field circuit.

Lincoln & Mercury - With resistance turned out of field circuit; slowly increase generator speed and note voltmeter reading at instant relay contacts close (pointer will drop back slightly). Repeat this check several times by decreasing generator speed until contacts open and then increasing speed until contacts close. If closing voltage not correct as shown in setting table below, adjustment is required.

Adjustment - Bend cutout relay spring adjusting arm upward to increase voltage, downward to decrease voltage.

Cut-In (Closing) Voltage Setting

All Models - 13.0-13.5 volts.

Cut-Out (Opening) Discharg Curr nt: This can be checked after checking cut-in voltage by increasing generator speed (or turning out field resistance) until charging current is approximately 10 amperes, then slowly decrease generator speed (or turn in field resistance) until maximum **dischargcurrent** indicated on ammeter (ammeter will return to zero as contacts open).

Cut-Out (Opening) Discharg Current

All Models - 2-8 amperes.

VOLTAGE REGULATOR

V ltage Setting: After cutout relay checked and adjusted, cycle regulator by decreasing speed until cutout relay

CONTINUED ON NEXT PAGE

BOSCH 12-VOLT REGULATORS (Continued)

contacts open. Clip special thermometer on regulator cover to establish regulator ambient temperature and corresponding voltage setting (see Voltage Regulator Settings for various ambient temperatures below). Run engine at 750 RPM and note voltmeter reading. This is **Upper Contact voltage regulator setting. Increase engine speed to 1500 RPM and note voltmeter reading. This is Lower Contact voltage regulator setting. If setting not within limits listed in Setting-Temperature table below, adjustment is required.**

Adjustment - Bend voltage regulator spring adjusting arm upward to decrease voltage, downward to increase voltage.

Final Test (Ford) - Remove all test leads except voltmeter leads and connect "BAT" and "F" wires to regulator. Run engine at 1500 RPM (under battery load) and note voltmeter reading (voltage will rise to regulated value after a few moments operation).

Voltage Regulator Settings (Ambient Temperature Correction)

Ambient Temp.(°F)	Lower Contacts (Volts)	Upper Contacts (Volts)
25°	14.4-14.9	14.4-15.1
35°	14.3-14.8	14.3-15.0
45°	14.3-14.8	14.3-15.0

145°	13.7-13.2	13.7-14.4

℄ - Standard Setting

CURRENT REGULATOR

Current Setting: This check requires that a load be added, or that the generator voltage be dropped to approximately 13 volts, to cause current regulator to operate. It is recommended that a heavy duty variable resistance (carbon pile) be connected across the 1½ ohm fixed resistor in the charging line (connect resistance from ammeter lead terminal of fixed resistor to ground - see Test Meter Connections above). After voltage regulator checked (above), and with all resistance turned out of the field circuit, operate generator at 1500 RPM (Ford), 1000 RPM (Lincoln & Mercury), decrease the resistance of the carbon pile resistance until voltage drops to approximately 13 volts and ammeter reading is at maximum. This ammeter reading is the current setting. If not correct (see table below), adjust as follows:

Adjustment - Bend current regulator spring adjusting arm upward to decrease current, downward to increase current.

Current Setting

30 Amp. Regulator - 28-32 amperes
50 Amp. Regulator - 48-52 amperes
60 Amp. Regulator - 58-62 amperes

DELCO-REMY "1118825" & "1118900" SERIES REGULATOR

►*Data following covers both 6-volt and 12-volt Regulators.*

►*"1118825" & "1118900" SERIES REGULATOR NOTE:* Regulators of these series *with letter "B" following Model Number* differ from the "1118825" & "1118900" Series in that the direction of current flow through the Current Regulator Contacts has been reversed (see Wiring Diagram below). The molded insulator formerly located between connector strap and Current Regulator Support has been relocated between the attaching screw washer and the connector (both molded insulators are now on the same side of the connector strap).

►*ADJUSTMENT CAUTION:* When checking current regulators having the "B" suffix, DO NOT USE THE "Quick Check Method" outlined below for previous regulators of these series. Using a screwdriver inserted in hole in regulator base to short out voltage regulator will short out BOTH the voltage and current regulators and allow generator to operate without control.

DESCRIPTION: Regulators in series starting with Model 1118825 differ from previous models in that they do not include an accelerator or series winding on the voltage regulator unit. This difference makes necessary a different method of checking and adjusting voltage setting. "Circuit A" type regulators are used with generators having field insulated and grounded in Regulator.

TROUBLE SHOOTING: The existing conditions determine the "Normal" or "Abnormal" operation of Generator or Regulator as follows:

"Normal" Operation

1)–Battery fully charged and Low charging rate.
2)–Low battery and High charging rate.

"Abnormal" Operation

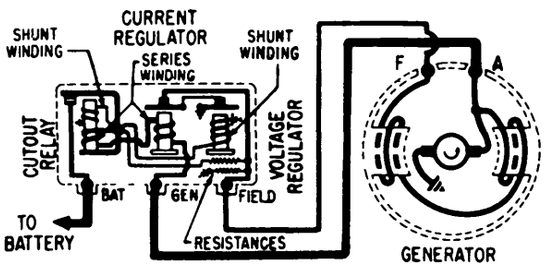
1)–Battery fully charged and High charging rate denotes defective or improperly adjusted Voltage Regulator unit, grounded field (Generator, Regulator, or Wiring), or high battery temperature permitting battery to accept high charging rate with "Normal" regulator setting.

2)–Low battery and low charging rate denotes loose connections or damaged wiring, defective battery, high circuit resistance, low regulator setting, oxidized Regulator points, defective Generator, Cutout Relay not closing, open series circuit in Regulator, or Generator, not properly polarized. Momentarily grounded "F" terminal. Generator O K if output increases with increased Generator speed.

3)–Burned Resistances, Windings, or Contact Points are caused by: Open circuit operation, open Resistance units or loose or intermittant connections in charging circuit. Check car wiring before installing new Regulator.

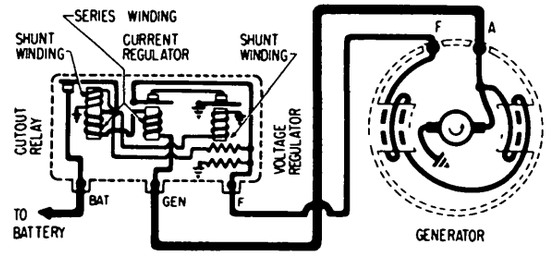
4)–Burned Relay Contact Points are due to reversed Generator polarity.

CHECKING & ADJUSTMENT



Regulator checks and adjustments should be made in the following sequence: Voltage Regulation, Cutout Relay Operation, and Current Regulation.

►*REGULATOR "NORMALIZING"* Before making any tests, it is important that regulator must be at **operating temperature.** Normalize regulator as follows: Connect ¼-Ohm resistor in series with battery (if variable resistor used, set to 1-10 ampere charging current), operate generator for 15 minutes at specified speed **with Voltage Regulator operating** (to normalize Voltage Regulator), or **with Current Regulator operating** (to normalize Temperature Compensated Current Regulators). This procedure not required for Non-temperature compensated Current Regulators.



"Specified Speed" Note–Generator RPM for checking and adjusting regulators should be: **Voltage Regulator**-3500 RPM (car & truck units), **Current Regulator**-sufficient speed to produce current in excess of specified current regulator setting.

►*GENERATOR REPOLARIZING CAUTION:* Repolarize generator each time regulator leads have been disconnected. Connect jumper lead momentarily between regu-

CONTINUED ON NEXT PAGE

DELCO-REMY "1118825" & "1118900" SERIES (NO SUFFIX LETTER) REGULATOR WIRING

DELCO-REMY "1118825" & "1118900" SERIES (WITH SUFFIX LETTER) REGULATOR WIRING

DELCO-REMY "1118825" & "1118900" SERIES REGULATOR (C nt.)

lator "Bat" and "Gen" terminals. Incorrect polarity will cause vibration and arcing and burning of Cutout Relay contacts.

►*POLARITY CAUTION:* Regulators are designed for a particular battery ground polarity as stamped on end of regulator base. Use of wrong polarity regulator will cause pitting of regulator contacts and shorten regulator life

VOLTAGE REGULATOR: Make checks and adjustments in the following order:

Air Gap - 075" (All models except 1118942,47,48,73), 063" (1118942,47,48,73). To check, press down on armature so that contacts just touch, measure air gap between armature and core. To adjust, raise or lower mounting bracket.

REGULATOR SETTING SPECIFICATIONS

1118912	5 9-6 7	6 9-7 4	50-54

Voltage Setting (6 & 12 v lt units)—Use either method as follows:

Fixed ¼-Ohm Resistance Method

1)—Connect ¼ Ohm—25 watt (Min) resistance in charging circuit at regulator "Bat" terminal **in series with with battery.**

►*CAUTION: Battery must remain in charging circuit. DO NOT disconnect battery as in checking procedure for previous series regulators.*

2)—Connect voltmeter from "Bat" terminal to ground

3)—Normalize regulator (see above) Limit electrical load to Ignition only.

4)—Cycle generator using either of the following methods: **(a)** Move voltmeter lead from "Bat" to "Gen" terminal of regulator, retard generator speed until generator voltage is reduced to 2 volts (6 volt units), 4 volts (12 volt units), then move voltmeter lead back to regulator "Bat" terminal, bring generator back to specified speed and note voltmeter reading. Or, **(b)** Connect variable resistance in field circuit (disconnect generator field lead at regulator "F" terminal, connect resistance between this lead and "F" terminal). With all resistance turned out, operate generator at specified speed, slowly increase resistance until generator voltage reduced to 2 volts (6 volt units), 4 volts (12 volt units), then turn out all resistance and note voltmeter reading. In each case, final voltage reading (after cycling generator) will be the voltage regulator setting.

5)—Adjust voltage regulator setting as follows Remove cover, turn adjusting screw on armature spring lower support clockwise to increase voltage setting, or counter-clockwise to decrease setting. After making adjustment, replace cover, cycle generator (step 4 above), and recheck voltage setting.

►*CAUTION*—Final setting should always be made by **increasing** spring tension (never by decreasing tension). If voltage setting too high, decrease spring tension below desired setting, and then increase spring tension for desired setting. If spring support does not return when screw backed off, back off screw for clearance between screw head and support, then bend support up carefully until it contacts screw head.

►*VOLTAGE SETTING CORRECTION FOR TEMPERATURE:* See "Regulator Settings" table (below) for voltage regulator setting range. Any setting within the range indicated is satisfactory provided battery and voltage sensitive equipment is operating properly and without damage. Before operating voltage is compared with specifications in the table, allowances must be made for variation in temperature (see table following). For regulator ambient temperatures below 125° F. SUBTRACT from operating voltage. For ambient temperatures above 125°F. ADD to operating voltage. The **adjusted operating voltage must be within the specified range indicated.**

ⒸAMBIENT TEMPERATURE is the temperature of the air surrounding the regulator approximately 1/4" from cover when regulator is at operating temperature ("Normalizing" procedure as given above should result in an ambient temperature of 125°F) and can be measured by placing a thermometer 1/4" from cover.

CONTINUED N NEXT PA E

DELCO-REMY "1118825" & "1118900" SERIES REGULATOR (Cont.)

Voltage Settings for Unusual Conditions: If battery is being Overcharged (Using too much water) or stays Undercharged (¾ charge or less), vary specified voltage regulator setting as follows:

Overcharged—Reduce Voltage Setting 0.1-0.2 volts and check after reasonable service period. Repeat until "Overcharge" corrected (water use normal). *NOTE*—Recheck cutout relay setting. Keep it 0.5 volts less than Voltage Regulator Setting.

Undercharged—Increase Voltage Setting 0.1 volt and recheck and repeat as above until condition corrected.

►*CAUTION: Avoid settings so high that damage may be caused to lights or other sensitive equipment during cold weather operation. Before changing standard voltage regulator setting, correct all battery conditions such as: Sulphated Plates, Overheating due to operating location, or Damage caused by overheating.*

Variable Resistance Method

1)—Connect variable resistance (25 watt Min.) and ammeter in series at "Bat" terminal of regulator and in series with battery.

►*CAUTION—Battery must remain in charging circuit. DO NOT disconnect battery as in checking procedure for previous series regulators.*

2)—Operate generator and adjust resistance to 10 ampere charging rate. Operate generator for 15 minutes with regulator cover in place to attain operating temperature.

3)—Cycle generator and adjust regulator voltage in same manner as in "Fixed Resistance Method" (steps 4 & 5) above.

CUTOUT RELAY: Air Gap and Contact Gap should be checked and adjusted with "Bat" lead disconnected from regulator.

Air Gap—.030" (All Models). To check, press down on armature until contacts just close (both sets of contacts must close at same instant), measure gap between armature and center of core. To adjust, loosen two armature hinge screws on back of frame, raise or lower armature as required.

Contact Gap—.020" (All Models). Adjust by bending upper armature stop.

Closing (Cuts-in) Voltage—Connect regulator to proper generator and battery, connect Voltmeter between regulator "Gen" terminal and ground. Check closing voltage by either of the following methods: (a) Slowly increase generator speed and note voltmeter reading at instant points close, then decrease generator speed and make certain that points open. Or, (b) With same connections as above, connect a variable resistance in the field circuit (disconnect generator field lead at regulator "F" terminal, connect resistance between this lead and "F" terminal—see note below for resistance values), operate generator at medium speed with all resistance cut in field circuit, slowly cut out resistance until cutout relay points close, note voltmeter reading, then slowly cut in resistance to make certain that points open. Adjust cut-in voltage by turning adjusting screw under armature spring clockwise to increase cut-in voltage, or counter-clockwise to decrease cut-in voltage.

CURRENT REGULATOR: Make checks and adjustments in the following order:

Air Gap—.075" (All Models). Check and adjust in same manner as Voltage Regulator (above).

Current Setting—Any of the following methods can be used. All methods require that the Voltage Regulator be prevented from operating as detailed in the checking procedure.

Quick Check Method

►*CAUTION: Do not use this method on 1118825 and 1118900 Series Regulators with letter "B" following Model Number. See "Adjustment Caution" above.*

1)—Connect ammeter in charging circuit at regulator "Bat" terminal. Turn on all lights and accessories to provide load and cause current regulator to operate.

2)—Normalize regulator (see above). This procedure required for Temperature Compensated Current Regulators only (Non-temperature compensated units operate same cold or hot).

3)—Insert screwdriver blade through hole in regulator base and hold firmly with blade touching base and shield at same time. This will short out Voltage Regulator.

4)—Cycle generator (see Step 4 of Voltage Regulator Adjustment above), note ammeter reading which will be Current Setting.

5)—Adjust current regulator setting in same manner as voltage regulator (see Step 5 under Voltage Regulator above).

Load Method

1)—Connect ammeter in charging circuit at regulator "Bat" terminal. Connect load across battery equal to current regulator setting (use carbon pile or bank of lights).

2)—Normalize regulator (see above). This procedure required for Temperature Compensated Current Regulators only (Non-temperature compensated units operate same cold or hot).

3)—Cycle generator (see step 4 of Voltage Regulator Adjustment above), note ammeter reading which will be Current Setting.

4)—Adjust current regulator setting in same manner as voltage regulator (see Step 5 under Voltage Regulator above)

Jumper Lead Method

►*CAUTION—DO NOT use this method on Temperature Compensated Current Regulators.*

1)—Connect ammeter in charging circuit at regulator "Bat" terminal.

2)—Remove regulator cover and connect jumper lead across Voltage Regulator contacts (use short lead clipped to regulator armature and to stationary contact support).

3)—Turn on all lights and accessories, OR connect load across battery equal to current regulator setting (use carbon pile or bank of lights).

4)—Operate generator at specified speed and note ammeter reading which will be Current Setting.

5)—Adjust current regulator setting in same manner as voltage regulator (see Step 5 under Voltage Regulator above).

►*RADIO BY-PASS CONDENSER CAUTION:* Installation of such condensers on FIELD terminal of either the Regulator or Generator will cause regulator contacts to burn and oxidize which will reduce generator output. All such condensers should be disconnected and regulator contacts should be inspected and cleaned.

DELCO-REMY 6 & 12-VOLT REGULATORS "1119000", "1119100", "1119200","1972000" (SINGLE CONTACT)

►*"1118825" & "1118900" SERIES REGULATOR NOTE:* Regulators of these series **with Letter "B" following Model Number** are similar to "1119000" Series and all data below applies to these models also

DESCRIPTION: These regulators differ from preceding "1118825" and "1118900" series **without Letter "B" following the model number** in that the direction of current flow through the Current Regulator contacts has been reversed (see Wiring Diagram and Contact Mounting illustrations). **Air gap adjustment on some regulators is made by turning a nylon nut located at top of regulator unit All voltage regulators and some some current regulators are "temperature compensated".**

►*ADJUSTMENT CAUTION* When checking Current Regulator on these 1119000 series regulators, DO NOT use the "Quick Check Method" outlined for previous 1118825 series regulators Using a screwdriver inserted in hole in regulator base to short out Voltage Regulator will short out BOTH the Voltage and Current Regulators and allow generator to operate without control.

CHECKING & ADJUSTMENT: Make all checks and adjustments in following sequence Voltage Regulation, Cutout Relay Operation, and Current Regulation AFTER regulator has been brought up to normal operating temperature as directed below. Generator must be repolarized each time leads are reconnected and before operating

►*GENERATOR REPOLARIZING* After generator and regulator leads reconnected, connect jumper lead between regulator "GEN" and "BAT" terminals momentarily to allow a quick current surge through generator winding This will prevent damage to equipment caused by reversed polarity (vibration, arcing, and burning of relay contact points)

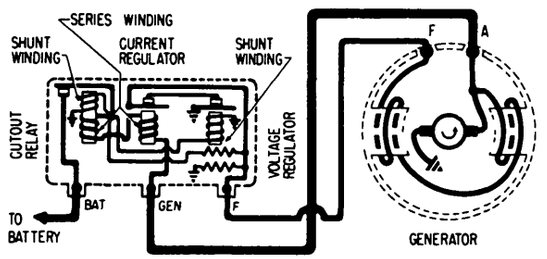
VOLTAGE REGULATOR

►*NORMALIZING THE REGULATOR* Before checking voltage setting, bring regulator to operating temperature as follows Connect 1/4 ohm resistance in series with battery, see that regulator cover in place, operate regulator for 15 minutes continuously with no other load than ignition *(NOTE*–If variable resistor used in place of fixed 1/4 ohm resistor, set resistor for 1-10 ampere charging rate).

Air Gap: .075" (except 1119004), .063" (1119004) with contacts just touching. Adjust by loosening upper contact mounting screws and raising or lowering contact bracket (models without nylon adjusting nut), by turning nylon adjusting nut (models with nylon nut). ***NOTE - On models without nylon adjusting nut, align contacts and tighten bracket mounting screws.***

V ltage Setting: With regulator **"Normalized"** (see above), setting can be checked using either **"Fixed Resistance"** or **"Variable Resistance"** method as indicated below.

Fix d 1/4 Ohm Resistance Meth d



1)–Connect 1/4 ohm fixed resistor (not less than 25 watts) in charging circuit at regulator "BAT" terminal (in series with battery), connect voltmeter between between regulator "BAT" terminal and ground.

2)–Cycle the generator using either of the following methods **(A)** Move voltmeter lead from regulator "BAT" terminal to "GEN" terminal. Reduce generator speed until voltmeter reading is 2 volts (6 volt types), 4 volts (12 volt types), then move voltmeter lead back to "BAT" terminal. **(B)** Connect variable resistance in field circuit (in line between generator and regulator "F" terminals), turn out all resistance, operate generator at 3500 RPM and turn in resistance until generator voltage reduced to 6 volts (6 volt types), 12 volts (12 volt types), then turn out all resistance and remove variable resistor.

3)–Operate generator at 3500 RPM (cars & trucks), note voltmeter reading with regulator cover in place. This is the voltage setting (see data below). Adjust by turning adjusting screw at voltage regulator armature spring lower bracket clockwise to increase setting, or counter-clockwise to decrease setting.

Variable Resistance Method

1)–Connect variable resistance (not less than 25 watts) and ammeter in charging circuit at regulator "BAT" terminal (in series with battery), connect voltmeter between regulator "BAT" terminal & ground

DELCO-REMY 12-VOLT REGULATORS WIRING DIAGRAM

2)–Cycle the generator (use either method outlined in step 2 of Fixed 1/4 Ohm Resistance Method above).

3)–Check and adjust voltage setting as outlined in step 3 of Fixed 1/4 Ohm Resistance Method above

Voltage Setting Specifications

Setting - As indicated in table below with regulator at a specific ambient temperature. When a voltage range only is given, set regulator within that range at 125°F ambient temperature. Regulator settings can be "tailored" to keep battery in satisfactory state under particular operating conditions as directed below.

►*AMBIENT TEMPERATURE NOTE* "Ambient Temperature" is the temperature of the air surrounding the regulator approximately 1/4" from the regulator cover when the regulator is at operating temperature ("Normalizing" procedure as given above should result in an ambient temperature of 125° F.) and can be measured by placing a thermometer 1/4" from the regulator cover **See tables below for specific regulator settings at various ambient temperatures if applicable.**

"Tailoring" Voltage R gulator Setting

If battery is consistently undercharged or overcharged (using too much water), adjust voltage regulator within range specified for the ambient temperature in which the regulator is operating, as directed above. ***CAUTION - Regulator setting above upper limit of range given for 125°F ambient temperature may caus damag to lights and other voltage sensitiv quipm nt and should be avoided.***

1)–Battery uses too much water. If voltage regulator setting **above** normal range listed above, reduce setting to within upper portion of normal range and check battery condition over a period of time. If voltage regulator setting **within** normal range listed above, reduce voltage setting 0.1 or 0.2 volts and check battery condition over period of time. This should be continued until battery remains charged.

2)–Batt ry is consistently und rcharged–If voltage regulator setting is **below** normal range listed above, increase setting to within lower portion of normal range and check battery condition over a period of

CONTINUED ON NEXT PAGE

DELCO-REMY 6 & 12-VOLT REGULATORS "1119000", "1119100", "1119200","1972000" (SINGLE CONTACT) (C ntinued)

time. If voltage regulator setting is **within** normal range listed above, increase voltage setting 0.1 volt and check battery condition over period of time. This should be continued until battery remains charged.

CUTOUT RELAY

►*ADJUSTMENT CAUTION: Disconnect battery lead before making Air Gap and Contact Gap adjustments.*

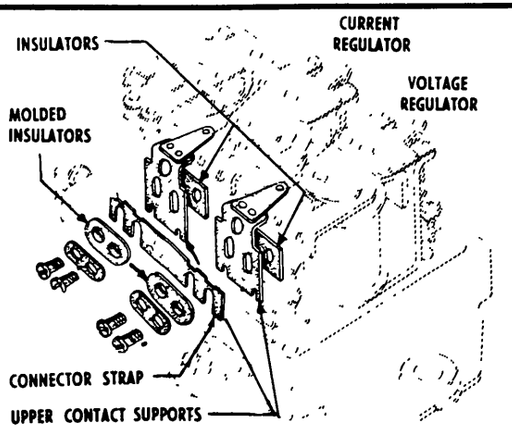
Air Gap: .020" with contacts just touching. To check, press down on armature until points just close (use finger pressure on armature directly above contacts), measure gap between armature and center of core. To adjust, loosen two screws at armature hinge on back of relay, raise or lower armature as necessary. *CAUTION*–Make certain that both sets of contact points close simultaneously.

Contact Gap: .020" with armature up against upper stop *(CAUTION*–Gap must be same for both sets of contacts to insure simultaneous closing). Use feeler gauge to check gap. To adjust, bend upper armature stop up or down as necessary.

Cut-in (Cl sing) V ltag : 6-Volt 5.9-6.7 volts (except 1119281), 5.9-6.5 volts (1119281); 12-Volt 11.8-13.5 volts (except 1119004), 11.5-13.0 volts (1119004). To check with regulator properly connected to generator and battery, connect voltmeter between regulator "GEN" terminal and ground. Use either of the following methods to check cut-in voltage:

1)–Slowly increase generator speed and note voltmeter reading at instant contacts close, then decrease generator speed and make certain that relay contacts open. See item (3) for adjustment.

2)–Connect a variable resistor in the field circuit between regulator "F" terminal and generator "F" terminal (use 15 ohm-25 watt resistor for 6 volt systems, 25 ohm-25 watt resistor for 12 volt systems). Operate generator at medium speed with all resistance turned in, slowly turn out resistance and note voltmeter reading at instant relay contacts close. Slowly turn in resistance and make certain that relay contacts open. Adjust as follows:



3)–Turn adjusting screw under armature spring (adjacent to contacts) in or clockwise to increase cut-in voltage, out or counter-clockwise to decrease cut-in voltage.

CURRENT REGULATOR

►*CHECKING & ADJUSTMENT CAUTION:* Temperature Compensated Current Regulators should be checked by the "Load Method" which provides for bringing the regulator up to operating temperature. Regulators which are not temperature compensated can be checked by the "Jumper Lead" Method.

Air Gap: .075" with contacts just touching. Check and adjust air gap in same manner as Voltage Regulator.

Curr nt S tting: Use correct method for each type as listed below. *CAUTION–Do not attempt to short out voltage regulator by inserting screwdriver through hole in base (will short out both voltage and curr nt r gulators and cause generator to operate without control).*

DELCO-REMY 12-VOLT REGULATORS CONTACT ASSEMBLY

Load Method

(For Temperature Compensated Regulators)

1)–Connect ammeter in charging circuit at regulator "BAT" terminal (in series with battery).

2)–Turn on all accessory load (lights, radio, etc.) and connect additional load (carbon pile rheostat or bank of lights) to reduce voltage to approximately 1.0 volt below voltage regulator setting.

3)–Operate generator at 3500 RPM (cars & trucks) for 15 minutes with regulator cover in place. This will bring regulator up to operating temperature.

4)–Cycle the generator by using either of the following methods: **(A)** Connect voltmeter between regulator "GEN" terminal and ground, reduce generator speed until voltmeter reading is 2 volts (6 volt systems), 4 volts (12 volt systems), then increase generator speed to 3500 RPM. **(B)** Connect variable resistance in field circuit (in line between regulator and generator "F" terminals), operate generator at 3500 RPM with all resistance turned out, turn in resistance until generator voltage reduced to 6 volts (6 volt systems), 12 volts (12 volt systems), then turn out all resistance.

5)–Operate generator at 3500 RPM and note ammeter reading which is the current setting. Adjust by turning the adjusting screw at the current regulator armature spring lower bracket clockwise to increase setting, or counter-clockwise to decrease setting.

Jumper Lead Method

(For Non-Temperature Compensated Regulators)

1)–Connect ammeter in charging circuit at regulator "BAT" terminal (in series with battery).

2)–Connect short jumper lead across voltage regulator points (from upper contact bracket to armature).

3)–Turn on all lights and accessories or connect additional load (see step 3 under Load Method above) to cause current regulator to operate.

4)–Operate generator at 3500 RPM (cars & trucks) and note ammeter reading which is the current setting. Adjust as directed in step (5) under Load Method above.

►CAUTIONS

►*REGULATOR CAUTION* *When testing generator and this type regulator, observe the following precautions*

1) *DO NOT GROUND GENERATOR FIELD WITH REGULATOR CONNECTED TO GENERATOR* - This will cause Lower Set of contacts in Voltage Regulator to burn up immediately.

2) *DO NOT FILE REGULATOR CONTACTS* - All contacts of the Double Contact Voltage Regulator are soft alloy and should be cleaned with crocus cloth or other fine abrasive and washed with carbon tetra-chloride.

DESCRIPTION: These regulators differ from other "1119000 Series" regulators in that a special "Double Contact" Voltage Regulator unit is used. Cutout Relay and Current Regulator units are same as units used in other 1119000 series regulators.

OPERATION: The Double Contact Voltage Regulator has an additional set of "Lower Contacts" connected directly across the generator field (in addition to the regular "Upper Contacts") and the regulating resistor is of lower value than on other type regulators. Regulator operates either on Upper Contacts or Lower Contacts, depending on load and battery requirements, as follows

Upper Contact Operation (Low Speed & High Load - High Generator Field requirement) - Regulator armature travel opens and closes upper contacts (vibrating action) cutting the regulating resistance in and out of the field circuit. This operation is the same as on other voltage regulators with single set of contacts.

Lower Contact Operation (High Speed & Low Load - Low Generator Field requirement) - Under these conditions, upper contact operation is not sufficient to control generator voltage. Regulator armature travel opens and closes lower contacts (vibrating action), shorting the field out (contacts closed) or cutting the regulating resistance in the field circuit (contacts open). This provides additional regulation.

CHECKING & ADJUSTMENT Make all checks and adjustments in following sequence Voltage Regulation, Cutout Relay Operation, and Current Regulation AFTER regulator has been brought up to normal operating temperature as directed below Generator must be repolarized each time leads are reconnected and before operating

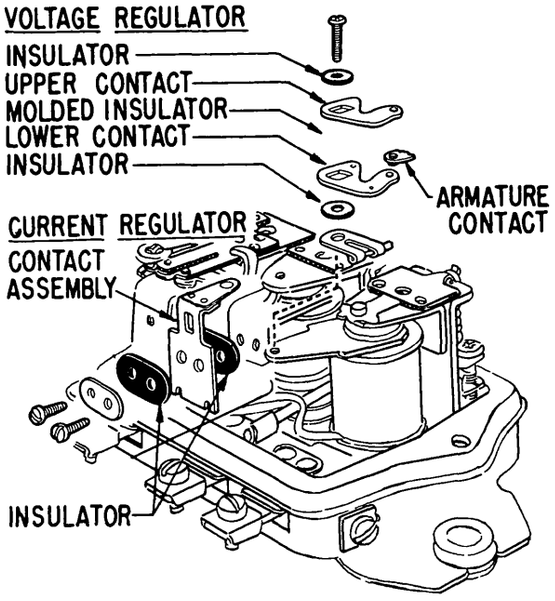
►*GENERATOR REPOLARIZING* After generator and regulator leads reconnected, connect jumper lead between regulator "GEN" and "BAT" terminals momentarily to allow a quick current surge through generator winding This will prevent damage to equipment caused by reversed polarity (vibration, arcing, and burning of relay contact points)

VOLTAGE REGULATOR

►*NORMALIZING THE REGULATOR* Before checking voltage setting bring regulator to operating temperature as follows Connect 1/4 ohm resistance in series with battery, see that regulator cover in place, operate regulator for 15 minutes continuously with no other load than ignition *(NOTE*–If variable resistor used in place of fixed 1/4 ohm resistor, set resistor for 1-10 ampere charging rate)

Air Gap: .080" with upper contact just touching. When adjusting air gap, turn air gap adjusting screw all the way out in a clockwise direction *(NOTE - This is the adjusting screw for voltage setting when operating on upper contacts),* then bend upper contact support for correct air gap

Contact Gap (Upper Set of Contacts): 016" with armature pressed down to point where lower contacts just touch Adjust by bending lower contact support



Voltage Setting: With regulator at specific ambient temperature, setting should be as indicated in "Setting Table" below when operating on **lower contacts.** When operating on **upper** contacts, setting should be 3- 5 volts below operating voltage on lower contacts Check and adjust as follows Battery should be fully charged so that charging rate is limited to 1-10 amperes (if charging rate is above 10 amperes, connect ¼ Ohm resistor in series with battery) Connect voltmeter from regulator "BAT" terminal to ground Connect a 25 Ohm (25 Watt) variable resistance in generator field circuit (between regulator "F" terminal and field lead normally connected to this terminal) *CAUTION - Resistor should have an "open" position at the full resistance end to assist in cycling the generator*

Operation on Lower Contacts Turn the field resistance completely out and operate generator at medium speed Regulator should then operate on lower set of contacts Continue operation for 15 minutes to bring regulator up to operating temperature then cycle generator by turning variable resistance to "open" position momentarily then slowly cut all resistance out Note voltmeter reading This is the regulator setting on LOWER CONTACTS and should be as indicated in table below for specific ambient temperature Adjust in usual manner by turning double-slotted screw on armature spring lower bracket

Voltage Regulator Setting

Ambient Temp. (F°)	Setting (Volts)
85°	14 1-14 9
105°	14 0-14 8
125°	13 8-14 6
145°	13 7-14 5
165°	13 5-14 4
185°	13 4-14 2
205°	13 3-14 1

Operation on Upper Contacts - After checking operation on Lower Contacts (above), slowly increase field resistance until regulator begins to operate on upper set of contacts (voltmeter should indicate a slight voltage drop at this point). Voltmeter reading should be .3 to .5 volts below lower contact operation setting for all models. Adjust by turning air gap adjusting screw located on top of armature (turn screw clockwise to increase voltage differential, counter-clockwise to decrease voltage differential). *NOTE* - This adjustment

DELCO-REMY REGULATOR CONTACT ASSEMBLY (DOUBLE CONTACT VOLTAGE REGULATOR)

will affect Voltage Setting on lower contact operation and entire checking procedure should be repeated.

►*ADJUSTMENT CAUTION*· If voltage setting on Upper Contacts is ever found to be HIGHER than voltage setting on Lower Contacts, it must be reduced by turning the air gap adjusting screw in a clockwise direction, and if the adjustment is taken up, **th nominal air gap must be reset (see below).**

CUTOUT RELAY

►*ADJUSTMENT CAUTION* *Disconnect battery l ad before making Air Gap and Contact Gap adjustments.*

Air Gap 020" with contacts just touching To check, press down on armature until points just close (use finger pressure on armature directly above contacts), measure gap between armature and center of core To adjust, loosen two screws at armature hinge on back of relay, raise or lower armature as necessary *CAUTION*–Make certain that both sets of contact points close simultaneously

Contact Gap 020" with armature up against upper stop *(CAUTION*–Gap must be same for both sets of contacts to insure simultaneous closing) Use feeler gauge to check gap To adjust, bend upper armature stop up or down as necessary

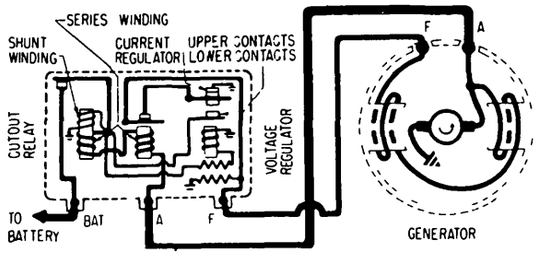
Cuts-in (Closing) Voltage: 11 8-13 5 volts To check with regulator properly connected to generator and battery, connect voltmeter between regulator "GEN" terminal and ground Use either of the following methods to check cut-in voltage

1)–Slowly increase generator speed and note voltmeter reading at instant contacts close, then decrease generator speed and make certain that relay contacts open See item (3) for adjustment

CONTINUED ON NEXT PAGE

1957 DELCO-REMY "1119100 SERIES" "DOUBLE CONTACT" REGULATORS (C ntinued)

2)–Connect a variable resistor in the field circuit between regulator "F" terminal and generator "F" terminal (use 15 ohm-25 watt resistor for 6 volt systems, 25 ohm-25 watt resistor for 12 volt systems). Operate generator at medium speed with all resistance turned in, slowly turn out resistance and note voltmeter reading at instant relay contacts close.



3)–Turn adjusting screw under armature spring (adjacent to contacts) in or clockwise to increase cut-in voltage, out or counter-clockwise to decrease cut-in voltage.

CURRENT REGULATOR

►*CHECKING & ADJUSTMENT CAUTION* Temperature Compensated Current Regulators should be checked by the "Load Method" which provides for bringing the regulator up to operating temperature. Regulators which are not temperature compensated can be checked by the "Jumper Lead" Method

Air Gap 075" with contacts just touching Check and adjust air gap in same manner as Voltage Regulator

Current S tting Use correct method for each type as listed below *CAUTION–Do not attempt to short out voltage regulator by inserting screwdriver through hole in base (will short out both voltage and current regulators and cause generator to operate without control).*

DELCO-REMY 1119100 SERIES (DOUBLE CONTACT VOLTAGE REGULATOR)

Load Method
(For Temperature Compensated Regulators)

1)–Connect ammeter in charging circuit at regulator "BAT" terminal (in series with battery)

2)–Turn on all accessory load (lights, radio, etc) and connect additional load (carbon pile rheostat or bank of lights) to reduce voltage to approximately 1.0 volt below voltage regulator setting.

3)–Operate generator at 3500 RPM (cars & trucks) for 15 minutes with regulator cover in place This will bring regulator up to operating temperature

4)–Cycle the generator by using either of the following methods **(A)** Connect voltmeter between regulator "GEN" terminal and ground, reduce generator speed until voltmeter reading is 2 volts (6 volt systems), 4 volts (12 volt systems), then increase generator speed to 3500 RPM **(B)** Connect variable resistance in field circuit (in line between regulator and generator "F" terminals), operate generator at 3500 RPM with all resistance turned out, turn in resistance until generator voltage reduced to 12 volts, then turn out all resistance.

5)–Operate generator at 3500 RPM and note ammeter reading which is the current setting Adjust by turning the adjusting screw at the current regulator armature spring lower bracket clockwise to increase setting, or counter-clockwise to decrease setting.

Jumper Lead Method
(For Non-Temperature Compensated Regulators)

1)–Connect ammeter in charging circuit at regulator "BAT" terminal (in series with battery)

2)–Connect short jumper lead across voltage regulator points (from upper contact bracket to armature)

3)–Turn on all lights and accessories or connect additional load (see step 3 under Load Method above) to cause current regulator to operate

4)–Operate generator at 3500 RPM (cars & trucks) and note ammeter reading which is the current setting. Adjust as directed in step (5) under Load Method above.

Current Setting Range

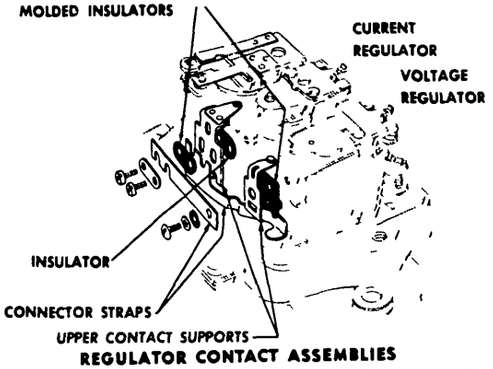
Regulator	Amperes	Regulator	Amperes
1119149	43-47	1119167	48-52
1119157	48-52	1119175	53-57
1119158	33-37	1119183	33-37
1119163	37-42	1119186	43-47

1958-60 DELCO-REMY "1119600 SERIES" 12-VOLT "DOUBLE CONTACT" REGULATORS

►*DOUBLE CONTACT REGULATOR CAUTION: These regulators do not operate in same manner as previous double contact regulators (1119100 Series).*

►*REGULATOR TESTING & SERVICE CAUTION: When t sting generator and this type regulator, observe the following pr cautions:*

1 - DO NOT GROUND GENERATOR FIELD WITH REGULATOR CONNECTED TO GENERATOR - This will cause upp r s t of contacts in Voltage Regulator to burn up immediately.



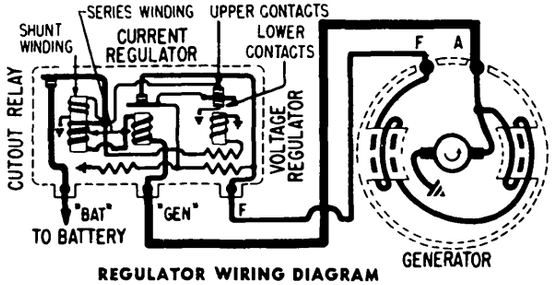
2 - DO NOT FILE REGULATOR CONTACTS - All contacts of the Double Contact Voltage Regulator are soft alloy and should be cleaned with crocus cloth or other fine abrasive and washed with carbon tetrachloride.

DESCRIPTION: These regulators differ from previous "Double Contact" Voltage Regulator units in that operation of the "upper" and "lower" contacts on the voltage regulator have been reversed and additional resistance is included for better regulation.

OPERATION: The Voltage Regulator has an additional set of "Upper Contacts" connected directly across the generator field (which shorts out generator field circuit). The "Lower Contacts" are connected in series with the generator field. The Voltage Regulator operates either on "Upper Contacts" or "Lower Contacts" (both sets are never in operation at the same time), depending on load and battery requirements, as follows

L wer C ntact Op ration (L w Sp d & High L ad–High G n rator Fi ld R quir ment) - Regulator armature travel opens and closes lower contacts (vibrating action) cutting regulator resistance in and out of field circuit. This operation is same as on regulators with a single set of contacts.

Upper Contact Operation (High Speed & Low Load - Low Generator Field Requirement) - Under these conditions, upper contact operation is not sufficient to control generator voltage. Regulator armature travel opens and closes upper contacts (vibrating action), shorting the field out (contacts closed) or cutting the regulator resistance in the field circuit (contacts open). This action provides additional regulation.



REGULATOR CONTACT ASSEMBLIES

CHECKING & ADJUSTING: Make all checks and adjustments in the sequence indicated below after regulator has been brought up to normal operating temperature. Repolarize generator each time leads are reconnected and before operating.

►*GENERATOR REPOLARIZING* After generator and regulator leads reconnected, connect jumper lead between regulator "GEN" and "BAT" terminals momentarily to allow a quick current surge through generator winding This will prevent damage to equipment caused by reversed polarity (vibration, arcing, and burning of relay contact points)

►*CHECKING & ADJUSTING CAUTION: "Temperatur Compensated" Current Regulators used on some units*

REGULATOR WIRING DIAGRAM

DELCO-REMY 1119600 SERIES DOUBLE CONTACT REGULATORS

1958-60 DELCO-REMY "1119600 SERIES" "DOUBLE CONTACT" REGULATORS (Continued)

(see table below). It is necessary that these regulators be adjusted to the setting specified for the "ambient temperature" of the unit. See "Ambient Temperature - Current Setting" table below.

CUTOUT RELAY

►*ADJUSTMENT CAUTION Disconnect battery lead before making Air Gap and Contact Gap adjustments.*

Air Gap 020" with contacts just touching To check, press down on armature until points just close (use finger pressure on armature directly above contacts), measure gap between armature and center of core To adjust, loosen two screws at armature hinge on back of relay, raise or lower armature as necessary *CAUTION*–Make certain that both sets of contact points close simultaneously

Contact Gap 020" with armature up against upper stop *(CAUTION*–Gap must be same for both sets of contacts to insure simultaneous closing) Use feeler gauge to check gap To adjust, bend upper armature stop up or down as necessary

Cut-In (Closing) Voltage: 11 8-13 0 volts (except 1119634), 11 5-12 7 volts (1119634) To check with regulator properly connected to generator and battery, connect voltmeter between regulator "GEN" terminal and ground Proceed as follows Connect a variable resistor in the field circuit between regulator "F" terminal and generator "F" terminal (use 25 Ohm, 25 Watt resistor) Operate generator at medium speed with all resistance turned completely in Turn on all lights or an equivalent load, then slowly decrease (turn out) resistance until cutout relay points close and note voltmeter reading which should be as indicated above To adjust, turn adjusting screw under armature spring (adjacent to contacts) in or clockwise to increase cut-in voltage, out or counterclockwise to decrease cut-in voltage

VOLTAGE REGULATOR

Air Gap: 067" with lower contacts touching To adjust loosen contact support bracket screw 1/8 turn and place a screwdriver in slot in contact support bracket and into molded insulator directly below contact support screw Raise handle of screwdriver to increase air gap and lower handle to decrease air gap *NOTE - Som regulators have an external adjustment screw for air gap adjustment*

Contact Gap (Upper Set of Contacts): 016" with lower contacts just touching (press armature down) Adjust by bending upper contact arm

Voltage Setting: With regulator at operating temperature setting should be as indicated in Voltage Setting - Ambient Temp table below, when operating on **upper contacts.** When operating on **lower** contacts, setting should be 1 to 3 volts below operating voltage on lower contacts Check and adjust as follows Battery should be fully charged so that charging rate is limited to 1-10 amperes (if charging rate is above 10 amperes connect ¼ Ohm resistor in series with battery) Connect voltmeter from regulator "BAT" terminal to ground Connect a 25 Ohm (25 Watt) variable resistance in generator field circuit (between regulator "F" terminal and field lead normally connected to this terminal) *CAUTION - Resistor should have an "open" position at the full resistance end to assist in cycling the generator*

Operation on Upper Contacts - With variable resistance turned out (minimum resistance), operate generator at medium speed, or a higher speed, so voltage regulator is operating on upper set of contacts *Continue to operate 15 minutes to establish operating temperature* (with regulator cover in place). Cycle generator by turning variable resistance to "open" position momentarily, then slowly decrease (turn out all) resistance. Regulator should again be operating on upper set of contacts. Note voltmeter reading and the ambient temperature (temperature of air surrounding regulator ¼" from its cover) Operating voltage should be as indicated in ambient temperature table below.

Operation on Lower Contacts - Increase resistance slowly until voltage regulator begins to operate on lower contacts. Lower set of contacts should operate .1-.3 volts lower than upper contacts.

Adjustment of Voltage Setting - (Upper set of Contacts). Turn adjusting screw clockwise to increase voltage and counterclockwise to decrease voltage *CAUTION* - If adjusting screw is turned down beyond range, spring support may not return when screw is backed off. In this case, turn screw counterclockwise until there is ample clearance between screw head and spring support Then bend spring support up carefully until it touches screw head. Final setting of unit should be made by increasing spring tension. If setting is too high, adjust unit below required value, then raise to exact value by increasing spring tension. After each adjustment, and before taking reading, replace regulator cover and recycle generator

Lower Set of Contacts - Adjust for difference in voltage (1- 3 volts lower) between operation of upper set of contacts and the lower set by increasing or decreasing air gap between armature and center of core. Increase voltage by increasing air gap or decrease voltage by decreasing air gap. Loosen armature screw slightly, than insert screw-driver in slot of bracket and move armature up or down as necessary Lower points should just be touching when air gap is checked. Recheck voltage setting for both sets of contacts.

1958-60 DELCO-REMY "1119600 SERIES" "DOUBLE CONTACT" REGULATORS (C ntinued)

CURRENT REGULATOR

Air Gap: .075" with contacts just touching. Check and adjust gap in same manner as for Voltage Regulator above.

Curr nt S tting: *NOTE - Current regulator must be brought up to normal op rating temperature before checking curr nt's tting. On "T mperature Compensated" curr nt r gulators (see tabl below), the "Ambient Temp rature" must b d t rmined and the regulator set to th current value indicated in "Current Setting - Ambi nt Temp ratur " table* Connect ammeter in charging circuit at regulator "BAT" terminal (in series with battery) Turn on all accessory load (lights, radio, etc) and connect additional load (bank of lights or carbon pile rheostat) to reduce voltage to approximately 1.0 volt below regulator setting Operate generator at a speed sufficient to produce current in excess of specified setting for 15 minutes (with cover in place) to bring regulator up to normal operating temperature. *NOTE - On "Non-temperature Compensated" regulators it is not necessary to bring the regulator to operating temperature.* Cycle the generator by turning the variable resistance to the "open" position momentarily then slowly decrease (turn out all) resistance and note ammeter reading which will be the regulator setting *NOTE - Voltage regulator should be operating on upper set of contacts.* To adjust, turn adjusting screw at current regulator armature spring lower bracket clockwise to increase setting or counter-clockwise to decrease setting

FORD MOTOR CO. 6-VOLT REGULATORS

►CHANGES, CAUTIONS, CORRECTIONS

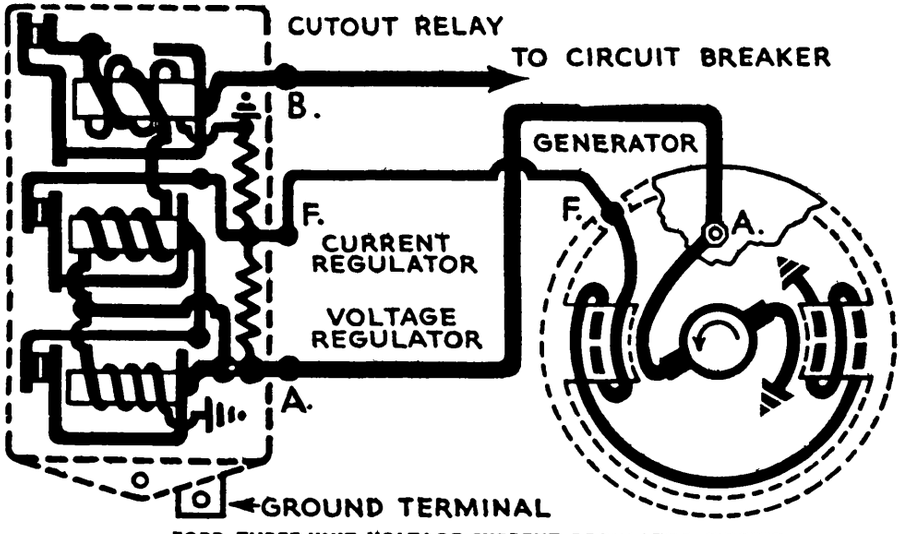
►**REPLACEMENT GENERATOR NOTE:** FAA-10002-A or B production generators replace generator 8BA-10002-A, 8BA-10002-B, 8BA-10002-D

►**REGULATOR & GENERATOR GROUND CAUTION:** Regulator and generator grounds must be in place when units operated (regulator may be grounded through mounting screw or separate ground lead). See car page wiring diagram for data.

DESCRIPTION

DESCRIPTION: 3 unit (Cutout Relay, Voltage Regulator, Current Regulator) regulator with separate voltage and current regulator units (these units were combined on previous 2-unit regulators). Regulators are vibrating type and charging rate is normally controlled by Voltage Regulator. Current Regulator operates when current reaches value in excess of rated capacity and limits current to this figure. Both regulators operate in the same manner by cutting the resistance in and out of the field circuit and control the generator output by regulating the field current

►*CAUTION*—Ford Generators and Ford Regulators are not wired in the same manner as units of other makes and cannot be operated in conjunction with units of other makes. Always operate Ford Generators & Regulators together.



CHECKING & ADJUSTING REGULATOR

CHECKING & ADJUSTMENT OF REGULATOR: Use special test set (with an adjustable field rheostat—see Ford Test Note below). If separate test meters are used to check performance, a variable field rheostat should be used so that generator output can be varied when making tests.

Ford Test Note—Ford Test Set has a variable field rheostat (connected between regulator "F" terminal and generator field lead) and a ¾ ohm fixed resistance through which the generator charges (resistor and ammeter connected in series to regulator "B" terminal while regular charging line is disconnected from this terminal) and a carbon-pile rheostat (in parallel with the ¾ ohm fixed resistance) which can be cut in to the circuit by a push button to provide sufficient load to enable current regulator to be adjusted (carbon-pile rheostat is variable and resistance should be slowly decreased until current regulator operates). This enables all tests to be made with generator operating at 1500 RPM.

►*NOTE*—Regulator should be at normal operating temperature when checking regulator settings.

►*CAUTION*—Ground connection must be in place when generator and regulator are operated. If ground wire disturbed by removal of regulator cover,

FORD THREE-UNIT VOLTAGE-CURRENT REGULATOR CIRCUIT

make certain that regulator and generator are both grounded whenever these units are being operated.

REGULATOR SETTINGS

Relay Cut-in Voltage—Connect ammeter in charging line at regulator "BAT" terminal (disconnect lead at this terminal, connect one ammeter lead to this lead, connect other ammeter lead to terminal). Connect voltmeter between regulator "ARM" terminal and ground on regulator base. Connect jumper wire between generator "A" and "F" terminals Start engine and slowly increase speed until relay contacts close, note voltmeter reading (pointer will drop back slightly at this point). Cut-in voltage should be within limits shown in table below. To adjust, remove regulator cover, bend support at lower end of relay

CONTINUED ON NEXT PAGE

FORD MOTOR CO.
6-VOLT REGULATORS (C nt.)

armature spring in to increase tension and raise cut-in voltage, bend support out to decrease tension and lower cut-in voltage.

Relay Cut-out Reverse Current—After checking cut-in voltage above, increase engine speed until generator charges at approximately 10 amperes, then slowly decrease engine speed and note reverse or discharge current reading on ammeter at instant relay contacts open. If this reverse current not within limits shown in table below, check relay air gap and armature stop setting (see Specifications below).

Cutout Relay Settings

Regulator Type	Cut-in Voltage	Cut-out Reverse Current
5EH-10505-C	6.6-7.0 volts	0-8 amperes
51A-10505-A1	6.6-7.0 volts	0-8 amperes
51A-10505-A2, B2, C2, D2	6.0-6.3 volts (Cold)	0-8 amperes
51A-10505-H, J	6.6-7.0 volts	0-8 amperes
8A-10505-A	6.0-6.6 volts	0-8 amperes
8L-10505	6.0-6.6 volts	0-8 amperes
8M-10505-A	6.0-6.6 volts	0-8 amperes
FAC-10505-A,A1,A2	6.0-6.6 volts	0-8 amperes
FAD-10505-A	6.0-6.6 volts	0-8 amperes
FAE-10505-A	6.0-6.6 volts	0-8 amperes
FAJ-10505	6.0-6.6 volts	0-8 amperes

►***IDLE SPEED NOTE***—**If higher than cut-in point, it will be necessary to back off throttle stopscrew and bring idling speed below cut-in point.**

Voltage Regulator Setting—Check with the cover in place and at 70-80°F. with the regulator at normal operating temperature (after operating for 30 minutes or having been heated on the test bench so temperature stabilized). Connect ammeter in charging line at regulator "BAT" terminal (disconnect lead on this terminal, connect ammeter to this lead and to the terminal), connect voltmeter between regulator "ARM" terminal and ground. Run engine at 1500 RPM., adjust charging rate to 8-10 amperes (if less than 8 amperes, turn on lights or other load; if more than 12 amperes, cut in resistance of the test set). Note voltmeter reading with generator output of 8-10 amperes (CAUTION —cover must be in place when making this reading). To adjust, remove regulator cover, bend spring adjustment (bending arm—see illustration) upward to increase spring tension and voltage setting, or down to decrease spring tension and voltage setting. Re-install cover and repeat test.

►***CAUTION***—**Voltage will drop approx. 0.2 volt when steel cover installed and should be allowed for when adjusting (aluminum covers do not change setting).**

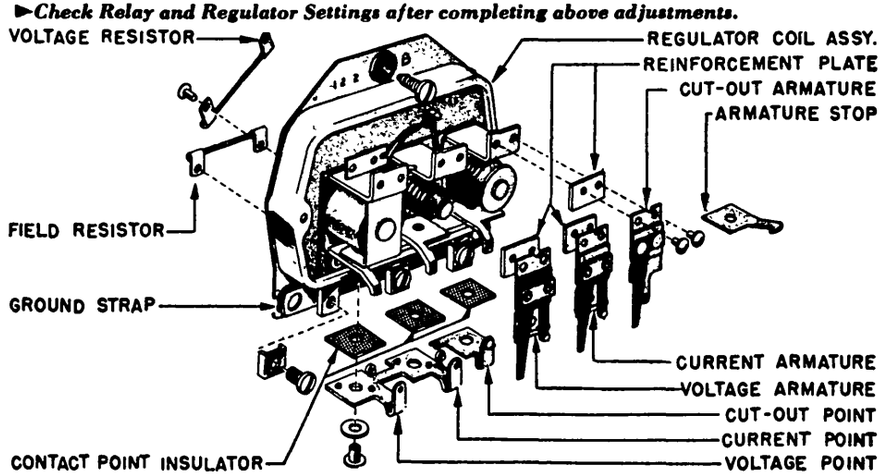
Voltage Regulator Setting

Regulator Type	Setting (Volts)
5EH-10505-C	②7.2-7.6
51A-10505-A1 (Std. & Trop.)	7.2-7.6
51A-10505-A2, C2 (Std.)	①7.0-7.3
51A-10505-B2, D2 (Trop.)	①6.8-7.3
51A-10505-H (Std.)	7.2-7.6
51A-10505-J (Trop.)	7.0-7.4
8A-10505-A (Std.)	②7.2-7.6
8L-10505 (Std.)	②7.2-7.6
8M-10505-A (Std.)	②7.2-7.6
FAC-10505-A,A1,A2	③7.4-7.8
FAD-10505-A	③7.4-7.8
FAE-10505-A	③7.2-7.6
FAJ-10505	③7.1-7.3

①—Cold setting.
②—7.0-7.4 volts with regulator COLD.
③—With Ambient air temperature from 70 to 80°F.

Current Regulator Setting—After checking Voltage Regulator (above) reinstall regulator cover if removed. Proceed as for voltage regulator check with engine running at 1500 RPM. (approx. 30 MPH.), use Battery-Starter Tester to increase load (or decrease resistance of carbon-pile regulator on Ford Test Set), note ammeter reading which should agree with current regulator setting below. To adjust, remove regulator cover, bend spring adjustment (bending arm—see illustration) upward to increase spring tension and current setting, or down to decrease spring tension and current setting.

Current Regulator Setting



Regulator Type	Setting (Amperes)
5EH-10505-C	38-42
51A-10505-A1	30-34
51A-10505-A2, B2, C2, D2	30-33
51A-10505-H, J	34-38
8A-10505-A	30-34
8L-10505	38-42
8M-10505-A	34-38
FAC-10505-A,A1,A2	34-38
FAD-10505-A	38-42
FAJ-10505	48-52

►***CAUTION***—After tests completed, disconnect test meters, connect charging line to regulator "BAT" terminal. **Make certain that jumper removed from generator "A" and "F" terminals.**

REGULATOR SPECIFICATIONS

Cutout Relay Contact Gap—.010" with armature against stop.
Cutout Relay Air Gap—.014" between armature and core with contacts open.
Contact Gap and Air Gap Setting—Insert .014" feeler between armature and core. Then set contact gap to .010" using a feeler gauge, by lowering armature stop and raising the lower contact, tighten 2 lower contact screws.
►***CAUTION***—Heel of armature must not touch relay frame.
Aligning Cutout Relay Contacts—Contacts must make and break squarely. If adjustment necessary, bend lower contact up or down, then check Air Gap and Contact Gap (may be disturbed by movement of lower contact).
Regulator Air Gap—.032-.035" between armature and core (contacts closed).
Setting Air Gap—Bend the spring adjustment (bending arm)—see illustration —to clear armature spring. Insert .035" gauge (round stock) between armature and core (*CAUTION*—On voltage regulator make certain gauge does not contact rivet on underside of armature). Press armature down, turn contact screw down to just touch armature contact, set contact screw with locknut. Realign contacts
Regulator Contact Spring Tension—5 ozs. minimum with contacts just opening.
Checking Contact Spring Tension—Use a spring scale to measure tension just as contacts open. Adjust upper contact screw after loosening locknut if pressure below limits listed above.

►***Check Relay and Regulator Settings after completing above adjustments.***

REGULATOR CONTACT ASSY.

FORD MOTOR CO. 12-VOLT REGULATORS

►CAUTIONS

►*GENERATOR POLARIZING: (NOTE* - Polarization is not necessary except when generator has been rebuilt or if new pole shoes have been installed). To polarize a generator on the car, disconnect the field wire and the battery wire from the regulator and momentarily connect the two wires together (engine not running). *CAUTION - Do not polarize generator by any method that applies battery voltage to field terminal of regulator.*

►*NORMALIZING THE REGULATOR:* **On the Car**—Clip special thermometer T56L-10505-A on regulator cover (see Note below). Operate engine with generator charging at 10 ampere rate for 30 minutes or until regulator temperature is stabilized.

On the Bench—Procedure is same as on the car except that a small fan should be mounted 12-15" from the regulator so as to circulate air over the regulator cover while it is being warmed up.

Thermometer T56L-10505-A Note—This thermometer is calibrated in 10°F. increments and has additional Voltage scales indicating the correct voltage regulator setting for each temperature reading (both 6 volt and 12 volt scales provided).

►*AMBIENT TEMPERATURE NOTE:* Ambient temperature is the temperature taken adjacent to the regulator, using Thermometer T56L-10505-A.

DESCRIPTION: These 12 volt regulators are the same design as previous 12 volt units.

CHECKING & ADJUSTMENT: *CAUTION*—Regulators are temperature-compensated and must be brought up to normal operating temperature before checks are made. This normal temperature is that existing adjacent to the regulator cover after 1/2 hour of operation in the car or after the regulator has been heated until the temperature is stabilized (standard normal temperature is 70-80°F.

►*TEST METER CONNECTIONS:* If special Test Sets used, make all connections in accordance with manufacturer's instructions. If individual meters used, make connections as follows: Connect test ammeter and 1½ ohm fixed resistor in series in charging line at regulator "BAT" terminal, from regulator terminal to ground (Ford). *CAUTION - Disconnect battery cable.* On other cars, connect test ammeter and 1½ ohm fixed resistor in series in charging line at regulator "BAT" terminal in series with battery. Connect voltmeter between regulator "ARM" terminal and ground (regulator base or battery grounded terminal). Connect a 50 ohm variable field rheostat (2 amp. rating) in generator field circuit (disconnect field lead at regulator "FIELD" terminal, connect rheostat between this lead and regulator "FIELD" terminal).

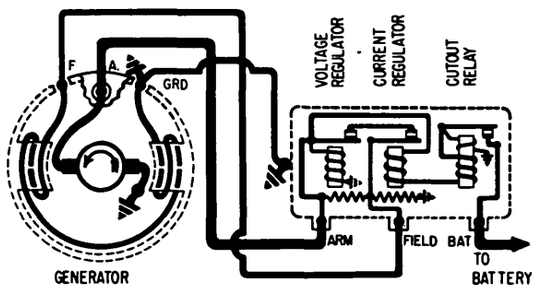
CUTOUT RELAY

Cut-In (Closing) Voltage: After regulator normalized and with test meters connected (see above), check cut-in voltage as follows:

Comet, Falcon, Ford - With field resistance completely turned in the field circuit, operate engine at 1500 RPM, slowly turn resistance out of field circuit and note voltmeter reading when relay contacts close (pointer will drop back slightly). Repeat this check several times by turning resistance in and out of field circuit.

Edsel, Lincoln, Mercury - With resistance turned out of field circuit, slowly increase generator speed and note voltmeter reading at instant relay contacts close (pointer will drop back slightly). Repeat this check several times by decreasing generator speed until contacts open and then increasing speed until contacts close. If closing voltage not correct as shown in setting table below, adjustment is required.

Adjustment - Bend adjusting arm under armature spring (to left of relay contacts) upward to increase cut-in voltage, or downward to decrease cut-in voltage. Replace regulator cover and recheck the setting.



Cut-In (Closing) Voltage Setting

All (Exc. 40 Amp. Auto-Lite) - 12.0-12.8 volts.
40 Amp. Auto-Lite - 12.5-13.9 volts.

Cut-out (Opening) Discharge Current: This can be checked after checking cut-in voltage by increasing generator speed (or turning out field resistance) until charging current is approximately 10 amperes, then slowly decrease generator speed (or turn in field resistance) until maximum **discharge** current indicated on ammeter (ammeter will return to zero as contacts open)

Cut-Out (Opening) Discharge Current

All (Exc. 40 Amp. Auto-Lite) - 5-9 amperes.
40 Amp. Auto-Lite - 2-6 amperes.

12-VOLT REGULATOR WIRING DIAGRAM

VOLTAGE REGULATOR

Voltage Setting: After Cutout Relay checked (above), cycle regulator by decreasing generator speed until cutout relay contacts open and then increase speed to 1500 RPM. Clip special thermometer on regulator cover to establish regulator ambient temperature and corresponding voltage setting (see Voltage Regulator Settings for various ambient temperatures below). Turn resistance completely out of field circuit (charging rate should be approximately 10 amperes). Note voltmeter reading. This is the voltage setting and should agree with setting listed below.

Final Test (Ford) - Remove all test leads except voltmeter leads and install "BAT" and "F" wires on regulator. Run engine at 1500 RPM (under battery load) and note voltmeter reading (voltage will rise to regulated value after a few moments operation).

Adjustment—Bend adjusting arm under armature spring (to left of regulator contacts) upward to increase voltage setting, or downward to decrease voltage setting. Replace regulator cover and recheck the setting after each adjustment.

Voltage Setting

All (Exc. 40 Amp. Auto-Lite) - 14.6-15.4 volts, with ambient air temperature of 70-80°F. *See table below.*
40 Amp. Auto-Lite - 14.2-14.9 volts with ambient air temperature of 70-80°F. *See table below.*

Ford Voltage Regulator Settings (Ambient Temperature Correction)

Ambient Temp. (°F)	All Exc. Auto-Lite 40 Amp. (Volts)	Auto-Lite 40 Amp. (Volts)
25°	15.1-15.9	14.3-15.2
35°	15.0-15.8	14.3-15.2
45°	14.9-15.7	14.3-15.1
55°	14.8-15.6	14.3-15.0
65°	14.7-15.5	14.3-14.9
75°	14.6-15.4	14.2-14.9
85°	14.5-15.3	14.1-14.8
95°	14.3-15.1	14.1-14.7
105°	14.2-15.0	14.0-14.7
115°	14.1-14.9	14.0-14.6
125°	13.9-14.7	13.9-14.5
135°	13.8-14.6	13.8-14.4
145°	13.6-14.4	13.8-14.4

CURRENT REGULATOR

Current Setting: This check requires that a load be added, or that the generator voltage be dropped to approximately 13 volts, to cause current regulator to operate. It is recommended that a heavy duty variable resistance (carbon pile) be connected across the 1-1/2 ohm fixed resistor in the charging line (connect resistance from ammeter lead terminal of fixed resistor to ground—see Test Meter Connections above). After Voltage Regulator checked (above), and with all resistance turned out of the field circuit, operate generator at 1500 RPM (Comet, Falcon, Ford), 2000 RPM (Continental, Lincoln, Mercury), decrease the resistance until voltage drops to approximately 13 volts and ammeter reading is at maximum. This ammeter reading is the current setting. If not correct (see table below), adjust as follows:

Adjustment—Bend adjusting arm under armature spring (to left of regulator contacts) upward to increase current setting, or downward to decrease current setting. Replace regulator cover and recheck setting.

Current Setting

30 Amp. Regulator - 28-32 amperes (all models).
35 Amp. Regulator - 33-37 amperes (all models).
40 Amp. Regulator - 38-42 amperes (all models).

AUTOLITE STARTERS

DESCRIPTION: Four pole, four brush starters of conventional design. Some starters have brush holders riveted to starter frame, on other starters, brush holder and brush assembly is screwed to frame or commutator endplate. Starters are of various "shunt" and "no shunt" designs as listed below. *See individual Car Model pages and Car Model wiring diagrams for starter application and internal wiring.*

Starter Model	Volts	Series Coils	Shunt Coils
MCL	6	4	0
MCH	6	2	0
MZ	6 & 12	4	0
MBG, MDB, MDC, MDD	12	4	0
MDF, MDG, MDL	12	3	1
MDM, MDT, MDY	12	3	1
MDU, MEC	12	2	1

TESTING: Free Running Test – Connect an ammeter and carbon pile rheostat in series with battery positive post and starter terminal. Connect a voltmeter across starter. With all resistance turned into circuit, connect battery negative post to starter frame. Adjust rheostat to obtain proper voltage and note current draw and starter RPM. *See Car Model pages for specifications.* Current draw and starter RPM should be as specified. *CAUTION – On starters with shunt coils, DO NOT operate on "No Load" longer than necessary for test as shunt coil produces more force than series coils under this condition and pulls armature toward shunt coil with possible damage to bearings and other parts.*

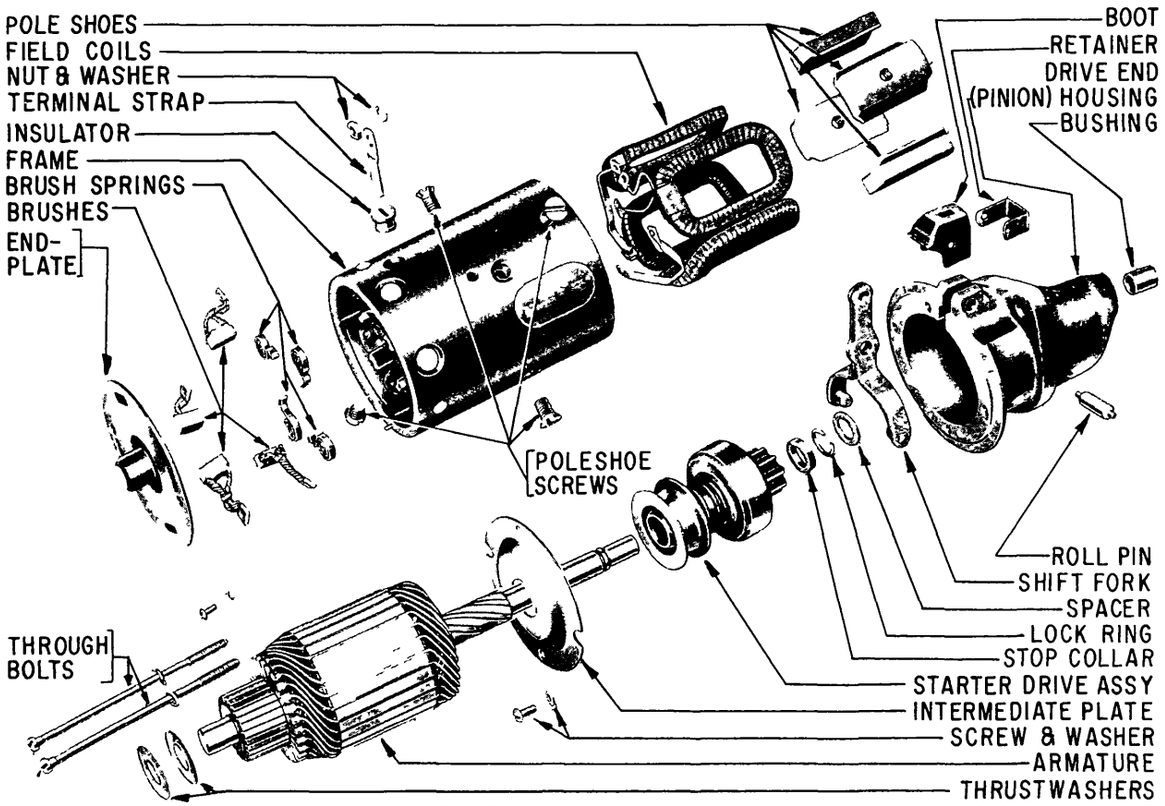
Stall Torque Test: Mount starter in a test stand and follow test equipment manufacturer's instructions. Torque, volt, and ampere readings should be as specified. *See Car Model pages for specifications.*

OVERHAUL: Disassembly – Remove solenoid and cover band if equipped. Remove commutator endplate. Remove brushes from brush holders in endplate or frame. Remove drive housing-to-frame attaching screws and remove housing and armature assembly from frame. Remove intermediate bearing plate attaching screws and separate armature and drive assembly from housing. Remove drive assembly from armature shaft depending on method of attachment as follows: **1)** Remove lock ring and push spring plate toward drive pinion to expose setscrew. Remove setscrew and remove drive assembly. Remove key and remove intermediate bearing plate from shaft. **2)** Rotate barrel of drive away from armature to expose hole in worm section of shaft, then rotate barrel in opposite direction to expose roll pin. Drive out roll pin and remove drive unit. **3)** Slide pinion gear toward commutator end of shaft, drive the stop collar toward pinion, remove lock ring and remove drive assembly.

Inspection – DO NOT immerse parts in solvent. Wipe parts with a clean cloth only. Check for wear, distortion, evidence of burning, etc.

Armature: Check for shorted armature with a growler. Check for ground to shaft with a test lamp. Armature shaft runout should not exceed .003". Commutator runout should not exceed .003". Reface commutator if necessary and undercut mica segments 1/32". Polish commutator with No. 00 sandpaper.

Field Coils & Frame: *NOTE – On starters with a shunt field coil, disconnect ground lead from shunt coil before making tests.* If brush holders mounted in starter frame, check insulated brush holders for ground. Check series coils for grounds and shunt coil for continuity or internal ground. Check shunt coil current draw. Specifications should be as in table below. When replacing field coils, an impact screwdriver such as C-3475 is recommended to seat and tighten pole pieces properly and to prevent damage. Long tip of pole shoe should be installed as the trailing edge. Check insulated terminal for ground with frame.



Shunt Field Current Draw

Starter	Amperes	Volts
MDF, MDL, MDT, MDY	8.2–9.6	10.0
MDM, MDU, MEC	4.4–5.1	10.0

Brushes: Replace brushes if oil soaked or worn to less than ½ original length (compare with new brushes). Check brush spring tension as follows:

MCL, MCH, MBG, MDB, MDC, MDF, MDG, MZ – Hook spring scale under spring near brush or at bend in spring just beyond brush. Pull scale straight up and note reading just as spring leaves brush. *See Car Model pages for specifications.*

MDL, MDM, MDT, MDU, MDY, MEC – Hook spring scale under brush screw. Pull scale straight up and note reading just as brush leaves commutator. *See Car Model pages for specifications.*

TYPICAL AUTOLITE STARTER ASSEMBLY (EXPLODED)

Endplate & Bushings: If brush holders mounted in endplate, check insulated holders for ground with endplate. Check bushings for wear, roughness, and for proper fit. Drive end bushing clearance with shaft should be .001–.006". Commutator end bushing clearance with shaft should be .001–.005". Replace bushings, endplates, or pinion housing as necessary.

Reassembly: Reverse disassembly procedures and note the following special points:

Air Gap (Armature-to-Field Coils) – .042–.060" (MCL, MCH), .026–.048" (MBG, MZ).

Oil Felt – Felt oil pad must be in outer end of commutator end bearing before assembling endplate to frame.

Armature Shaft Endplay – .005" minimum. On Positive Pinion Shift types .030" maximum, except .062" maximum on MBG & MCL with Bendix Drive. Endplay adjusted by thrust washers between bearing shoulder on armature shaft and either end bearing as necessary to keep brushes centered on commutator.

Drive End Bushing – Must be flush with bearing bore on outer end (except MDF 6010 & MDG 6003, 6004 on inner end).

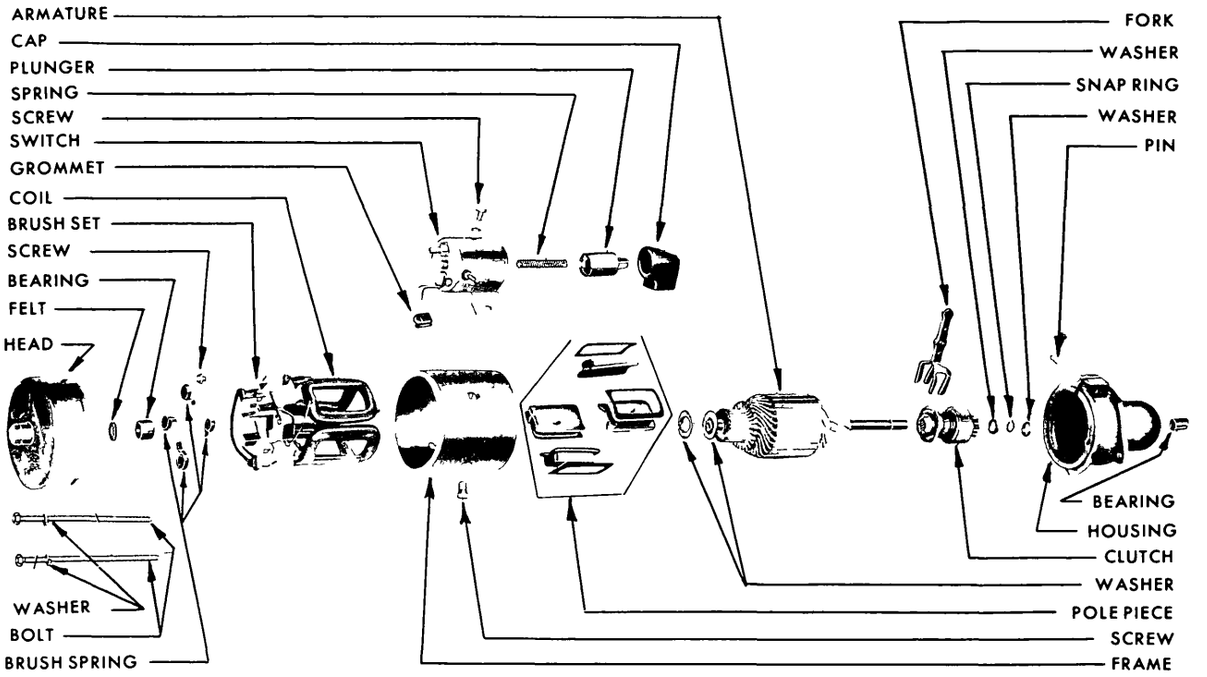
Outer Pinion Housing Bushing – Must be flush with bearing bore on inside of housing.

STARTER CONTROL: *See "Starter Controls" in this section.*

CHRYSLER CORP. STARTERS

Car Model	Chrysler Part No.
Chrysler & DeSoto (1960-61)	1889200
Dodge & Plymouth 361" Eng (1961)	1889200
Dodge & Plymouth 318" Eng (1961)	1889100

DESCRIPTION: 12 volt, four-pole type with solenoid pinion shift (overrunning clutch) Brushes and springs are mounted in a separate removable brush holder plate assembly



SPECIFICATIONS: **Rotation** - Counterclockwise at commutator end
Brush Spring Tension - 32-48 ozs
Driv Endplay - 005" minimum
Pinion to Housing Clearance - 1/8"±1/32" measured between pinion and pinion stop (with armature endplay removed)
Performance Data: *See Car Model pages*

REPLACEMENT: **Brushes & Springs** - *NOTE - Brushes that are worn to ¼" or less or are oil soaked, should be replaced* With commutator end head, brushes and brush holder removed, unsolder the two leads at ground brush terminal and the two insulated brush leads at field coil terminal (adjacent to hole in front face of field frame which is used in locating brush holder ring assembly) *CAUTION - Use care in removing and installing ground brush s so that shunt wire is not broken* To remove brush springs, spread retainer tabs apart slightly on brush holder ring If new springs are installed pinch the retainer tabs together, if necessary, to hold springs securely Measure brush spring tension with starting motor completely assembled except for end head Measure spring tension with spring scale hooked under spring near the end Pull scale straight back while holding brush against commutator Take a reading just as spring end loses contact with the brush Spring tension should be 32-48 ounces

►*TESTING & OVERHAUL NOTE All testing and service procedures are the same as for conventional starters except as noted below*

TESTING: **Field Coils** - With commutator end head, brushes and brush holder ring removed, disconnect field lead wires at solenoid connector and separate field leads to make sure they do not touch solenoid connector Remove wire attaching ground terminal to field frame and pull brush leads, shunt wire and terminal assembly aside so there will be no contact
1) Touch one prod of test lamp to series field coil lead, and the other prod to field frame Lamp should **not** light
2) Touch one prod to shunt field coil lead and other prod to field frame If lamp lights in either of the two above tests, field coils are grounded and each coil should be tested separately after unsoldering the connecting wires
3) Test two insulated brush holders for proper insulation from ring assembly by touching one test light prod to brush holder and the other to the ring The lamp should not light If lamp lights, the insulated brush holders are grounded and the brush ring assembly must be replaced

OVERHAUL: **Disassembly** - Remove through bolts at commutator end and pull head from frame Remove thrust washers from armature shaft, then lift brush holder spring and remove brushes Remove brush holder plate Disconnect field coil leads at solenoid connector, then remove solenoid attaching screws and remove solenoid and boot assembly Drive out overrunning clutch shift fork pivot pin at upper side of pinion housing, then remove drive end pinion housing and spacer washer Note position of shifter fork on starter drive and remove shifter fork Slide overrunning clutch pinion gear toward commutator end of armature Drive stop retainer toward pinion gear to expose snap ring and remove snap ring Remove overrunning clutch drive from armature shaft *NOTE - If it is necessary to remove field coils, remove ground brush terminal attaching screw and raise brushes with terminal and shunt wires up and away from field frame* Remove pole shoe screws with special impact screwdriver, Tool C-3475

CHRYSLER CORP. STARTER MOTOR (EXPLODED)

Cleaning: Wipe field frame, coil assembly and armature with a clean cloth only To clean drive unit, use a brush moistened in solvent DO NOT immerse starter parts in cleaning solvent

Reassembly: Lubricate armature shaft and splines with SAE 10-W oil or 30-W rust preventive oil, then install starter drive, stop collar (retainer), lock ring and spacer washer *NOTE - Small diameter end of spacer washer should be in contact with lock ring inside collar.* Install shifting fork over starter drive spring retainer washer with narrow leg of fork toward commutator *CAUTION - If fork is not properly positioned, it will restrict starter gear travel, causing a lockup in the clutch* Install drive end pinion housing on armature shaft, indexing shifter fork with slot in housing, then install shifter fork pivot Pin Install solenoid and boot assembly on field frame and tighten screws to 60-70 inch pounds Install pinion housing and armature assembly into field frame so slot in housing indexes with locating tab projecting from solenoid base *NOTE - Make sure shifting fork lever is inserted in solenoid plunger link* Connect field coil leads at solenoid connector, then connect ground brushes and shunt wire terminal to field frame Install brush holder ring assembly, indexing tang on ring in hole in field frame Install brushes in brush holders *CAUTION - Make sure field coil lead wires are properly enclosed behind brush holder ring and do not interfere with brush operation* Position thrust washer on end of armature shaft and install commutator end head Install through bolts and tighten to 40-50 inch pounds

ADJUSTMENT: **Starter Drive Gear** - Place starter assembly in a vise with soft jaws, then push in on forward end of solenoid plunger link (not shifting fork lever) until plunger bottoms Measure clearance between end of pinion and pinion stop with plunger seated and pinion pushed toward commutator end Clearance should be 1/8"±1/32" Adjust for proper clearance by loosening solenoid attaching screws and moving solenoid in slotted holes in base *NOTE - In some cases it may be necessary to remove starter end head and bend the end of the solenoid connector slightly to obtain proper adjustment*

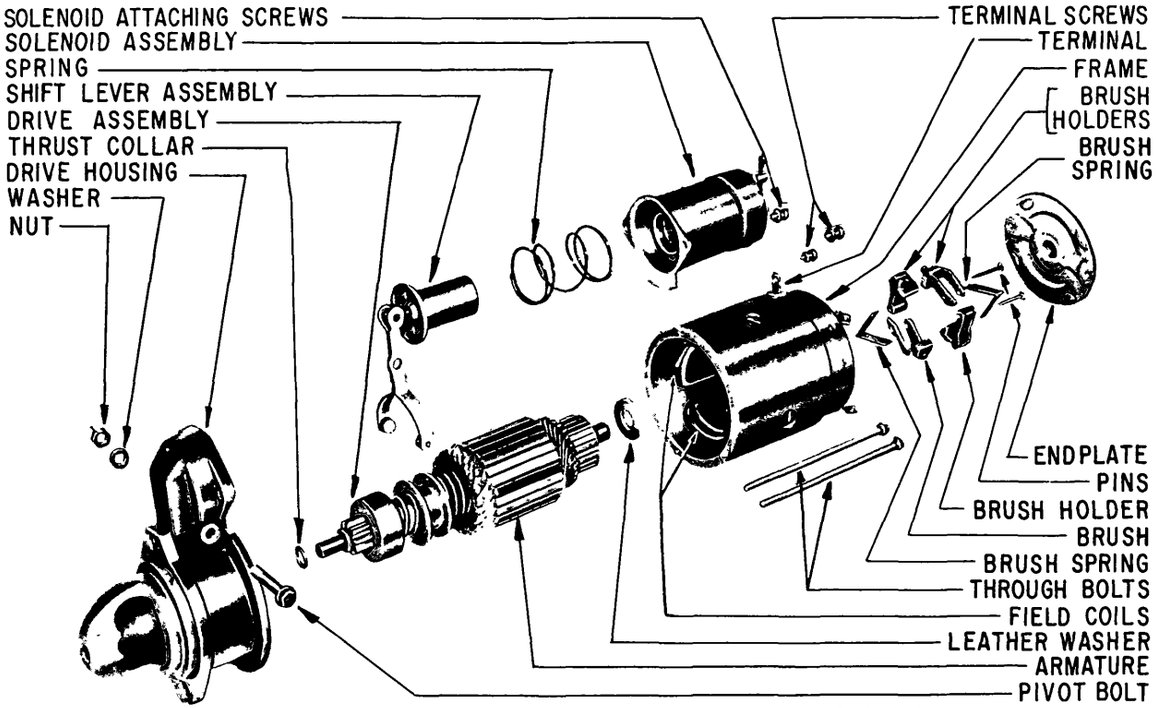
SOLENOID SWITCH: Test Specifications -
Pull-In Coil - 20 0-22 2 Amps at 6 0 Volts at 70°F
Hold-In Coil - 11 2-12 4 Amps at 6 0 Volts at 70°F

DELCO-REMY STARTERS

DESCRIPTION: Four pole, four brush starters of conventional design. Starters are of various two coil or four coil (with or without shunt coils) designs. *See individual Car Model pages and Car Model wiring diagrams for starter application and internal wiring.*

TESTING: *NOTE – On starters with "Enclosed Housing" solenoid unit, make tests with solenoid attached to starter. On other units, remove solenoid before making tests.*

Fr e Running Test: Connect an ammeter and carbon pile rheostat in series with battery and starter terminal or solenoid "BAT" terminal (Enclosed Housing type). Connect a voltmeter across starter and a tachometer to indicate starter armature RPM. Energize starter by connecting other battery terminal to starter frame or solenoid winding terminal. Adjust rheostat to give specified voltage on voltmeter and note ampere and RPM readings. Current draw and starter RPM should be as specified. *See Car Model pages for specifications.*



Stall Torque Test: With ammeter, rheostat, and voltmeter connections as in "Free Running Test" above, lock armature (Enclosed Housing type), install a 12" brake arm on drive pinion and hook it to a spring scale held at right angle to brake arm (others). At specified voltage, current draw and torque should be as specified. *See Car Model pages for specifications.*

OVERHAUL: Disassembly (Not Enclosed Housing Type) – Remove solenoid by disconnecting solenoid from plunger linkage and from starter terminal and then removing attaching screws. Remove through bolts and remove commutator endplate assembly and field frame assembly from drive housing. Remove large shift lever retainer clip, unhook and remove shift lever spring. Remove small retainer clip and upper shift lever shaft. Remove armature assembly with lower shift lever from drive housing. Remove drive assembly from armature by removing thrust collar from shaft and driving retainer off snap ring (toward armature windings), then remove snap ring, retainer, and drive assembly.

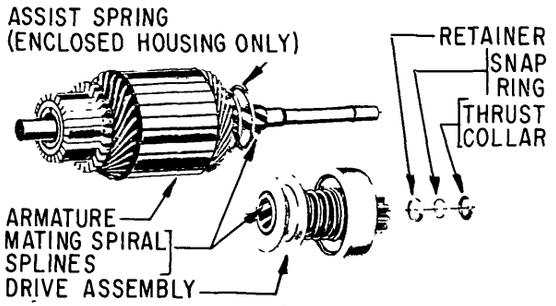
Disassembly (Enclosed Housing Type): Disconnect field strap from solenoid terminal. Remove through bolts and remove commutator endplate, field frame, and armature assembly from drive housing and solenoid assembly. Separate commutator endplate, field frame, and armature assemblies. Remove thrust collar from armature shaft, press retainer off snap ring (toward armature windings), remove snap ring, retainer, drive assembly, and assist spring from armature shaft.

Cl aning (All Types) – DO NOT use a grease–dissolving type solvent. Clean or wipe all parts with oleum spirits and brush or cloth. Wipe drive assembly with a clean cloth only.

Armature (All Typ s): With a 110–volt test lamp check for open circuit between commutator and armature winding, and for ground to armature shaft from armature laminations. Check for armature short circuits with a growler. Check commutator for out-of-round, or if worn or dirty. Reface commutator as necessary, removing as little metal as possible. Undercut mica segments 1/32" deep and square entire length of slot. Polish commutator with No. 00 sandpaper.

DELCO-REMY "ENCLOSED HOUSING" STARTER ASSEMBLY (EXPLODED)

Field Coils & Frame (All Types): With a 110–volt test lamp check field coils for grounds or open circuit. *NOTE – On shunt coil type starters, disconnect shunt coil from ground before making above tests.* Replace field coils as necessary. *NOTE – Pole Shoe Screwdriver and Pole Shoe Spreader are recommended to replace field coils.* Make sure that long lip of pole shoe is installed so that long lip is in direction of armature rotation and becomes trailing edge of shoe. Check brush holders for bent or deformed condition. With a 110–volt test lamp, check insulated brush holders for ground with frame.



Brushes (All Types): Check brushes for wear, or if dirty and oil soaked, and for free fit in holders. Replace brushes if worn more than ½ original length (compare with new brushes). Check brush spring tension. *See Car Model pages for specifications.*

Bushings (All Types): Armature shaft should fit snugly into bushings. Replace bushings or endplate if clearance excessive, or if worn or grooved.

Reassembly (Not Enclosed Housing Type): Assemble drive assembly to armature as follows: Lubricate armature shaft with light oil and slide drive assembly on shaft with pinion outward. Install retainer on shaft with cupped side toward end of shaft. Place commutator end of shaft on a wood block and place snap ring on shaft and hold in place with another wood block. Hit block with hammer to force snap ring over shaft and then slide snap ring into shaft groove. Place thrust collar on shaft next to snap ring and squeeze retainer and thrust collar together with two pairs of pliers until retainer is forced over snap ring. Complete reassembly by reversing disassembly procedures and placing 4 or 5 drops of light oil in bushings.

Reassembly (Enclosed Housing Type): Assemble drive assembly to armature as detailed under "Reassembly (Not Enclosed Housing Type)" above. Reverse disassembly procedures, making sure leather washer is installed on commutator end of armature shaft, and placing 4 or 5 drops of light oil in bushings.

STARTER CONTROL: *See "Starter Controls" in this section.*

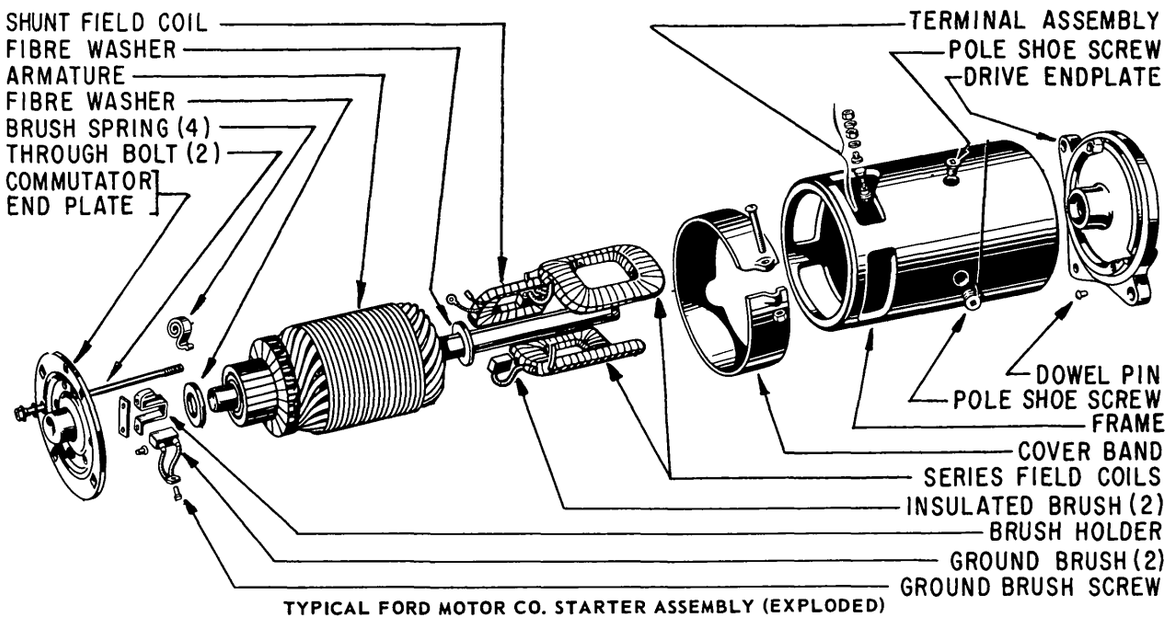
STARTER ARMATURE & DRIVE ASSEMBLY

Form 47 A

EDSEL, FORD, LINCOLN MERCURY STARTERS

DESCRIPTION: Four pole, four brush starters of conventional design. Two coil, no shunt, and three coil, one shunt types are used. *See individual Car Model pages and Car Model wiring diagrams for starter application and internal wiring.*

TESTING: Cranking Test – Connect an ammeter and carbon pile rheostat across battery with **all** resistance turned into circuit. Connect a voltmeter across battery. Crank engine for **15 seconds** (prevent engine from firing by grounding coil primary terminal) and note voltmeter reading at end of 15 seconds. Stop cranking. Adjust carbon pile rheostat until voltmeter reading is the same as when engine was cranked. Ammeter reading should be as specified. *See Car Model pages for specifications.*



Free Running Test: Method 1 – With engine idling, connect ammeter positive lead to battery ungrounded post and negative ammeter lead to starter terminal of starter relay if test made on car. If test made off car, connect ammeter negative lead to starter terminal, positive ammeter lead to battery positive post, and negative battery post to starter frame. Starter will run at no load. Current draw on ammeter should be as specified. *See Car Model pages for specifications.*

Method 2 – Connect an ammeter and carbon pile rheostat across battery with **all** resistance turned into circuit. Connect a voltmeter across battery. Start engine and hold in "start" position so starter drive pinion remains engaged with flywheel. With engine at idling speed, note voltmeter reading. Stop engine. Adjust carbon pile rheostat so that voltmeter reading is the same as when engine was running. Ammeter reading should be as specified. *See Car Model pages for specifications.*

OVERHAUL: Disassembly – Remove drive assembly from armature shaft by pushing spring toward pinion and removing retaining pin. Remove starter cover band and remove brushes. Remove through bolts, endplates, and armature from starter frame.

Cleaning – Wipe field coils and armature with a clean cloth. Wash all other parts except brushes in solvent.

Armature: Inspect armature windings for broken or burned insulation and unsoldered connections. With a 110–volt test lamp, check for open circuit between commutator and armature windings. Check armature for grounds or short circuits with a growler. Commutator runout should not exceed .002". Reface commutator if necessary, removing as little metal as possible. Polish commutator with No. 00 sandpaper. *NOTE – Unnecessary to undercut mica segments.* Check armature shaft bearing surfaces for scoring or excessive wear.

TYPICAL FORD MOTOR CO. STARTER ASSEMBLY (EXPLODED)

Field Windings & Frame: With a 110–volt test lamp, check field coils for continuity and for short circuit to starter frame. *NOTE – Disconnect shunt coil ground lead at frame before making tests.* Check starter field terminal for ground with frame. When replacing field coils it is recommended that Tool 10044-A be used with an arbor press to hold tool in screw socket and to assure proper installation. When tightening pole shoe screws, strike frame several times with a soft hammer to seat and align pole shoes.

Brushes: Replace brushes if dirty, oil soaked or worn to 5/16" in length. Brushes must slide freely in brush holders. Check brush spring tension. *See Car Model pages for specifications.*

Endplates: Replace endplates if cracked or damaged. Check bushings for wear or scoring. Replace bushings or endplates if bushings worn excessively. Check for ground between insulated brush holders and commutator endplate. Replace endplate if ground exists or if insulation is poor.

Reassembly: Install commutator endplate (with brush springs installed) on starter frame with locating pin on frame in slot in endplate. Install fibre washer on each end of armature shaft and install armature into frame and commutator endplate assembly. Install drive endplate. Install and tighten through bolts. Install brushes, making sure they are free in their holders under spring tension. Install cover band, making sure cutout in band clears field terminal. Lubricate drive end of armature shaft with light graphite oil and install drive assembly.

COMET & FALCON STARTER & STARTER CONTOL

DESCRIPTION: Four pole, four brush starter with three series coils and one shunt coil. Shunt coil is wound around a movable pole piece which operates the integral positive engagement drive mechanism. *See individual Car Model pages and Car Model wiring diagrams for starter application and internal wiring.*

OPERATION: With ignition key in start position, current flowing through starter motor drive coil to ground creates a strong magnetic field in drive coil which causes the movable pole (part of drive unit lever) to be drawn downward to its seat, moving the lever assembly fork to slide drive gear pinion into engagement with engine flywheel *NOTE - When seated, the movable pole functions as a normal field pole and the drive coil functions as a field coil* An extension of the movable pole lever opens the contacts allowing equal flow of current through all field coils causing the armature to rotate *NOTE - Drive pinion gear is engaged to flywheel before motor is energized* A holding coil in the circuit retains drive unit in engaged position and the contacts open, when, due to overrunning conditions, field current may not be sufficient to maintain control of movable pole With ignition key released, starter drive actuating lever and movable pole are released by lever return spring and drive pinion is disengaged from flywheel

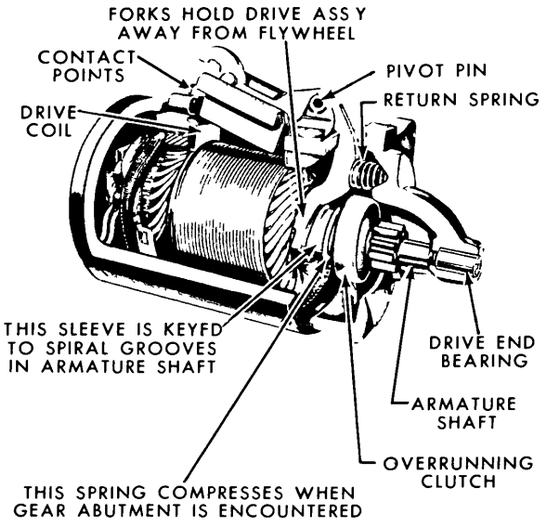
TESTING: Cranking Test – Connect an ammeter and carbon pile rheostat across battery with **all** resistance turned into circuit. Connect a voltmeter across battery. Crank engine for **15 seconds** (prevent engine from firing by grounding coil primary terminal) and note voltmeter reading at end of 15 seconds. Stop cranking. Adjust carbon pile rheostat until voltmeter reading is the same as when engine was cranked. Ammeter reading should be as specified. *See Car Model pages for specifications.*

Free Running Test: Connect a voltmeter across a **fully charged** battery. Connect ammeter positive lead to battery positive post, and negative ammeter lead to starter terminal. Connect battery negative post to starter frame. Starter will run at no load. Ammeter and voltmeter readings should be as specified. *See Car Model pages for specifications.*

CONTINUED ON NEXT PAGE

COMET & FALCON STARTER & STARTER CONTOL (C nt.)

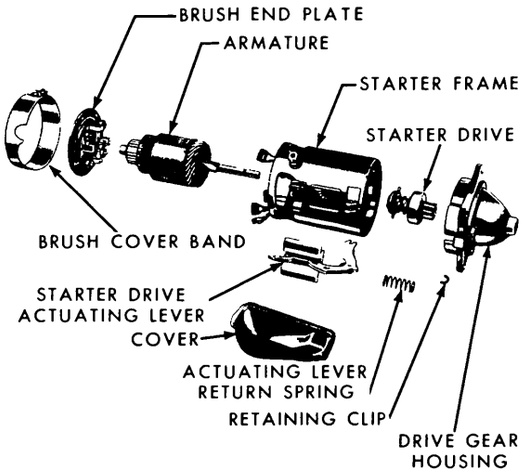
OVERHAUL: Disass mbly — Remove cover band and starter drive actuating lever cover. Re move the through bolts, drive end housing, and drive actuating lever return spring. Remove actuating lever pivot pin and remove actuating lever and pole piece assembly. Remove brushes from brush holders. Use a hooked tool to lift brush springs and remove commutator endpl ate. Remove armature. Remove starter drive retaining clip from end of armature shaft and remove starter drive gear assembly. Remove upper and lower ground brush retaining screws and remove lower brush. Separate holding coil terminal from upper ground brush.



Cleaning — Wipe coils, armature and shaft with a clean cloth. Wash all other parts except brushes in solvent.

Armature: Check armature shaft bearing surfaces for wear or scoring. With a 110–volt test lamp, check armature for short circuit to shaft and for open circuits between commutator segments. With a growler, check for shorted armature windings. Check commutator for burning, rough surface or out-of-round condition. Run-out should not exceed .002". Reface commutator as necessary, removing no more than 3/64" of commutator diameter. Polish commutator with No. 00 sandpaper. *NOTE – Unnecessary to undercut mica segments.* Make sure starter drive operates freely on armature shaft.

Field Coil Assembly: Testing — Check solder connections and insulation for good condition. Test field coils for short circuit to frame. *CAUTION – Block drive coil contact assembly (on top of starter) open with a wood block or cardboard to prevent grounding of field circuit. Also make sure field coil brushes and holding coil terminal are clear of frame.* Check holding coil for continuity with one test probe on holding coil terminal and other test probe on drive coil terminal. Test lamp should light.



►*TOOL NOTE:* Use Tool 10044-A in a vise or arbor press to hold tool in screw when removing and installing pole shoes. Use of tool will also insure proper tightening of pole shoe screws.

Removal — Remove pole shoes and unsolder field coil leads from terminal screw and from ground contact point plate. *NOTE – Small holding coil lead is soldered to contact plate with drive coil lead and is disconnected at the same time.* Remove drive coil retaining sleeve from frame by collapsing both sides of sleeve and removing from inside frame. Pull field coil assembly from frame. To remove contact assembly, drive attaching rivet from frame from the inside and disassemble the contacts. Remove starter terminal assembly.

STARTER & CONTROL ASSEMBLY

Installation — Thoroughly clean starter frame. Install terminal screw assembly with screw slot perpendicular to frame end surface, but **do not** tighten nut. Install contacts to frame by placing a 5/40 pan head screw in rivet hole in frame with screw head on inside of frame. Place lower contact, insulator cord, upper contact, and insulator washer in position. Install a 5/40 nut on screw, tighten nut and stake screw. Install field coil assembly in frame with drive-holding coil at movable pole opening. Place drive coil upper short lead and lead from opposite coil into contact plate slot. Also place small holding coil lead into contact plate slot. Place drive coil side long lead and adjacent coil long lead into starter terminal screw slot. Install fixed pole shoes and strike frame with soft hammer as screws are tightened to seat and align shoes. Place drive coil retainer flange on retainer sleeve and, from inside frame, install sleeve into drive coil and frame openings. Install armature in frame and press it firmly against sleeve retainer by wedging small screwdrivers between each end of armature and lower pole. Lock coil to frame by bending outer protruding parts of retainer sleeve over frame. Remove armature. Place movable pole in retainer sleeve and tap pole sideways to align sleeve. Remove movable pole. Solder coil leads to contact point plate and to terminal screw. *CAUTION – Small holding coil uninsulated lead must be soldered to contact plate and routed to avoid shorting to frame.* Tighten terminal screw nut. Test assembly for grounds with frame (see above).

STARTER ASSEMBLY (EXPLODED)

Brushes: Replace brushes if dirty or oil soaked or if worn to 5/16" in length.

Bushings & Endplates: If bushings are worn excessively or scored, replace bushings, commutator endplate, or drive end housing as necessary. Check insulated brush holders for ground with endplate. Check for broken brush springs and check brush spring tension. *See Car Model pages for specifications.*

Reassembly: Attach holding coil ground terminal to frame with upper ground brush. Attach lower ground brush to frame. Apply light film of high grade snythetic silicone grease to armature bearing surfaces and spiral teeth. Install drive assembly to armature shaft with a new retaining clip. Install armature and movable pole assembly together, making sure that actuating lever forks engage ears of drive assembly plate. Install and lubricate actuating lever pivot pin (pin retained by lever cover). Place steel washer on armature shaft drive end and leather washer on shaft commutator end. Pull brushes out through frame openings nearest assembled position. Place commutator endplate and through bolts and commutator endplate locating dowel in frame. Install drive actuating lever return spring and drive end housing and install and tighten through bolts. *CAUTION – Do not pinch brush leads between brush plate and frame.* Install brushes in brush holders with brush springs centered on brushes. Install drive gear actuating lever cover and frame cover band.

BARREL TYPE BENDIX

See Starter Drive listing on individual car model pages for type used.

DESCRIPTION: This drive retains Bendix inertia principle of engagement and free longitudinal movement to insure pinion mesh but has been redesigned so that all parts of drive mechanism except drive spring are located within the pinion barrel. The threaded sleeve is mounted loosely on an extension of the drive head (instead of directly on the starter shaft) and is retained by the stop nut which is screwed and staked in place on the outer end of the head. The pinion is integral with the barrel or drive sleeve and is mounted loosely on the starter shaft (not on threaded sleeve as in former types). Starter drive is through lugs on the control nut or driving ring on the screw shaft which engage slots in the end of the pinion barrel. Pinion barrel is held in place on control nut by a locking ring within the end of the barrel directly behind the driving lugs. A coil type anti-drift spring is mounted on the threaded sleeve ahead of the control nut and a meshing spring is located within the head of the barrel

BENDIX SPRINGS: Both Type "F" and "H" driving springs formed with special smaller diameter end coil designed to fit closely on shaft at ends. No spring clips used with these types. Springs may be identified by larger (⅜") spring eye. Spring eyes located on same side of coil (Type F), or 180° apart (Type H).

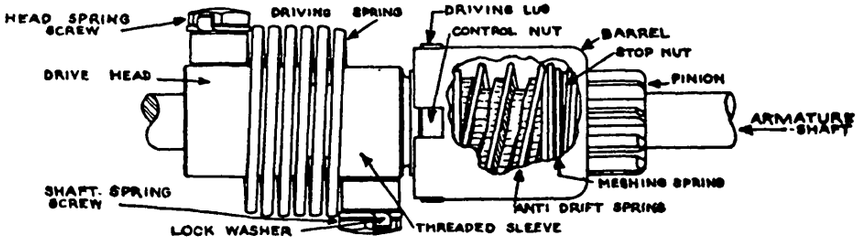
OPERATION: Pinion, barrel, and control nut operate as a unit and pinion is moved out into mesh with the flywheel as the control nut is threaded along the threaded sleeve. If the pinion teeth strike the ends of the flywheel teeth, the free longitudinal movement of the threaded sleeve on the drive head allows the pinion to turn slightly and mesh properly. This free movement important to insure correct meshing and prevent jammed pinion or damage to gear teeth.

SERVICING: No servicing required except cleaning and oiling of threaded sleeve and armature shaft under pinion when operation not satisfactory.

Armature Shaft:—Rotate pinion back to demeshed position, clean exposed portion of shaft with kerosene, lubricate lightly (Gredag 31¼ graphite grease).

Threaded Sleeve:—Rotate pinion forward to meshed position as far as possible, wipe threads clean with dry cloth or use kerosene sparingly (not gasoline). Do not wash entire drive in kerosene or grease installed under threaded sleeve at time of assembly will be removed (threaded sleeve cannot be removed to replace this lubricant). Lubricate threaded sleeve lightly with 10-W engine oil.

TROUBLE SHOOTING: If pinion jams or meshes improperly, check as follows:



(1) Armature shaft rough or burred, dirty or rusty under threaded sleeve (first type only). Remove Bendix, clean and smooth shaft, lubricate shaft lightly with graphite grease Gredag 31¼ before replacing drive.

(2) Armature shaft rough, burred or dirty under Bendix pinion (all types). Thread pinion back on threaded sleeve (demeshed position), smooth shaft with emery cloth or clean with kerosene (do not use gasoline), lubricate shaft lightly with Gredag 31¼ graphite grease.

(3) Armature Shaft Bent. Remove Bendix drive. Check shaft and straighten

(4) Drive spring screw at threaded sleeve end too long. See that spring does not project through sleeve and bind on drive head extension (on first type screw will bind on armature shaft).

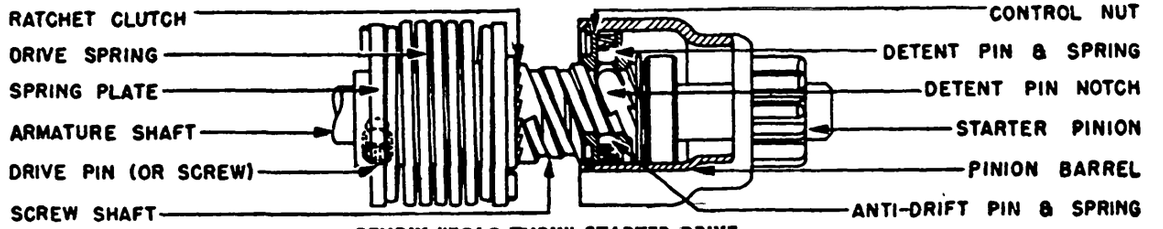
(5) Cocked or deformed drive spring. This will cause threaded sleeve to drag on armature shaft (first type) or on drive head extension (later types). Remove spring by taking out spring screws, examine spring, replace if necessary. Spring eye centers should be at right angles to spring axis (See Spring Note above). Use new lockwashers under spring screw heads when replacing screws and see that one lip of washer is turned down in spring eye gap and other lip turned up against screw head flat.

BARREL TYPE (SPRING SCREW TYPE) BENDIX DRIVE

BENDIX "FOLO-THRU" STARTER DRIVE

DESCRIPTION & OPERATION: The "Folo-Thru" Bendix Drive is similar to other Bendix Barrel-Anchor Plate types and operates in the same manner except for the Detent Pin action which prevents premature demeshing of the pinion from the flywheel ring gear as follows:

Detent Pin Operation—The detent pin consists of a spring-loaded plunger in the Control Nut which drops into notch in the screwshaft when the pinion is in the fully engaged position. The pin cannot be disengaged or the pinion moved manually from the engaged position and will only release when the pinion speed reaches 5800-7300 RPM. (at this point, centrifugal force moves the pin outward to free the pinion) and the pinion then is free to disengage from the flywheel ring gear. A ratchet clutch on the screwshaft (between the pinion and the drive spring) allows the pinion to overrun the starter armature shaft and prevents damage to the starter when the pinion is being driven by the engine. *NOTE*—An Anti-drift Spring (similar in appearance to the Detent Pin) is also located in the Control Nut. This anti-drift pin rides on the teeth of the screwshaft and prevents accidental engagement of the pinion due to vibration while the engine is running.



SERVICING: *Do not disassemble this drive* (furnished only as a complete unit due to calibration requirements of Detent and Anti-Drift Pin Springs). Service is limited to removal and installation of the drive or to cleaning when necessary (if drive fails to operate due to gummy deposit of oil or dirt).

Cleaning the Drive: Dip screwshaft and pinion assembly in clean kerosene or use brush to apply kerosene, run pinion back and forth on threads to remove all gum and grit, dry the drive with compressed air. No lubrication is recommended although a very light film of SAE 10W engine oil can be used on moving parts if desired. *CAUTION—Too much oil on screwshaft will collect dust and produce a gummy condition which will interfere with drive operation.*

REMOVAL: To remove drive assembly from armature shaft, push spring plate toward drive pinion to expose the setscrew or pin mounting the drive on the armature shaft. Remove this screw or pin, slide drive off shaft. Do not disassemble the drive.

INSTALLATION: *CAUTION—Drive cannot be moved manually from engaged to disengaged position, however drive can be installed on starter and starter installed on engine with drive in the engaged position.* Slide drive assembly on armature shaft and align mounting screw hole in screwshaft with hole in armature shaft, compress spring plate and insert mounting screw or pin. Install starter on engine.

►*CAUTION*—If drive in "Engaged" position, make certain that pinion properly engaged in flywheel ring gear teeth and that starter seated solidly on its mounting flange before mounting screws are tightened. DO NOT FORCE STARTER INTO PLACE (will cause misalignment and binding of pinion teeth or drive).

BENDIX "FOLO-THRU" STARTER DRIVE

AUTOLITE MANUAL PINION SHIFT STARTER SWITCHES

►***PINION STOP & RETAINING RING WEAR & BREAKAGE (MCH-6106, MCH-6110, MCL-6110, MCL-6111 Starters with MCH-2070 Armature):*** On early starters noted above, failure of the starter may be caused by pinion stop and retaining ring moving on armature shaft. Correct by installing new armature (with hardened shaft) and new retaining ring and pinion stop which have reduced clearances in shaft groove. ***CAUTION***—"Pinion clearance when engaged" setting should be carefully adjusted to limits shown in ADJUSTMENTS below to prevent pounding of the stop when the pinion is engaged.

DESCRIPTION & OPERATION: Manually operated pinion shift and starting switch assembly with switch mounted on the starter field frame. Shift lever is linked to starting pedal on toeboard and is operated by depressing the pedal. First movement of the lever meshes the pinion with the flywheel ring gear and the switch is then closed by a lug on the lever (if pinion teeth butt against flywheel teeth, a spring permits further movement of the lever to close the switch, and the pinion is meshed by the spring as the armature starts to turn). An overrunning clutch in the starter drive prevents starter being driven at excessive speed when the engine begins to fire (pinion is demeshed by the return spring as soon as the pedal is released).

ADJUSTMENT: Check the following specifications and adjust as required:

Pinion Position when Disengaged: With starter at rest, the distance from the outer face of the pinion housing (face of starter mounting flange) to outer face of the pinion is shown in table below.

Pinion Position (Disengaged)

Starter Model	①Pinion Distance	Starter Model	①Pinion Distance
MAW (All Models)	1 11/32"	MCH (All Models)	1.317-1.467"
MAX (exc. MAW-4009)	1 11/32"	MCL (All Models)	1.317-1.467"
MAX-4009 only	See Note	MZ (Exc. MZ-4137, 4162)	1 11/32"
		MZ-4137 & 4162	25/32"

①—Variation of Plus 1/64" or Minus 5/32" is allowable.

MZ-4101 Note—With pinion at rest, distance from center of locating dowel hole to face of pinion should be 3½" with ⅛" clearance between pinion and flywheel. Pinion travel between at rest and fully meshed positions should be ½".

MAX-4009 Note—With pinion at rest, distance from center of locating dowel hole to outer face of pinion should be 2 11/32" plus 1/64" or minus 5/32".

Pinion Clearance when Engaged: With shift lever at end of the travel, clearance between outer face of pinion and thrust washer next to outer pinion bearing is shown in table below. Adjust by pressing down on spring on switch plunger and turning button on outer end of plunger in or out. The button is locked by the end of the spring.

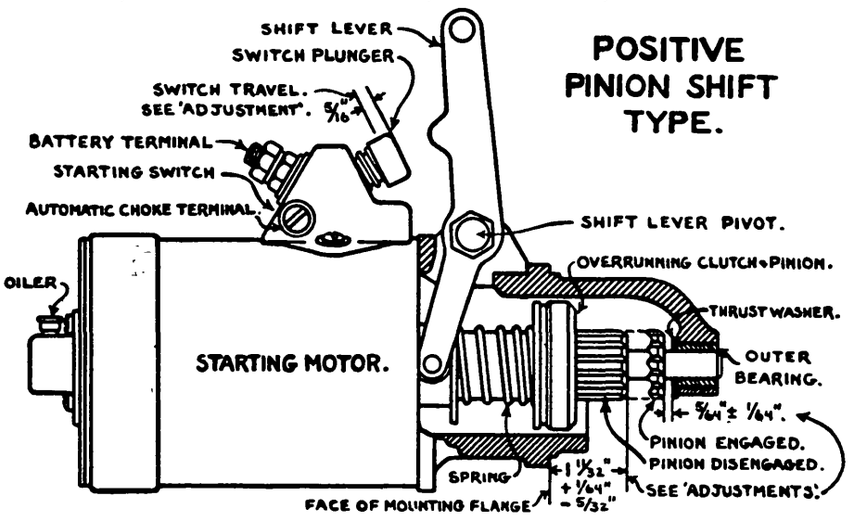
Pinion Clearance (Engaged)

Starter Model	①Pinion Clearance	Starter Model	①Pinion Clearance
MAW (All Models)	5/64"	MCL-6110, F, T; 6111, T	3/32"
MAX (All Models)	5/64"	MCL-6112	5/64"
MCH-6103	5/64"	MCL-6126	3/32"
MCH-6106, F, T; 6110	3/32"	MZ (Exc. MZ-4137, 4162)	5/64"
MCL-6102, 6103	5/64"	MZ-4137, 4162	37/64"

①—Variation of plus or minus 1/64" is allowable.

Switch Travel: The full stroke or travel of the switch plunger should be approximately 5/32" (All MAW & MAX Starters, All MZ Starters except MZ-4137 & 4162), 3/16" (MZ-4137 & 4162), 3/16" (All MCH & MCL Starters). See pinion clearance data above.

MAW-4019 & 4019A Note—Tension required to move yoke lever into contact with starting switch button should be 9-15 lbs. at hole 3 3/16" from yoke pin.



Checking Switch Action: Switch action can be checked by slipping a special steel spacer (square stock 1" wide, ¾" thick, with ⅝" slot in the 1" face) on armature shaft between pinion and thrust washer at pinion housing outer bearing. With spacer in place, switch should close when pressure applied to outer end of pinion shift lever.

MCH-6106, F, T; 6110 Note—When checking switch action on these models, use spacer block ½" thick instead of regular ¾" thick block mentioned above.

MCL-6110. F, T; 6111, T; 6126 Note—When checking switch action on these models, use spacer block ½" thick instead of regular ¾" thick block mentioned above.

MZ-4101 Note—When checking switch action on this model, use spacer bl ck ⅜" thick instead of regular ¾" thick block mentioned above.

Armature Endplay: The armature endplay should be .005" minimum, .030" maximum. Adjust by inserting MU-54 thrust washer of correct thickness between the MAD-96 thrust washer and the commutator end plate. These thrust washers furnished in following thicknesses: MU-54 or MU-54F—1/32", MU-54A or MU-54G—1/64", MU-54B or MU-54J—3/64", MU-54L—1/16", MU-54K—5/64".

AUTOLITE MAGNETIC STARTER SWITCHES

DESCRIPTION: Magnetic solenoid switches of conventional design mounted on the starter field frame and controlled by a pushbutton switch on the instrument panel. The feed wire for the switch solenoid is connected to the coil side of the ignition switch so that the starter is operative only with the ignition turned on. See car diagrams for wiring and connections of each installation.

OPERATION: Two springs are used in connection with solenoid coil to control the switch action. When the solenoid circuit is completed by pressing the pushbutton switch, the solenoid plunger is drawn into the coil against the tension of a light spring. After the main switch contacts close, the plunger compresses a second spring, insuring a positive connection at the switch contacts. When the pushbutton switch is released, breaking the solenoid circuit, this second spring quickly separates the main switch contacts, preventing arcing or burning of the contacts. The first spring then returns the solenoid plunger to the off position.

CHECKING & ADJUSTMENT: If switch does not operate satisfactorily, check performance specifications as given below. No adjustments are required in service.

PERFORMANCE SPECIFICATIONS:	6 Volt Types	12 Volt Types
Closing Voltage	3.0-4.0 volts	6.0-8.5 volts
Opening Voltage	0.5-1.25 volts	1.0-2.5 volts
Coil Draw (at 77°F)	①2.6-3.3 amperes	②1.43-1.62 amperes
Voltage Drop (with 100 amperes)	0.20 volts max.	0.20 volts max.

①—At 6.0 volts. ②—At 12.0 volts.

AUTOLITE SOLENOID STARTER SWITCH (NO RELAY)

DESCRIPTION: This combined starting switch and pinion shift solenoid is similar to earlier types except that no solenoid relay is used.

OPERATION: Solenoid has two windings: (1) Series winding or "pull-in" coil, (2) Shunt winding or "hold-in" coil. Both windings are energized to engage the starter pinion with the flywheel and to close the main starting switch contacts. Series winding is short-circuited when the switch contacts close but shunt winding remains energized to hold contacts closed.

ADJUSTMENT: Pinion position when disengaged (at rest) and pinion clearance when engaged should be checked and adjusted as follows:

Pinion Position when Disengaged—Measure distance from face of mounting flange to outer face or edge of pinion in the "at rest" position with the armature end clearance taken up first in one direction and then in the opposite direction.

Pinion Position (Disengaged)

Starter Model	Pinion Position
MCH 6113, 6113A	1 5/16-1 15/32"
MCL 6117, 6121A, 6133, 6304	1 5/16-1 15/32"
MCL 6132	53/64-63/64"
MDB 6001	1.317-1.467"
MDC (All)	1.317-1.476"
MDF 6008	53/64-63/64"

MEC 6001	23/32-7/8"
MEC 6002	41/64-51/64"

Pinion Clearance when Engaged—With the plunger bottomed in the core (see Note below) and with the armature endplay taken up at the commutator end, measure clearance between outer face or edge of pinion and pinion stop. If not correct, adjust by screwing the solenoid plunger or adjusting pin in or out as required after removing the pin linking the shift lever and the plunger link.

NOTE—Plunger can be bottomed in coil for above check by pressing in on plunger by hand (CAUTION—do not press on shift lever or pinion) or by disconnecting strap connector to starter terminal so that starter will not spin and then connecting battery to solenoid terminal and ground on starter field frame (coil will hold plunger in while adjustment being made).

Pinion Clearance (Engaged)

Starter Model	Clearance
MCH, MDB	3/32"±1/64"
MCL MDC, MDF, MDL	3/32"+1/32" - 1/64"
MDT, MDU, MDY, MEC	3/32"+1/32" - 1/64"

Starter Armature Endplay—.005" minimum, .030" maximum. Adjust by installing MU-54 thrustwashers on armature shaft at commutator end plate (between the MCH-96 thrustwasher and the end plate).

PERFORMANCE: Current draw is as follows:

SOLENOID CURRENT DRAW

Series SSX (All)

Pull-in Coil - 31.5-36.0 amps. at 3.0 volts.
Hold-in Coil - 8.8-10.1 amps. at 3.0 volts.

Series SAD (All)

Pull-in Coil - 28.6-32.9 amps. at 6.0 volts.
Hold-in Coil - 10.2-11.8 amps. at 6.0 volts.

Series SAJ (All)

Pull-in Coil - 19.9-23.0 amps. at 6.0 volts.
Hold-in Coil - 10.0-11.6 amps. at 6 0 volts.

Series SSY (All)

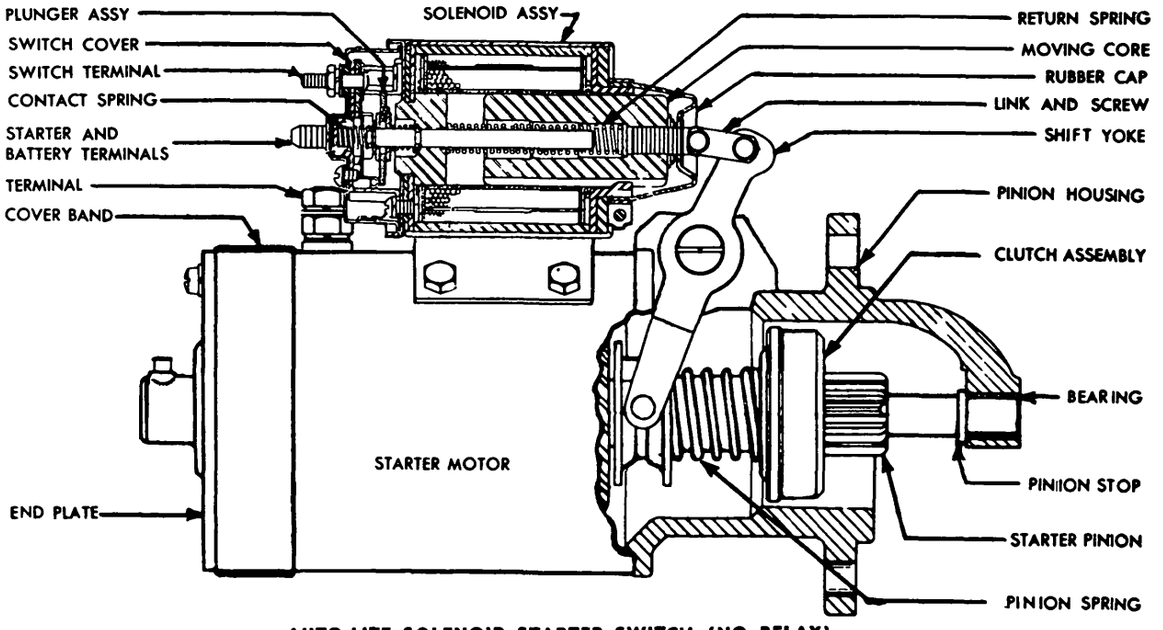
Pull-in Coil -17.0-19.4 amps. at 6.0 volts.
Hold-in Coil - 4.8-5.5 amps. at 6.0 volts.

CONTROL RELAY SPECIFICATIONS

Series HRW (6 Volt)

Contact Closing Voltage - 1.5-3.0 volts.
Armature Seals to Core - 4.0 volts (maximum).
Contact Opening Voltage - 0.5 volts (minimum).
Contact Gap - .020-.040". Adjust by bending armature stop up or down.
Armature Air Gap - .012-.020" with contacts closed. Adjust by raising or lowering stationary stop.

Series RAA (12 Volt)



Contact Closing Voltage - 3.0-6.0 Volts (4001); 6.0-8.0 volts (4001A).
Armature Seals to Core - 8.0 volts (maximum).
Contact Opening Voltage - 1.0 volts minimum (4001) 1.0-4.0 volts (4001A).
Contact Gap - .020-.040". Adjust by bending armature stop up or down.
Armature Air Gap - .012-.020". Adjust by raising or lowering stationary stop.

Series RAJ (12 Volt)

Contact Closing Voltage - 6.0-8.0 volts.
Armature Seals to Core - 8.0 volts (maximum).
Contact Opening Voltage - 1.0-4.0 volts.
Contact Gap - .020". Adjust by bending armature stop up or down.
Armature Air Gap - .020-.025" with contacts closed. Adjust by raising or lowering stationary contact.

Series RAM (12 Volt)

Contact Closing Voltage - 5.0-8.0 volts. Adjust by bending hinge ear.
Armature Seals to Core - 8.0 volts (maximum). Adjust by bending hinge ear.
Contact Opening Voltage - 1.0-4.0 volts. Adjust by bending hinge ear
Contact Gap - .020". Adjust by bending armature stop up or down.
Armature Air Gap - .015-.025" with contacts closed. Adjust by raising or lowering stationary contact.

AUTO-LITE SOLENOID STARTER SWITCH (NO RELAY)

DELCO-REMY SOLENOID STARTER SWITCHES (NO RELAY)

DESCRIPTION: This solenoid type combined Starting Switch and Pinion Shift is similar to type used on other cars except that solenoid link is non-adjustable (pinion position adjustable by shifting solenoid assembly on starter) and no relay is incorporated in the solenoid assembly (separate relay used on some cars). 6 Volt and 12 volt units are similar except that special "Ignition Terminal" used on 12 volt units (see Ignition Terminal Note below).

►*IGNITION TERMINAL NOTE (12 Volt Solenoids)*—This special terminal provides an ignition feed which bypasses the ignition coil resistor when the starter is cranking (terminal connected to contact finger in switch which is "live" while switch contacts are closed). See individual car wiring diagrams for ignition coil connections.

►*CONTROL RELAY NOTE: (Buick & Chevrolet Corvette)*—SEPARATE control relay is used in the solenoid control circuit. Relay is not part of solenoid assembly. See CONTROL RELAY data below for specifications and adjustment data. See Individual car wiring diagrams for relay internal circuits and circuit connections.

OPERATION: When the pushbutton is pressed, both solenoid windings are energized (pushbutton is special heavy-duty type designed to handle entire solenoid current). Solenoid plunger is drawn into coil, meshing starter pinion, and closing starting switch contacts (if teeth butt and prevent pinion meshing with flywheel, spring on shaft behind pinion is compressed and meshes the pinion as soon as starter armature shaft begins to rotate). Closing of the starter switch short-circuits the heavy solenoid winding (pull-in coil) and the lighter solenoid winding (hold-in coil) keeps the pinion in mesh until the pushbutton is released when the pinion is withdrawn by the return spring.

►***CAUTION—See special Pinion Clearance Adjustment directions below.***

PERFORMANCE: Solenoid. Current draw below is measured from starter button terminal on solenoid to ground (see illustration). "Both-Coil" specification is with starting switch contacts open, "Hold-in Coil" specification with starting switch contacts closed and pull-in coil short-circuited. If solenoid does not test within limits shown, it should be replaced. *NOTE*—when checking solenoid current draw with solenoid mounted on starter, disconnect solenoid-to-starter connector and ground this solenoid terminal to the solenoid frame. Current draw measured at solenoid control terminal will then be the "Both Coil" draw. Remove the ground wire from the solenoid starter terminal and current will be the "Hold-in Coil" draw.

►***CAUTION—Solenoid should be tested COLD (room temperature of 80°F.).***

SOLENOID CURRENT DRAW

All 6 Volt Types

Both Coils—85-90 amperes, 5 volts, at 80°F.
Hold-in Coil—14-16 amperes, 5 volts, at 80°F.

All 12 Volt Types

Both Coils—72-76 amperes at 10.0 volts.
Hold-in Coil—18-20 amperes at 10.0 volts.

Starter Pinion Overrunning Clutch: Clutch should transmit 50-60 ft.lbs. torque in drive direction without slipping, and should allow pinion to turn freely in overrunning direction.

Shift Lever Return Spring: Check spring tension with spring scale hooked in hole in upper end of shift lever. Pull at start of travel should be 9-12 lbs. and at end of travel should be 28-35 lbs.

ADJUSTMENT: ***CAUTION—It is recommended that starter be removed from engine for adjustment (will provide easier access to solenoid mounting screws).***

Pinion Clearance: *NOTE—Clearance differs for each type starter end thrust device (see identification below) and is the only adjustment required.*

Pinion Clearance—Should be measured from end of pinion to face of drive housing with pinion in operating position. When measuring this clearance, press lightly on outer face of clutch shell to take up all backlash in linkage but DO NOT compress the drive spring.

Pinion Clearance (When Engaged)

Car Model	Thrust Type	Clearance
Buick (1954-56)	③	.010-.050"
Cadillac (1954)	③	.010-.050"
Cadillac (1955-56)	③	.010-.140"
Chevrolet (1954)	①	3/16"±1/32"
Chevrolet (1955-56)	③	.010-.140"
Hudson (1956-57)	③	.010-.140"
Nash (1956-57)	③	.010-.140"
Oldsmobile (1954-56)	③	.010-.140"
Packard (1954-56)	③	.010-.140"
Pontiac (1954)	①	3/16"±1/32"
Rambler (1956-58)	③	.010-.140"

①—Thrust washer on end of armature shaft within pinion housing. Measure clearance between pinion and housing.

③—Thrust washer located within pinion housing and clearance should be measured from face of pinion to this washer.

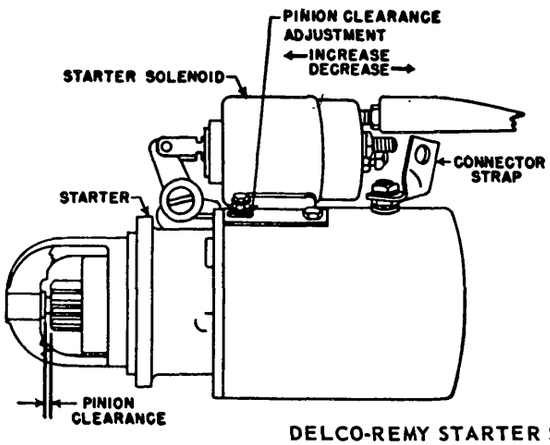
Pinion Clearance Adjustment—Disconnect solenoid to starter strap to prevent motor operating, place a gauge (see Clearance Specifications above) between pinion and housing or between face of pinion and thrust washer as indicated in table above. Connect battery between switch terminal of solenoid and ground (solenoid base) and push plunger in by hand so that pinion is moved out against gauge (battery current will hold solenoid in this position while adjustment is being made). On models without adjustable plunger link, loosen solenoid mounting screws and shift solenoid on starter so that all play in lever and clutch linkage is taken up. Tighten mounting screws. On models with adjustable plunger link, loosen screw and adjust length of link as necessary to remove all play.

►***CAUTION—Do not compress spring on shaft behind overrunning clutch when making above adjustment.***

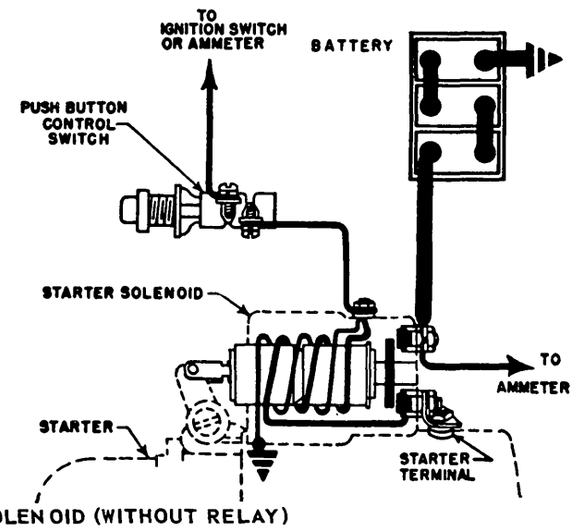
STARTER CONTROL RELAY (BUICK & CHEV. CORVETTE): *CAUTION - Both 6 volt and 12 volt units used. All relays are check d and adjust d alik but specifications are different as list d b low.*

RELAY SPECIFICATIONS

6 Volt No. 1116855



Contact Closing Voltage—1.5-2.1 volts. Armature should "seal" to core at not more than 0.1 volt above closing voltage.



Contact Opening Voltage—Not less than 0.35 volt.

Contact Gap—.025" (.020-.030").

Air Gap—.011" minimum with contacts closed.

CONTINUED ON NEXT PAGE

DELCO-REMY STARTER SOLENOID (WITHOUT RELAY)

DELCO-REMY SOLENOID STARTER SWITCHES (NO RELAY) C ntinu d

6 Volt No. 1116886

Contact Closing Voltage—2.2-3.0. Armature should "seal" to core at not more than .01 volt above closing voltage.

Contact Gap—.025".

Air Gap—.018".

12 Volt No. 1116876 & 1116904

Contact Closing Voltage—3.8-5.0 volts. Armature should "seal" to core at not more than 0.2 volts above closing voltage.

Contact Opening Voltage—Not less than 0.6 volt.

Contact Gap—.025" (.020-.030").

Air Gap—.011" minimum with contacts closed

CHECKING & ADJUSTMENT

Checking Operation—Use rheostat (must have 10 ohm resistance and 2 ampere capacity) and accurate low reading voltmeter. Connect rheostat to relay terminals #1 and #4 (CAUTION—rheostat must be turned to provide full resistance), connect voltmeter to relay terminals #3 and #4. Make certain that ignition switch turned OFF. Slowly decrease resistance by turning rheostat and note voltmeter reading at instant relay contacts close and solenoid switch operates (can be checked by test lamp connected between relay terminal #2 and ground). Voltage reading at this point should agree with "Contact Closing Voltage" in specifications above. Continue to decrease resistance until slight "click" occurs indicating that armature has sealed to the core. Voltage reading at this point should be not more than 0.1 volt higher (6 Volt Relay), 0.2 volt higher (12 Volt Relay) than contact closing voltage. Quickly cut out all resistance to saturate relay magnet core fully, then quickly increase resistance and note voltage reading at instant relay contacts open (if test lamp used, light will go out at this point). Voltage reading at this point should agree with "Contact Opening Voltage" in specifications above.

Relay Adjustment

Contact Closing Voltage—Bend armature spring post **down** (to increase spring tension and closing voltage) or **up** (to decrease spring tension and closing voltage).

Sealing Voltage & Contact Opening Voltage—Adjust by varying air gap (see below) or by changing the closing voltage (CAUTION—closing voltage must be kept within specifications).

Contact Gap—Adjust by bending upper armature stop.

Air Gap—Adjust by bending lower contact support (check air gap by pressing armature down until contacts just touch, then measure between armature and core with feeler gauge).

CHECKING & INSPECTING SOLENOID: If performance not satisfactory, check as follows:

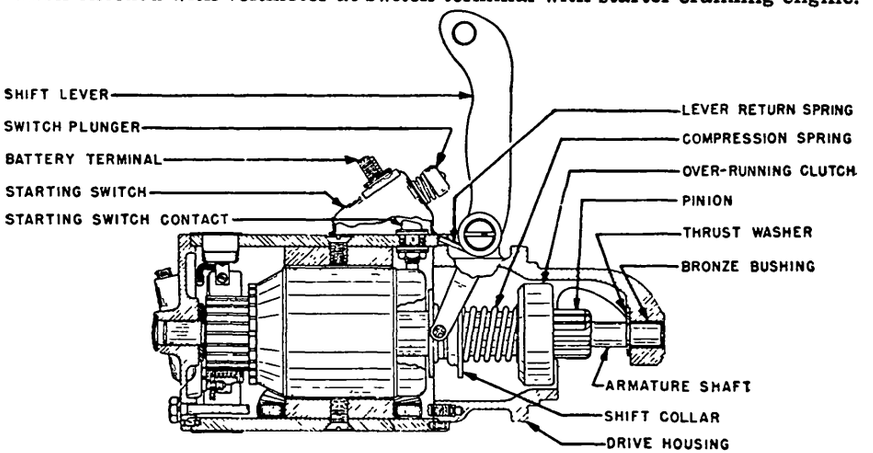
Voltage Drop (High Resistance Check)—Disconnect ammeter lead from battery cable terminal on solenoid, connect voltmeter from battery terminal to starter terminal on solenoid. Use Remote Control Switch connected to pushbutton terminal on solenoid to operate starter motor *(CAUTION*—On 12 volt solenoids with ignition coil terminal, lead must be disconnected from this terminal to prevent engine firing and control switch must NOT be connected to this ignition terminal). Voltage reading with starter cranking must not exceed 0.1 volt (6 volt system). If reading greater, disassemble and inspect solenoid (see below).

Solenoid Inspection—Take out cover retaining screw and remove cover *(CAUTION*—use care not to damage solenoid winding lead. Check solenoid plunger for free movement without binding and see that plunger has sufficient travel for firm contact between the copper contact washer and the starter switch contacts. Make certain that full contact is secured and that contact surfaces are not burned or corroded. *NOTE*—Contacts can be replaced—see OVERHAUL below.

OVERHAUL: Solenoid Contact Replacement: With solenoid removed from starter, remove solenoid plunger from solenoid body. Take out cover retaining screw and remove cover. Remove nuts, lockwashers, flat washers, and insulating washers from each terminal stud. Remove two terminal stud support plate-to-solenoid housing screws, remove support plate, insulating plate, one terminal stud and starter switch stud. Remove outer spring retainer and spring from solenoid plunger contact ring. Compress the contact ring spring, remove retainer, insulating washer, and contact ring from plunger; remove plunger from solenoid body. Unsolder solenoid coil lead from remaining terminal stud.

Reassembly—Place new contact ring and insulating washer on plunger, compress spring and install retainer with open side up *(CAUTION*—Three lugs on bottom of contact ring must index with slots in lower insulating washer). Install solenoid plunger assembly in solenoid body, carefully solder solenoid lead to new terminal stud. Place solenoid plunger spring and outer spring retainer in position over end of solenoid plunger. Place terminal support insulator plate and support plate over the terminal stud soldered to the coil lead *(CAUTION*—Lugs in terminal support plate must fit in holes in insulator). Place starter switch lead stud up through terminal insulator plate, index lugs on stud with slots in insulator plate, snap stud into place. Insert remaining terminal stud up through insulator plate and support plate, install terminal support plate-to-solenoid housing screws (with lockwashers) and tighten screws securely. Install insulating washers, flat washers, lockwashers, and nuts on terminal studs and tighten nuts securely. Install cover and cover attaching screw. Test solenoid for proper operation, install on starter, adjust pinion clearance (see ADJUSTMENT).

DELCO-REMY MANUAL PINION SHIFT STARTER SWITCHES



DESCRIPTION: Starters have a pinion assembly and shift lever similar to that used on Solenoid Pinion Shifts but the shift lever is connected through linkage to the starting pedal so that the pinion is positively engaged with the flywheel teeth when the starting pedal is depressed. The starting switch is mounted on the starter field frame and switch plunger is depressed by lug on shift lever to close switch contacts and operate starter after pinion has been meshed with the flywheel.

SERVICING: No service required and no adjustment provided. Switch contacts should not close until after pinion has been meshed (except when pinion teeth butt against flywheel teeth in which case compression of spring between shift collar and overrunning clutch on pinion sleeve will allow switch contacts to close and revolve pinion to meshing position). Return spring on shift lever must have sufficient tension to disengage pinion when pedal released.

Pinion Assembly & Spring (1946 & Later)— Pinion assembly used on these models may be identified by groove in pinion teeth approximately ⅛" from clutch shell. Compression spring must have tension of at least 34 lbs. when compressed to 1". To remove spring, press shift collar down on pinion ring. Spring and collar can be serviced but no attempt should be made to dismantle overrunning clutch mechanism. Clutch is packed with high melting point grease. Do not clean pinion assembly with solvents which may remove grease.

Shift Lever Return Spring—Return spring on shift lever should have tension of 9-12 lbs. (start of travel), 28-35 lbs. (end of travel). Weak spring may cause sluggish disengagement particularly in cold weather or if shaft is gummy.

Switch Test—Switch contacts are defective if voltage drop 0.5 volts or higher when checked with voltmeter at switch terminal with starter cranking engine.

DELC -REMY MANUAL PINI N SHIFT

DELCO-REMY STARTER CONTROLS (ENCLOSED HOUSING)

►1958 *BUICK STARTING MOTOR SOLENOID "S" TERMINAL SEALING (To Prevent Moisture Entrance):* When a starting motor, Part No. 1107667, having a solenoid Part No. 1119919 is disassembled for any reason, the nylon washer and nut on "S" terminal should be replaced by a new sealing nut, Part No. 1940361 Do not rotate terminal stud when removing or installing the nut.

DESCRIPTION: "Enclosed Shift Lever" type combined starter switch and solenoid pinion shift operates in exactly the same manner as previous Delco-Remy "Solenoid Starter Switches (No Relay)". The solenoid has been redesigned for more efficient operation and the entire pinion shift lever mechanism has been enclosed in a housing which is integral with the drive housing and end plate. The starter is of the extruded frame type without any opening at the commutator end so that the entire starter and drive assembly is completely enclosed to protect it from dirt and splash. Drive pinion clearance is not adjustable.

TESTING & CHECKING: Solenoid Windings - With switch disconnected from starter motor, the two following current draw tests may be made.

Pull-In Windings (Both Windings in Parallel) - Remove screw from solenoid motor terminal and bend field leads slightly until clear of terminal. Ground solenoid motor terminal with a heavy jumper wire, then connect a 12 volt battery, a variable resistance, and an ammeter of 100 amperes capacity in series with solenoid "S" terminal. *(NOTE* - The "S" terminal is marked, and is located on engine side of motor field strap connector on front of solenoid). Connect a heavy jumper wire from solenoid base to ground post of battery, then connect a voltmeter between base of solenoid and solenoid "S" terminal. Slowly adjust resistance until voltmeter indicates 10 volts. Reading on ammeter should be as indicated in 'Test Specifications" below.

Hold-In Winding - After completing above test, remove jumper wire from solenoid motor terminal and readjust the variable resistance until voltmeter reads 10 volts. Ammeter reading should be as indicated in "Test Specifications" below.

►*TESTING NOTE:* If solenoid does not test within specifications, replace the solenoid assembly.

Test Specifications

Pull-in Windings - 40-45 amps. (Exc. 1119986); 49-55 amps. (1119986), at 10 volts with relay solenoid at room temperature.

Hold-in Winding - 10-12 amps. (Exc. 1119986); 10.5-12.5 amps. (1119986), at 10 volts with relay solenoid at room temperature.

Pinion Clearance: *(NOTE - Pinion clearance cannot be adjusted. If not correct, motor must be disassembled and defective parts replaced).* To check clearance, connect a 6 volt battery between "S" terminal and ground. *(CAUTION* - Do not connect battery to "R" ignition coil terminal. To prevent motoring, connect a heavy jumper wire from solenoid motor terminal to ground). With the solenoid energized, push pinion away from stop retainer as far as it will go, then use a feeler gauge to check clearance between pinion and retainer. Clearance should be .010-.140"

►*SOLENOID INSTALLATION NOTE:* When installing solenoid, apply sealing compound on both sides of solenoid flange where it extends between drive housing and field frame.

STARTER CONTROL RELAY (BUICK): Check and adjust relay as follows:

Relay Specifications
(Delco-Remy No. 1116921 & 1116963)

Contact Closing Voltage—3.8-5.0 volts. Armature should "seal" to core at not more than 0.2 volts above closing voltage.

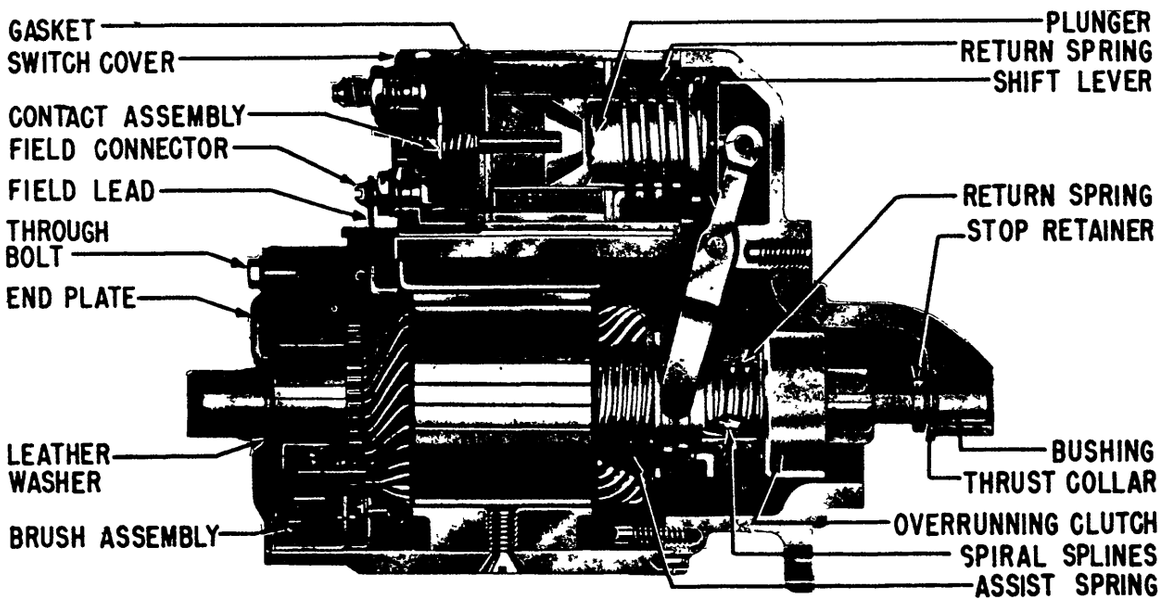
Contact Opening Voltage—Not less than 0.6 volt.

Contact Gap—.025" (.020-.030").

Air Gap—.011" minimum with contacts closed.

CHECKING & ADJUSTMENT

Checking Operation—Use rheostat (must have 10 ohm resistance and 2 ampere capacity) and accurate low reading voltmeter. Connect rheostat to relay terminals #1 and #4 (CAUTION—rheostat must be turned to provide full resistance), connect voltmeter to relay terminals #3 and #4. Make certain that ignition switch turned OFF. Slowly decrease resistance by turning rheostat and note voltmeter reading at instant relay contacts close and solenoid switch operates (can be checked by test lamp connected between relay terminal #2 and ground). Voltage reading at this point should agree with "Contact Closing Voltage" in specifications above. Continue to decrease resistance until slight "click" occurs indicating that armature has sealed to the core. Voltage reading at this point should be not more than 0.1 volt higher (6 Volt Relay), 0.2 volt higher (12 Volt Relay) than contact closing voltage. Quickly cut out all resistance to saturate relay magnet core fully, then quickly increase resistance and note voltage reading at instant relay contacts open (if test lamp used, light will go out at this point). Voltage reading at this point should agree with "Contact Opening Voltage" in specifications above.



Relay Adjustment

Contact Closing Voltage—Bend armature spring post **down** (to increase spring tension and closing voltage) or **up** (to decrease spring tension and closing voltage).

Sealing Voltage & Contact Opening Voltage—Adjust by varying air gap (see below) or by changing the closing voltage (CAUTION—closing voltage must be kept within specifications).

Contact Gap—Adjust by bending upper armature stop.

Air Gap—Adjust by bending lower contact support (check air gap by pressing armature down until contacts just touch, then measure between armature and core with feeler gauge).

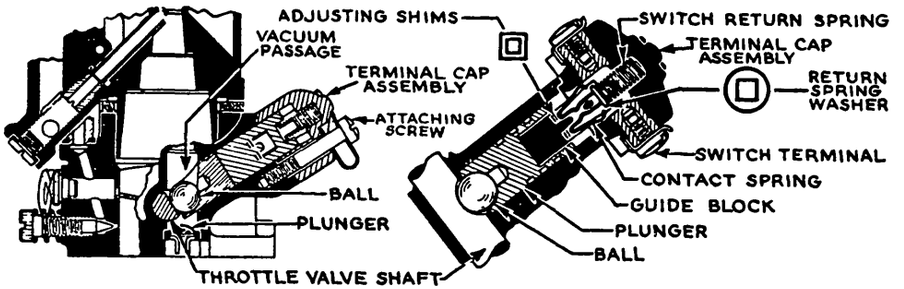
DELCO-REMY "ENCLOSED SHIFT LEVER" SOLENOID PINION SHIFT

CARTER CAR STARTER

►**SERVICE CAUTION:** Car Starter is built in carburetor throttle body casting and must be removed when carburetor is disassembled for servicing (carburetor throttle valve shaft cannot be taken out until switch dismantled and switch ball taken out). CAUTION—Use care not to lose small square switch adjusting shims when switch disassembled

DESCRIPTION & OPERATION: Switch is plunger type mounted on carburetor casting and operated by steel ball which engages switch plunger and flat on carburetor throttle valve shaft when engine is not running. Depressing accelerator pedal to open throttle forces switch plunger up until 'W' shaped contact spring on upper end completes circuit between two brass contact blocks in the switch cap. When the engine begins to fire, switch ball is drawn up out of engagement by manifold vacuum (ball blocks vacuum passage as long as engine is running) so that switch is inoperative. When engine stops, throttle must be closed momentarily to allow switch ball to drop down between throttle shaft and switch plunger.

ADJUSTMENT: Checking Switch Timing - *NOTE - 1957-60 Synchro-mesh models must be checked and adjusted with carburetor off the car. Other models can be checked and adjusted with carburetor installed.*



1957-60 Synchro-mesh Cars - Connect a 12 volt battery and test lamp across switch terminals so lamp will light when switch makes contact. Block choke valve wide open so fast idle cam is in slow idle position, then hold carburetor in normal upright position and insert a ¼" drill between throttle body and lower edge of one primary throttle valve at center. With valve closed against drill, the switch should make contact and light test lamp. Remove ¼" drill and insert a 7/64" drill in same location. With valve closed against drill the switch should be open so test lamp does not light. If switch does not operate properly adjust by changing shims (see below).

1954-60 All Models (Exc. 1957-60 Synchro-mesh) - Measure unloader arm travel (1954 & earlier cars), throttle arm travel (1955 & later cars) as follows: Back off throttle stopscrew, turn fast idle cam to slow idle position, see that throttle valves are fully closed. On 1954 and earlier cars place a 6" scale against choke unloader arm and make a pencil mark on float bowl opposite edge of scale. On 1955 and later cars hold scale against flat face of throttle lever lower arm which contacts the dashpot so that scale rests on rocker arm cover. Make a pencil mark on rocker arm cover at front edge of scale. Turn ignition switch on (or use test lamp and battery connected to switch terminal to check switch closing), open throttle slowly while holding scale in position (as indicated above), until starter pinion just engages flywheel (or test lamp lights) indicating that switch contacts have closed. Make a second mark on float bowl (1954 & earlier), or rocker arm cover (1955 & later), at same edge of scale. Measure distance between these two marks which indicate unloader arm or throttle arm travel. See table below for specifications. To adjust change shims (see below).

Adjustment (Retiming Switch) - Add or remove square brass adjusting shims located on bakelite guide block under "W" shaped contact spring (see Disassembly below). *NOTE - These shims have square hole which engages tongue on guide block. So not confuse these shims with round spring seat washer which seats on middle leg of contact spring.*

Unloader or Throttle Arm Travel (For Switch Timing)

Car Model & Carb.	Unloader or Throttle Arm Travel
1954 Buick (2-Bbl Carb.)	15/16-1 5/16"
1954 Buick (4-Bbl Carb.)	¾-1 1/16"
1955 Buick (2-Bbl Carb.)	29/32-1 7/16"
1955 Buick (4-Bbl Carb.)	9/16 15/16"
1956 Buick (2-Bbl Carter)	¾-1 1/8"
1956 Buick (4-Bbl Carter)	½-13/16"
1956 Buick (4-Bbl Rochester)	¾-1½"
1957 Buick (2 Bbl Carter)	5/8-15/16"
1957 Buick (4-Bbl Carter)	3/8-11/16"
1957 Buick (2-Bbl Stromberg)	13/16 1 3/16"
1957 Buick (4-Bbl Rochester)	½-¾"
1958 Buick (2-Bbl Carter)	1 1/16-1 5/8"
1958 Buick (4-Bbl Carter)	13/16-1 5/16"
1958 Buick (2 Bbl Stromberg)	1-1 7/16"
1958 Buick (4-Bbl Rochester)	13/16-1 3/8"
1959-60 Buick (2-Bbl Carter)	9/16-7/8"
1959-60 Buick (2-Bbl. Stromberg)	3/4-1 1/8"
1959-60 Buick (4-Bbl Carter)	1/2-3/4"
1959-60 Buick (4-Bbl Rochester)	1/2-13/16"

CARTER CAR STARTER

REMOVAL & DISASSEMBLY: Disconnect and tape the leads on switch terminals (wire with red tracer on terminal nearest engine is 'hot' with ignition turned on). Remove switch terminal cap attaching screw, hold-down clip, switch cap, withdraw return spring, guide block and contact spring assembly, switch plunger and ball. Be careful not to lose spring seat washer (on contact spring) or adjusting shims (on guide block under contact spring).

Servicing. Clean switch ball, plunger, cylinder, carburetor vacuum chamber and inlet screen, throttle valve shaft flat with gasoline. Check 'W' contact spring and switch return spring. Replace these parts if dimensions incorrect. **'W' Contact Spring**—Distance across spring at widest part (across outer contact legs) should be 7/16" (plus 1/32", minus 0") with spring seat washer seated on middle leg of spring.

Return Spring—Free length of spring should be 11/16-¾" and pressure of 32 ozs should be required to compress spring to length of 3/8".

REASSEMBLY: When installing switch plunger make certain that lip on inner end of plunger is down toward manifold (lip will prevent ball engaging on flat of shaft if installed incorrectly). See that adjusting shims are in place under contact spring, and spring seat washer seated on middle leg of contact spring. Coat contact surfaces of terminal cap lightly with Beacon M-285 lubricant or Rocker Arm Grease No. 1 (petroleum jelly can be used if other lubricants not available). *CAUTION*—Do not use other lubricants and do not lubricate switch ball or plunger. Make certain that return spring enters socket in switch cap and that cap is properly seated in counterbore in casting.

►CHANGES, CAUTIONS, CORRECTIONS

►*1953 LINCOLN & MERCURY BRAKE PEDAL TRAVEL CAUTION:* A minimum of 1" (Lincoln), 1½" (Mercury) pedal to floor clearance must be maintained (engine running).

►*1953 EXHAUSTION OF VACUUM SUPPLY CAUTION (Engin Stall d)·* It is possible to exhaust vacuum supply with two applications of brake (engine stalled) *(NOTE–See Oldsmobil Production Change below).* With no vacuum assist pedal pressure required to stop vehicle is greatly increased. If engine stalls (or is parked) on steep grades, stop car completely, set hand brake firmly, turn off ignition, and place selector lever in "R" position. Before releasing hand brake be sure engine is running.

►*1953 OLDSMOBILE SCLENOID VALVE ADDITION & VACUUM RESERVE TANK PRODUCTION CHANGE* A solenoid valve, mounted on top of an enlarged vacuum reserve tank, has been added to Power Brake Unit of late 1953 cars. Solenoid is connected into stoplight switch energized power assist to brakes is available and will permit 3 or 4 brake applications with engine off or stalled at coasting speeds below 20 MPH. **Oldsmobil S l n id Valve Checking and Adjustment–** With transmission in neutral and engine stopped, coast 20-30 MPH and apply brakes. Brake operation should be smooth and the same as with engine running. If there is any catch or hard spot in pedal travel, the stop light switch should be adjusted as follows Loosen stop light switch attaching screws, then adjust switch so that stop lights make contact with first 1/8"-1/4" of pedal travel. Tighten attaching screws, again check to be certain that stop lights go off when brake pedal is in fully released position. Re-check operation by coasting and applying brakes.

►*1953-54 LINCOLN & MERCURY BRAKE MASTER CYLINDER OPERATING LEVER BRACKET INSTALLATION CAUTION.* When installing Lever Bracket, Part No LA-22519-A., into pedal support brace, it is necessary to install lower retaining bolts with head of bolt to inside of pedal support, with nut and lockwasher installed on outside. If installation made with nut to **insid** of pedal support, full travel of brake pedal will be restricted.

►*1955 CHEVROLET BRAKE BLEEDING CAUTION (To Prev nt Trapping Air in System)* Since no bleeder is provided at forward end of power unit to permit trapped air to escape from forward end of unit (due to slight tilting above horizontal line from pushrod eye for design reasons) one of two following methods can be used to eliminate any air trapped in system

Unit Off Car: Fill master cylinder approximately half full, with forward end of unit tilted down below a horizontal line from pushrod eye, before unit is installed in position on dash panel

Unit On Car: Raise rear end of car until forward end of power unit is tilted below a horizontal line from pushrod eye

►*1955 CHEVROLET SLOW BRAKE PEDAL RETURN CORRECTION* Check to see that pushrod has been installed to **inboard** side of lever assembly at the pedal linkage instead of to outboard side, check rubber boot to see that bellows have been pulled through smaller hole in dash panel and mounting plate (This should be done at same time power unit is being assembled to mounting plate) and that bellows are not all gathered on front side of dash panel and mounting plate, causing bind on pushrod, check lubrication at pedal linkage Lubriplate where necessary On early cars, after checking as indicated above and brake pedal return is still slow, remove power unit from front of dash Remove rubber boot, and squirt some rubber lubricant between valve sleeve into which pushrod is assembled and sleeve bore in valve assembly (This will lubricate "O" ring seal in valve sleeve)

►*1955 CHEVROLET VACUUM LEAK CAUTION (Windshield Washer Installation):* Some V-8 engine cars equipped with power brakes and electric windshield wipers (early cars) did not have proper Tee connection at carburetor for washer installation When washer being installed be sure proper fitting is in carburetor If not, install Tee Part No 3718911 to make washer connection **Under no circumstances cut into power brake line at any point.**

►*1956 CADILLAC BRAKE PEDAL LINKAGE BIND CAUSING BRAKE DRAG·* Binding can exist at brake rod-to-relay connection, pedal rod at toe-board hole, and pedal rod to felt air seal retainer *NOTE* - Check level of pedal for correct horizontal position in car as viewed from seat before making repairs to eliminate binding. Correct by shimming between attaching bracket and steering column.

DESCRIPTION: Self-contained hydraulic vacuum power braking device utilizing engine intake manifold vacuum and atmospheric pressure for its power It consists of three separate units as follows

Power Unit: Three elements are combined to make up this single unit, namely

(1) Vacuum Power Cylinder comprising a cylinder power piston, and piston return spring

(2) Hydraulic Master Cylinder containing an hydraulic plunger, compensating valve residual check valve, and fluid reservoir

(3) Control Valve, mechanically actuated, which controls degree of brake application or release in accordance with foot pressure applied to pedal

Vacuum Res rv Tank provides vacuum assist for a limited time when engine stalls

Manif ld Ch ck Valve, in vacuum source line, maintains vacuum in unit should engine stall

OPERATION· With engine running, brakes unapplied, both sides of power piston are open to atmospheric pressure Application of the brake pedal causes vacuum port to open, thus connecting the forward side of vacuum power piston and rear side of reaction diaphragm to engine vacuum This pressure differential causes power piston to move forward, thereby exerting a thrust on the hydraulic plunger This increases line pressure to the four wheels Release of the brake pedal restores the pressure balance in the power cylinder

CHECKING & ADJUSTMENT: Check all parts of the power brake system before disassembling the Power Brake Unit whenever brake trouble experienced

Adjustments: None required If unit becomes faulty, manufacturer recommends that unit be overhauled using Power Brake Repair Kit *NOTE*–Use all parts in kit *DISCARD ALL OLD RUBBER PARTS*

Bleeding Brakes· Bleed in same manner as standard brake system Do not use vacuum assist while bleeding Engine should not be running and vacuum reserve should be reduced to zero by applying the brake several times before starting bleeding

Air Cleaner· Clean twice a year To clean, remove air cleaner and thoroughly wash in cleaning solvent Allow cleaner to dry before reinstalling

Refilling Fluid Reservoir· Check level every 1000 miles If level not up to "L" mark on dipstick (Oldsmobile), ¼' from filler plug opening (Lincoln & Mercury), within ½ from filler plug opening (Others), add brake fluid

Vacuum & Hydraulic Line Inspection: Every 5000 miles, check hose tubing and connections Replace deteriorated hose or damaged tubing

TESTING· Road test brakes by making a brake application at about 20 MPH to determine if vehicle stops evenly and quickly If pedal has a spongy feel when applying brakes, air may be present in hydraulic system. Bleed system as described above When engine is stopped and transmission is in neutral, apply brakes several times to remove all vacuum in system Depress brake pedal, hold light foot pressure on pedal and start engine If vacuum system is operating, pedal will tend to fall away under foot pressure, and less pressure will be required to hold pedal in applied position If no action is felt, vacuum system is not functioning Stop engine and again remove all vacuum in system Depress brake pedal and hold foot pressure on pedal. If pedal gradually falls away under foot pressure, hydraulic system is leaking If brake pedal travels to within 1" of toeboard, brake shoes require adjustment or relining

LUBRICATION: Piston packing seal is lubricated at time of assembly and requires no further lubrication *CAUTION–NEVER lubricate vacuum valve.*

TROUBLE SHOOTING· The following conditions apply to Power Brake operation Be sure brake shoes, drums, linkage, and adjustments correct before repair of Power Brake System

Hard Pedal· Vacuum failure due to faulty vacuum check valve, collapsed vacuum hose, plugged vacuum hose or fittings, leaking vacuum reservoir or vacuum hose and pipe connections, bound up pedal mechanism, glazed

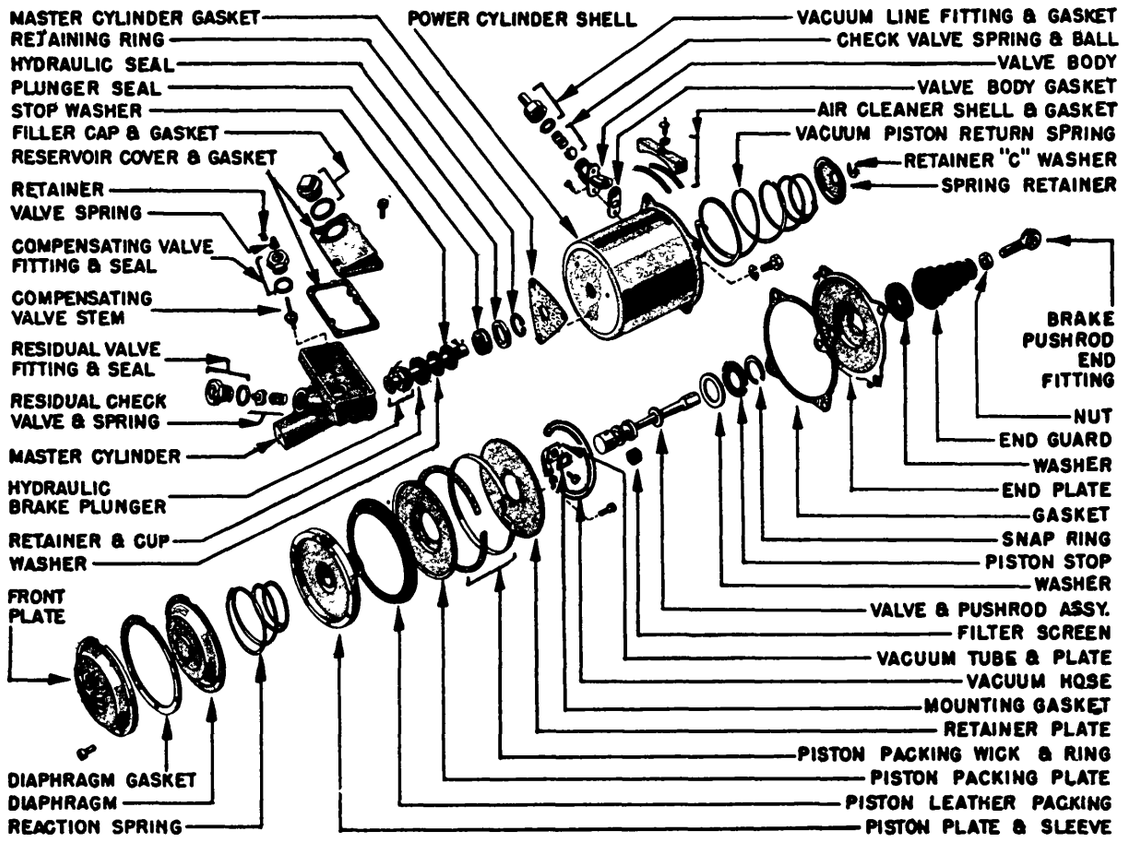
CONTINUED ON NEXT PAGE

BENDIX POWER BRAKE UNIT "VACUUM REACTION" TYPE (Continued)

linings; grease, brake fluid, or water on linings; vacuum leak in unit between piston plates, past leather piston packing, between vacuum cylinder and master cylinder, or around hydraulic plunger seal; restricted air cleaner; jammed pushrod and valve plunger; broken counter-reaction spring; leak past atmospheric poppet; vacuum hose on piston loose or restricted.

"Grabby" or Severe Brakes: Grease or brake fluid on linings; scored drums; anchor pins loose; vacuum leak in the reaction diaphragm; sticking pushrod and valve plunger; faulty pivot arm and vacuum poppet action; restricted diaphragm passage.

P dal Goes To Floor (Or Almost To Floor): Brakes require adjustment; air in hydraulic system; hydraulic leak in lines or at wheel cylinders; fluid reservoir needs replenishing; cracked drums or broken linings; hydraulic leakage at compensating valve, hydraulic plunger seal, compensating seal or outlet fitting seals.



Brakes Fail To Release (Or Slow Release): Anchor pins loose; bound up brake pedal linkage; brakes improperly adjusted; faulty residual check valve; excessive hydraulic plunger seal friction; faulty compensating valve; excessive piston packing friction; restricted air passage in piston plate; restricted air cleaner; sticky pushrod and valve plunger; broken return spring.

REMOVAL (CADILLAC): Disconnect relay to unit rod at clevis. Disconnect relay rod from pushrod. Disconnect both vacuum hoses from power unit. Disconnect hydraulic line at outlet fitting. Remove four screws, lockwashers and nuts from cylinder mounting bracket and remove power brake assembly from car.

REMOVAL (CHEVROLET): From engine side of dash panel remove vacuum lines from vacuum inlet tube on intake manifold (top of engine on V8, left side center on 6 Cyl.). Remove vacuum line to vacuum reservoir. Remove stop light wire connection. Remove hydraulic line from hydraulic cylinder. From inside body remove lever to pushrod retaining bolt washer, lockwasher and nut and disengage pushrod from pushrod lever. Remove bolts and lockwashers retaining power brake unit to dash unit and remove unit from vehicle.

REMOVAL (LINCOLN & MERCURY): Disconnect pushrod from brake pedal. Remove master cylinder outlet fitting bolt (NOTE–It is not necessary to remove stop light switch wire or hose assembly from outlet fitting). Do not disturb outlet fitting in master cylinder. Loosen manifold hose clamp at check valve, remove hose from valve. Loosen vacuum reserve tank hose clamp at check valve and remove hose from valve. Remove bolts securing power brake assembly to bracket on dash panel, remove assembly.

REMOVAL (OLDSMOBILE): Disconnect hydraulic line at power brake master cylinder. Use care to prevent dirt entering hydraulic line and secure hose so that open end is above level of junction assembly to prevent loss of fluid. Plug master cylinder outlet with rubber stopper. Disconnect leads from stoplight switch and fold back floor mat. Remove three brake pedal bracket attaching bolts. Remove bracket and pedal assembly. Remove mast jacket grommet retainer clip and slide

1954 BENDIX BRAKE POWER UNIT (VACUUM REACTION CONTROL)

grommet up mast jacket. Remove mast jacket cover plate attaching screws. Loosen speedometer cable hold down clip and slip cable from under clip, then remove speedometer cable and grommet from mast jacket cover plate. Remove two cover plate to power cylinder bolts, and remove cover plate while positioning power brake unit so it rests on edge of opening in toe pan. Disconnect vacuum hoses and remove power brake unit through toe pan opening.

►*INSTALLATION NOTE:* When reinstalling hoses, position clamps so screw heads may be reached from below car. Place 5/16" bead of 3M Sealer around entire toe pan groove.

REMOVAL (PACKARD): Disconnect vacuum, atmospheric, and hydraulic lines and stoplight wires from power unit (raise hydraulic line above level of junction assembly to prevent fluid leakage). Disconnect and remove brake and accelerator pedals. Remove steering column grommet retainers, slide grommet up out of way. Remove carpet retainers and fold back carpet. Remove cover plate screws, then remove power brake and cover as an assembly, take out mounting screws and remove power brake from cover.

REMOVAL (PONTIAC): Disconnect vacuum hose from vacuum pipe leading to vacuum tee connector. Raise car and remove engine side apron from left side. Remove electrical cables from behind cable guide on reservoir cover of brake unit. Remove coiled hydraulic pipe from outlet fitting on hydraulic cylinder and from tee connector. Disconnect pushrod from pedal and wires from stoplight switch. Remove nuts from U-bolt retaining pedal pivot bracket to steering column; remove pedal and pivot bracket (with stoplight switch assembly attached). Remove accelerator pedal. Push rubber grommet up on steering column and move floor mat out of way. On Synchro-mesh cars, remove clutch pedal seal retainer and steering column seal retainer and remove seals. On Hydra-Matic equipped cars, remove screws retaining mounting plate to floor pan and remove mounting plate with power brake unit attached. On Synchro-mesh cars, remove screws retaining power brake unit to mounting plate (brake will rest on frame). Remove screws retaining mounting plate to floor pan and remove mounting plate, "jockeying" as necessary to clear clutch pedal. Remove power brake unit. *(CAUTION*–Do not support or carry brake unit by pushrod since pushrod may be pulled out of plunger). Remove

CONTINUED ON NEXT PAGE

BENDIX POWER BRAKE UNIT "VACUUM REACTION" TYPE (C ntinued)

mounting plate from brake unit, if not previously removed, and hose from vacuum cylinder inlet tube.

DISASSEMBLY: *CAUTION–Use extreme care to prev nt hydraulic syst m parts coming in contact with mineral oil or gr as .* Clean all dirt from outside of unit, using care not to allow dirt or solvent to enter unit. Remove fluid filler cap or dipstick and gasket then empty fluid out of reservoir. On Lincoln, remove screw that secures heat shield to booster body, remove shield by sliding it off hydraulic cylinder.

►*CAUTION: B for furth r disassembly, scratch alignment marks at th following points: (1) Vacuum cylind r sh ll and vacuum cylinder end plate. (2) Vacuum cylind r sh ll and hydraulic cylinder casting. (3) Reserv ir cov r and hydraulic cylinder casting. (4) Tube fitting and hydraulic cylind r casting.*

ALL MODELS

Hydraulic Unit: Place hydraulic unit in vise (lead jaws) at its normal mounting angle and remove the six cover screws, cover and gasket. Using a 1 1/8" (thin-wall) socket wrench, unscrew and remove compensator port and valve assembly. Remove rubber seal ring from port fitting. Unscrew hydraulic output fitting and remove fitting and take off rubber seal ring. Remove check valve assembly and valve spring. Separate check valve rubber cup and cup retainer. Remove unit from vise and empty remaining fluid. *NOTE*–Master cylinder piston assembly will be removed after vacuum cylinder is removed from hydraulic cylinder casting.

1954 MODELS

Vacuum Unit: Replace unit in vise. Release lip of valve rod boot from cylinder end plate and slip boot off over end of rod. Remove screws holding cylinder end plate and gasket and remove these parts. With a small-nose pliers compress ends of valve stop washer snap ring and pry out opposite side of snap ring. Remove snap ring, valve rod and valve assembly. Remove the screen from around vacuum valve. *(CAUTION*–Protect polished surface of vacuum valve assembly). Remove hose from vacuum inlet tube. Compress the vacuum piston into cylinder about ½" and remove inlet tube assembly and gasket. Lift out the piston assembly. Using care not to compress the master cylinder piston from its released position, compress the piston return spring about ½" and remove the return spring seat retainer, spring seat and return spring. Remove the three vacuum cylinder, mounting bolts and lockwashers. Remove vacuum cylinder, gasket, rubber seal ring and metal encased leather seal from hydraulic cylinder casting. Using special pliers, next remove master cylinder piston cup washer retainer ring and lift the master cylinder piston and seal parts as a unit from the hydraulic cylinder. *(CAUTION*–Protect polished surfaces of master cylinder piston). Remove the steel backup washer, phenolic guide washer, cylinder piston seal and seal retainer from the master cylinder piston.

Vacuum Pist n: Scratch alignment marks on front and rear piston plates. Remove the piston steel and rubber stop washers. Remove the five packing plate screws, retainer plate, wick expander spring, wicking, vacuum piston seal retainer and seal. Turn unit over and remove the five piston plate screws and separate the front and rear piston plates, diaphragm assembly, counter reaction-spring, gasket and vacuum valve return spring.

1955-58 MODELS

Vacuum Unit: 1) Replace unit in vise. Release lip of valve rod boot from cylinder end plate and slip boot and felt off over end of rod. Bend up two tabs on end plate and separate end plate and end plate gasket from cylinder. Slide vacuum hose off vacuum tube attached to vacuum cylinder. Remove air cleaner screw and separate screw gasket, shell, hair and rubber seals from vacuum cylinder. Remove two vacuum tube attaching screws, vacuum tube and gasket. *(CAUTION*–Inspect inner surface of vacuum cylinder under holes for burring from attaching screws. Remove burrs to prevent damage to power piston assembly). Pull out piston assembly from vacuum cylinder.

2) Compress piston return spring about ½" and remove the return spring seat retainer, spring seat and return spring. Remove the three vacuum cylinder mounting bolts and lockwashers. Remove vacuum cylinder, gasket rubber seal ring and metal encased leather seal from hydraulic cylinder casting. Using special pliers, next remove master cylinder piston cup washer retainer ring and lift the master cylinder piston and seal parts as a unit from the hydraulic cylinder. *(CAUTION*–Protect polished surfaces of master cylinder piston). Remove the steel backup washer, phenolic guide washer, cylinder piston seal and seal retainer from the master cylinder piston.

Vacuum Piston Stop, Compensating Stem & Vacuum Hose: Remove vacuum hose from piston tube. Remove tube screw and separate tube and rubber seal from piston assembly. Visually inspect condition of rubber stop. If there is no evidence of wear or damage, remove screws and remove steel stop washer with rubber stop attached. If rubber stop warrants replacing, separate stop from steel washer before removing steel washer. Remove compensating stem diaphragm and compensating stem.

Vacuum Piston, Valve Pushrod & Plunger: Hold rear piston plate assembly in vise using care not to damage surface at vacuum tube port. Loosen five piston plate screws and separate front piston plate, gasket, diaphragm assembly and counter-reaction spring from rear piston plate assembly. Remove vacuum poppet spring screw, spring from rear piston plate. Using pliers, remove atmosphere poppet retaining clip. Break clip, if necessary, to remove from poppet stem. Separate atmosphere poppet spring and atmosphere poppet from piston plate. Remove pushrod and plunger, and vacuum poppet assembly from piston plate. From groove in bore of piston plate, remove plunger stop ring. Using sharp tool under end of Spirolox ring, remove ring from groove at end of plunger. Separate pivot washer and pivot arm from plunger. Remove clip and separate vacuum poppet from pivot arm. From recess around plunger remove flat rubber seal.

R ar Pist n Plat Packing & Plat s–Place rear piston plate on bench, with packing and plates facing upward. Remove six retainer plate attaching screws, retainer plate, ring wicking, piston packing plate and leather piston packing.

CLEANING & INSPECTION: Thoroughly wash all parts in diacetone alcohol. Use air hose to blow dirt and cleaning fluid out of recesses and internal passages. Remove rust or corrosion from bore of vacuum cylinder shell with fine emery cloth. Place all cleaned parts on clean paper or cloth to prevent possibility of dirt being assembled into power brake. Inspect all parts for wear or damage and replace as necessary. Particular attention should be given to following items:

Vacuum Cylinder Shell: Inspect shell for scores, pits, dents or nicks, or damaged threads in nuts or in mounting flanges.

Hydraulic Cylinder Casting: Examine bore down one inch from open end. For the hydraulic cup to seal properly, this portion of bore must be free from scores, deep scratches or corrosion. The sealing surfaces at the reservoir cover, compensating port, and hydraulic outlet port must be free of scoring, pitting, dents and nicked edges. Also check casting for cracks and damaged threads.

Hydraulic Port Fitting: The surface at the small end of the fitting must be free from scoring or corrosion which might prevent sealing with rubber cup of residual check valve.

Compensating Port Fitting: Inspect surface around port opening, inside threaded end of fitting, for scoring or corrosion which might prevent proper seating of compensating valve.

Valve Supply Tube: Make sure tube braze is secure and that tube plate is not distorted.

Piston Plates: Examine plates for cracks and damaged threads. Inspect plunger bore in rear piston plate and poppet seats for scratches and nicks. **Do not** attempt to refinish bore. Replace with new plate, if necessary.

Hydraulic Plunger & Washer Assembly: Inspect polished surface for scores, pits, or dents. **Do not** attempt to refinish plunger surface. Replace with new assembly.

Pushrod & Plunger Assembly: Rod must pivot freely in plunger without any noticeable end play. Inspect plunger for scores, pits, or dents on outside diameter of polished surfaces. **Do not** attempt to refinish plunger surface. Replace with new assembly, if necessary.

REASSEMBLY: Before reassembly, make sure working area, parts, and tools are free of dirt, grease and oil.

1954 MODELS

Master Cylinder Piston: Dip piston and cup in hydraulic brake fluid. Install cup retainer on piston with small end of retainer toward washer on end of piston. Dip cup in brake fluid, then install lip side of cup on cup retainer. Place piston-retainer-cup sub-assembly in hydraulic cylinder. Take care not to damage lip of cup as it enters cylinder bore. Install the phenolic guide washer and piston cup steel stop washer in place and install the retaining ring. Hold master cylinder piston in its outward position and install leather seal (with lip toward hydraulic cylinder).

Vacuum Piston: Place rear piston plate on bench with rear side facing up. Install Vacuum Piston Packing Assembly Ring over the piston plate, then install leather piston packing seal, lip side up, until it seats in recess of piston plate. Install vacuum piston packing

CONTINUED ON NEXT PAGE

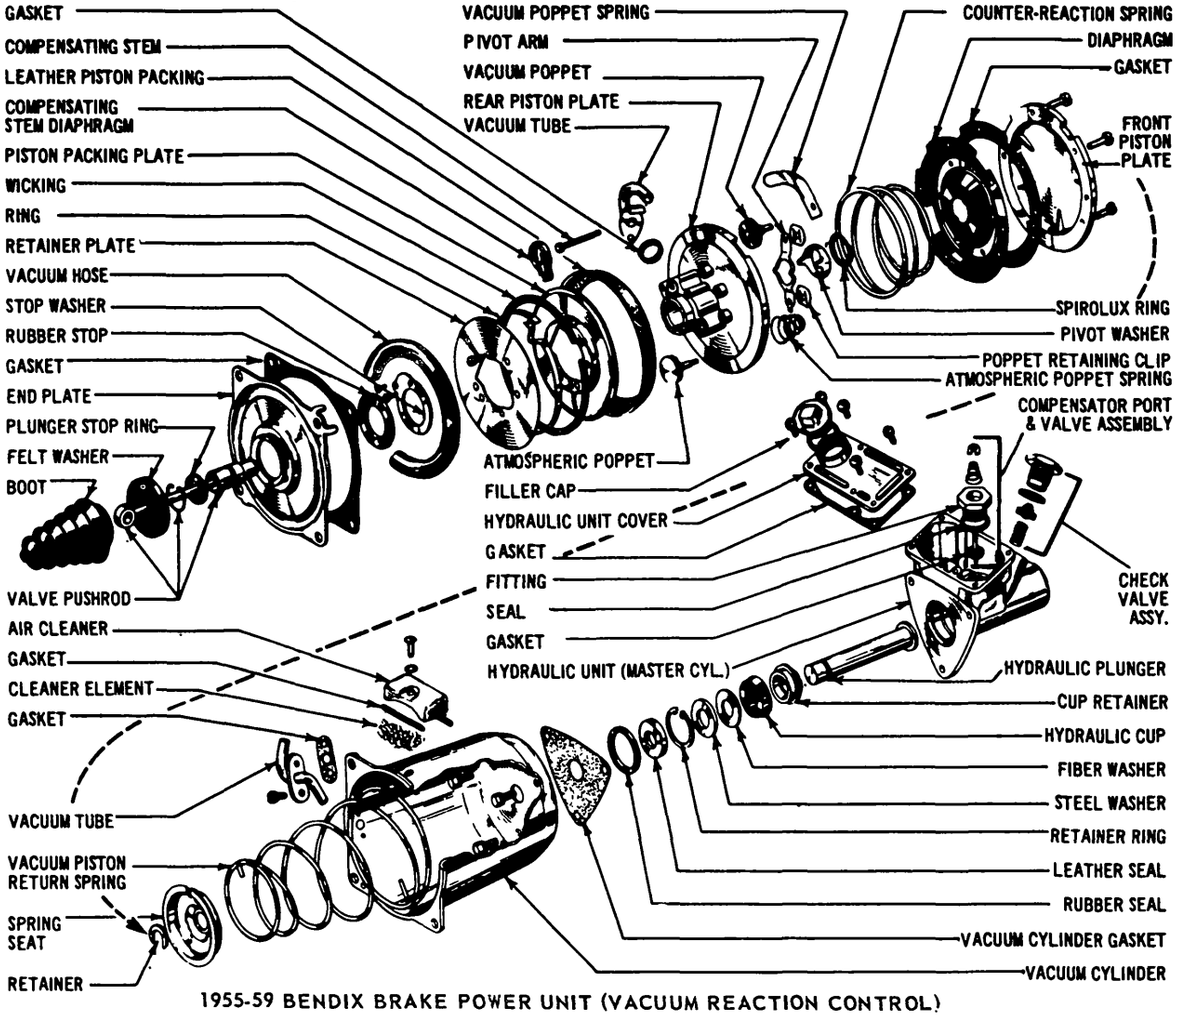
BENDIX POWER BRAKE UNIT "VACUUM REACTION" TYPE (Continued)

seal retainer, wicking, wick retaining expander spring, wick retaining plate, and install the five retaining screws *(CAUTION–Care must be taken when installing these screws to apply sufficient downward pressure on screwdriver to partially compress the packing seal and thoroughly engage screw threads to prevent stripping the threads).* Turn vacuum piston over and install Diaphragm Installation Guide Pins into screw holes, then place the counter-reaction spring, small end down, on piston plate, and install reaction diaphragm (with large diaphragm plate toward rear piston plate) and gasket, over pins. Align the two air passage cutouts. Install the valve return spring with small end into reaction diaphragm (this will be over the back of rubber pad). Install front piston plate, aligning the air passage cutouts or alignment marks. Press down front plate, compressing the spring, and remove one guide pin at a time, replacing each with a screw. Tighten screws uniformly. Saturate new wicking and wipe leather seal with a maximum of two teaspoons full of **shock absorber oil**. Fasten the vacuum tube and hose assembly and gasket to rear piston plate with two screws.

Vacuum Cylinder: Install master cylinder rubber seal ring and the cylinder gasket. Match aligning marks on vacuum cylinder and on hydraulic cylinder casting and install mounting bolts and lockwashers. Tighten to 4-5 ft. lbs. torque. Install the piston return spring engaging the hooked end of the large end of the spring between a mounting bolt and a small hump in the cylinder (any of the three). Place the spring retainer over the piston engaging hooked end of small end of spring in slot of retainer. Install retainer washer. Apply a thin coating of shock absorber oil to inside walls of vacuum cylinder and insert vacuum piston assembly into cylinder and align open end of hose with the center of the large elongated hole in vacuum cylinder. Push piston assembly into cylinder making sure that bore in vacuum piston front plate fits over master cylinder piston. Rotate piston assembly clockwise 20° to 30" and then 20° to 30° counter-clockwise. Move the piston through its full stroke a number of times to make certain open end of vacuum hose will be centered under elongated hole in vacuum cylinder after piston finds its normal working position. Install tube assembly, gasket and screw on vacuum cylinder. Tighten screw firmly and slip the hose on its connection. Again push piston into cylinder to its full stroke a number of times permitting it to return by itself and note if return spring causes piston to rotate. If it rotates enough to cause the coiled hose to rub against the inlet connection, remove piston and move piston return spring 120°.

Hydraulic Cylinder: Dip compensator rubber seal ring in brake fluid and install on compensator port fitting. While holding piston assembly forward in cylinder about ½", install port fitting and valve assembly and tighten securely. Dip line check valve rubber cup in brake fluid and assemble on cup retainer. Position spring and cup-retainer assembly on hydraulic output fitting lower face at small end of fitting. Invert the power unit and screw fitting into place, using care to see that parts remain in correct alignment. Tighten to 30-42 ft. lbs. torque. Assemble copper gasket, hydraulic tube fitting and the second copper gasket over fitting bolt. Screw assembly into outlet, aligning the marks previously made.

1955-58 MODELS



Compensating Valve: Insert stem of valve poppet assembly through hole in threaded end of fitting. Assemble large coil of poppet spring to fitting over end of poppet. Hold poppet on seat, compress spring, and insert "C" washer retainer in groove at end of stem. Crimp ends of "C" washer together to retain in place. Coat rubber seal with brake fluid and assemble over threads of fitting.

Master Cylinder: 1) Coat residual check valve rubber seal with brake fluid and place over threads of hydraulic outlet fitting in inverted position, and insert cone end of cup and retainer assembly in end of fitting. Center check valve spring in recess of rubber cup. Hold master cylinder casting upside down and thread outlet fitting into cylinder. Tighten to 50 ft. lbs.

2) Insert washer end of plunger into cylinder. Place cup retainer on plunger so that smaller inside diameter of retainer is toward plunger washer. Coat hydraulic cup with brake fluid and place over plunger; lip on cup must be toward cup retainer. Place Spauldite guide washer against cup. Place steel washer against guide washer. Slide all parts into bore of cylinder. *CAUTION*–Use care so as not to cut cup when placing on plunger and when inserting cup into bore of cylinder. It will be necessary to use a small screwdriver or similar tool having a smooth edge to start lip into bore.

3) Press parts into cylinder bore and insert snap ring using snap ring pliers. Be sure snap ring is engaged

1955-59 BENDIX BRAKE POWER UNIT (VACUUM REACTION CONTROL)

BENDIX POWER BRAKE UNIT "VACUUM REACTION" TYPE (C ntinued)

in recess. Push in on hydraulic plunger and then install compensating valve assembly into master cylinder. Pull back on plunger **to be sure** plunger washer tilts compensator valve. Tighten fitting to 15 ft. lbs. Place cover gasket on reservoir of cylinder. Align cover scribe marks and replace cover screws, with exception of rearmost screw on right hand side. Re-place filler cap or dipstick gasket, replace filler cap.

R ar Pist n Plat Packing & Plates: Place piston assembly flat on work bench inside of piston assembly ring. Place leather packing against piston with lip up. Place packing plate inside leather packing, with beveled edge of plate down against packing, so that "cutouts" and holes in plate are aligned with piston. Coil wicking inside lip of leather packing Cut wicking to required size Remove wicking and dip in vacuum cylinder oil, let excess drip off and reinstall wicking. Coil expander ring inside wicking with barbs pointing upward into wicking. Engage notch at loop end of ring with hook at opposite end Replace and align wicking retainer plate Replace screws and tighten evenly

Vacuum Pist n, Valv Pushrod & Plunger: 1) Place stem of vacuum poppet in hole at rounded end of pivot arm and install two retaining clips making sure that clips are pushed down against pivot arm A piece of bar stock with 1/8' hole in end, or piece of brake pipe with flared end, facilitates installation Place rubber seal in recess of pushrod plunger with lip of seal toward pushrod Coat plunger with Lubriplate, place into bore of rear piston plate and engage snap ring in recess in bore of piston plate Place pivot arm vacuum poppet sub-assembly over end of plunger, insert pivot washer and engage Spiroluv ring into groove at end of plunger (Engage end of ring in groove and then screw into place) Place vacuum poppet spring into recess of piston plate and with end of spring over end of vacuum poppet stem, insert screw Place atmospheric poppet spring between pivot arm and piston plate with large coil of spring towards atmospheric port From opposite side of piston plate, place atmospheric poppet so that stem passes through plate, spring, and hole in pivot arm Install retainer clips on stem of poppet in same manner as before A length of round rod with a flat end can be used to back up atmosphere poppet when installing clips

2) Clamp rear piston plate assembly in vise and screw guide pins into place Place large end of counter-reaction spring in piston plate Place diaphragm over guide pins so that by-pass holes and notches in diaphragm and plate are aligned. *NOTE*–When by-pass holes and notches are aligned, correct side of diaphragm will be toward piston plate

3) Move diaphragm downward until it seats on spring When properly seated, flange of metal ring will be within counter-reaction spring Place gasket and front piston plate over guide pins, making sure by-pass holes and notches are properly aligned

4) Apply force on front piston plate to compress counter-reaction spring until front piston plate rests on rear piston plate. Loosely install two screws. Remove guide pins, one at a time, and install remaining three screws, Tighten all screws evenly.

Vacuum Piston Stop, Compensating Stem & Vacuum Hose: Place vacuum poppet compensating stem into hole in recess in hub of piston plate. Place compensating stem diaphragm in recess with "by-pass" slot of diaphragm outward and tab to left (when slot is toward you). Place steel stop washer over pushrod, align washer with hub of piston, replace two screws and tighten securely. Soften coating of rubber stop (if stop was removed) with gasoline and cement to steel washer. Position rubber seal in recess of piston, hook plate of tube to piston plate and replace screw, tighten screw securely. Attach vacuum hose to tube and coil hose around hub of piston

Vacuum Cylinder: 1) Pull out hydraulic plunger, place Plunger Seal Installer (J-5405) over end of plunger, and assemble leather seal over seal tool with lip of seal toward master cylinder. Press seal into recess of master cylinder and then remove tool from plunger. Place rubber seal into master cylinder recess around leather seal. Align vacuum cylinder to master cylinder, and with gasket in place, insert three capscrews (and lockwashers), tighten to 6 ft. lbs.

2) Place larger end of vacuum piston return spring in vacuum cylinder making certain hook on spring is between a screw head and a raised projection on end of cylinder. Assemble retainer plate over end of spring, aligning notch with hook on spring. Compress spring, and with retainer plate over end of plunger, insert "C" washer into groove of plunger.

3) Apply thin film of vacuum cylinder oil to bore of vacuum cylinder and to lip of leather packing, insert piston into cylinder so that free end of vacuum hose is in line with center of hole. Push piston into cylinder, adjusting position slightly until hook seats between two web sections of front piston plate. Move piston 20-25° in both directions in cylinder and stroke piston against spring several times by hand, to allow piston to find its normal operating position. Check location of end of hose with respect to center of hole in cylinder. Install tube and gasket and replace two screws. Slide end of hose onto vacuum tube approximately 5/8". Operate piston by hand through its full stroke several times to make certain that hose does not rub against cylinder or piston. Should interference occur, remove and rotate piston to a new web position where interference does not occur.

Air Cleaner & End Plate: Place two rubber seals on bottom edges of air cleaner shell. Place hair in shell. Replace screw and gasket and attach air cleaner shell to vacuum cylinder. Be sure hair is under shell, a small steel scale or similar tool can be used to push hair under ends of shell. Align end plate gasket and end plate and place against vacuum cylinder. Bend over two tabs of end plate to secure plate to cylinder. Install rod guard felt in large end of boot. Dip small end of boot in brake fluid and place boot and felt over pushrod. Attach lip of boot to scallops at center of end plate.

INSTALLATION: To install power brake assembly reverse removal procedure and note the following:

1954 MODELS

Vacuum Valve & Piston: *CAUTION–Check to see that movement of the vacuum piston is within 3/32" t 7/32" from its full released position. This movement should allow compensator valve to close. If this dimension does not check, unit is not assembled properly and should be rechecked.* If dimension checks install vacuum valve screen over the grooved port in vacuum valve and carefully insert the valve and rod assembly into vacuum piston (phenolic guide washer must be in place on rod) and install retainer snap ring. Install felt washer and rubber boot. Match fluid reservoir cover alignment marks and install cover and gasket, and filler cap and gasket.

1955 MODELS

Hudson & Nash: To prevent any contact during operation, a minimum of ¾" clearance must be maintained between centerline of pushrod-to-bell crank clevis pin and outer surface of front adjusting link locknut.

Pontiac: There should be approximately 1/8" clearance between pushrod and bore of plunger at top or 12 o'clock position with brake pedal released. If improper clearance noted, loosen brake pedal pivot bracket and shift slightly to obtain clearance. *NOTE*– If clearance cannot be obtained, check for bent pushrod or bent mounting plate.

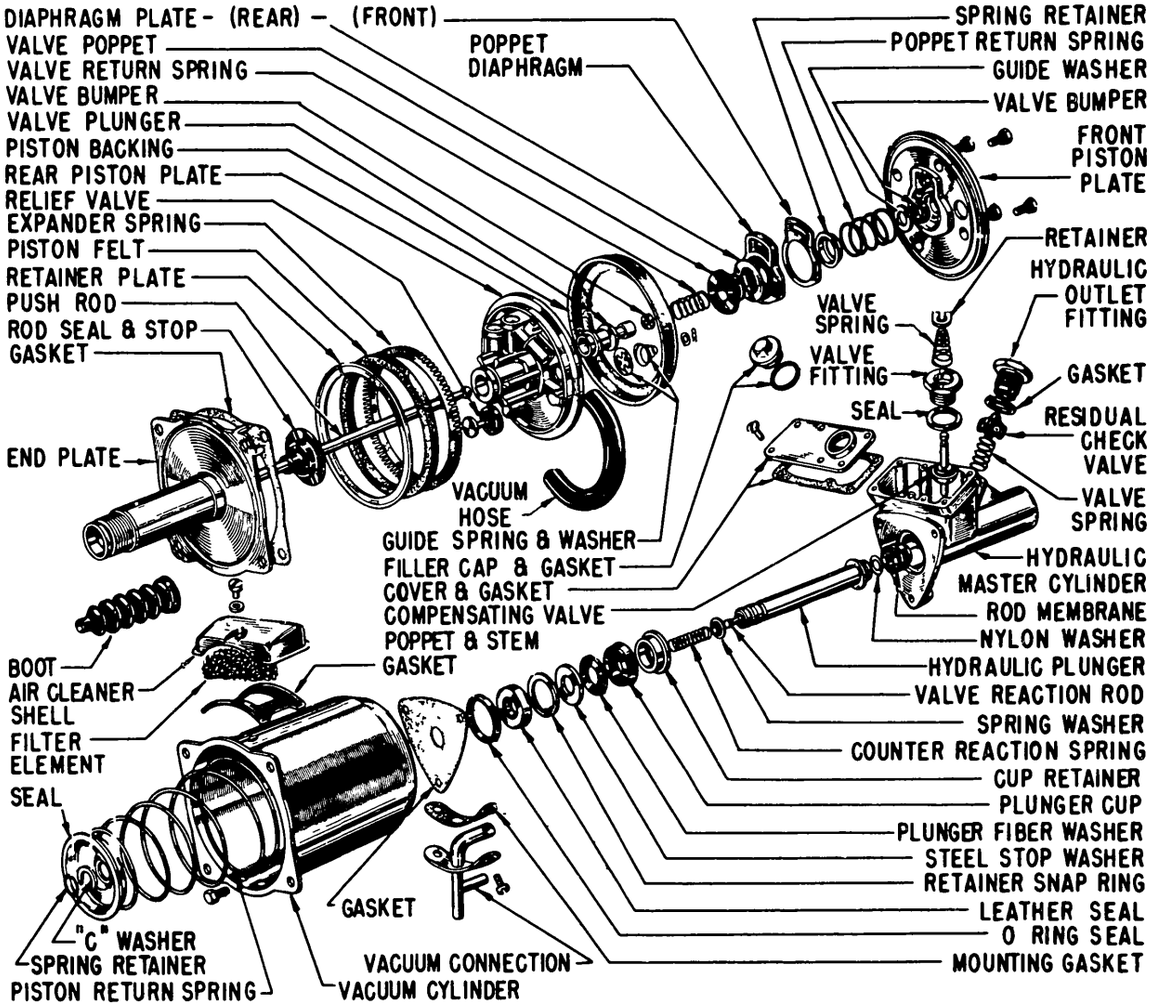
►CHANGES, CAUTIONS, CORRECTIONS

►*1958 EDSEL POWER BRAKE PUSHROD NON-INTERCHANGEABILITY CAUTION:* Different pushrods used as listed below. DO NOT INTERCHANGE as brakes either would drag or there would be insufficient pedal travel.

Ranger & Pacer - Part No. B8E-2005-A, identified by E-1 stamped on end of master cylinder body. Pushrod length, measured from end of mounting plate to center of pushrod eye, is 5 7/16".



Corsair & Citation - Part No. MG-2005-A, identified by M-5 stamped on end of master cylinder body. Pushrod length, measured from end of mounting plate to center of pushrod eye, is 4 29/32".

►*1958 EDSEL & MERCURY VACUUM CHECK VALVE STICKING IN COLD WEATHER CORRECTION:* Install new design check valve, Part No. MK-22049-A. Install by cutting off 3" (Edsel), 3¼" (Mercury) of vacuum hose, attaching short piece of hose to power brake, and inserting check valve between hoses with new clamps, Part No. B5A-2344-A.

►*1957-58 MERCURY POWER BRAKE AUTOMATIC APPLICATION OR FAILURE TO RELEASE CORRECTION:* This condition may be caused by an inverted brake booster mounting bracket. When properly positioned, small end of "pear shaped" opening in bracket should face downward.

DESCRIPTION: The Bendix "hydraulic reaction" type power unit is similar in design to previous Bendix units having the vacuum piston balanced in atmospheric pressure (both sides of the vacuum piston are open to atmospheric pressure when in the released position). A new "hydraulic reaction" feature transmits changes in hydraulic pressure to the vacuum valve through a reaction rod and rod membrane and provides the operator with a more definite brake "feel".

OPERATION: In the applied position, atmospheric pressure is blocked off from the forward side of vacuum piston as the valve plunger contacts the floating valve. Further movement of valve plunger pushes the floating valve from its seat in vacuum piston and permits vacuum to be connected to forward side of the vacuum piston. Atmospheric pressure on rear side of piston then moves piston and hydraulic plunger in the applied direction. The hydraulic plunger initial movement causes the compensating valve to close, sealing off fluid reservoir from the hydraulic cylinder. Further movement of the plunger in the applied direction increases pressure in master cylinder and forces fluid past the residual check valve and into the hydraulic lines. As fluid pressure is increased in master cylinder, a reaction force is transmitted to the reaction rod through the plunger seal (membrane) to overcome counter-reaction spring pressure and move valve plunger away from the floating valve. This allows the vacuum port to close and the atmospheric port to reopen, resulting in a reaction force which is in proportion to pressure in master cylinder and brake lines.

BENDIX VACUUM POWER BRAKE ASSEMBLY (WITH "HYDRAULIC REACTION" CONTROL)

►*POWER BRAKE UNIT REMOVAL NOTE: The complete unit must be removed from car as an assembly.*

►*POWER BRAKE UNIT OVERHAUL CAUTION: Use extreme care to prevent the natural rubber parts in unit coming in contact with mineral oil, grease, gasoline or cleaning solvent. Clean exterior of unit thoroughly before disassembly and make sure that solvent is not allowed to enter unit.*

DISASSEMBLY: (End Plate & Air Cleaner) - With unit in Holding Fixture J-5433, or hydraulic cylinder end clamped in vise, remove rubber dust guard and felt from valve pushrod (a drop of brake fluid on end of pushrod eye will permit removal of guard without damage). Bend out tabs on end plate and remove end plate and gasket. Slide vacuum hose off tube attached to vacuum cylinder. Remove air cleaner attaching screw and remove shell, hair and rubber seal. (*NOTE* - Remove any burr inside cylinder at air cleaner screw hole to prevent damage to packing during removal).

Vacuum Piston & Valves: Remove tube and plate attaching screws, tube and plate and gasket. Pull out vacuum

CONTINUED ON NEXT PAGE

BENDIX POWER BRAKE UNIT "HYDRAULIC REACTION" TYPE (C ntinued)

piston and valve assembly from cylinder. Remove counter reaction spring and washer from end of hydraulic plunger, then remove "O" ring seal from groove in hydraulic plunger.

Piston R turn Spring: Push in on spring retainer plate to release "C" washer. While holding spring compressed, slide "C" washer out of groove in hydraulic plunger. Remove retainer plate and vacuum piston return spring.

Vacuum & Hydraulic Cylinder: Scribe line across hydraulic master cylinder and vacuum cylinder. Remove three vacuum cylinder attaching screws and lockwashers. Lift off vacuum cylinder, vellumoid gasket and rubber ring gasket. Push hydraulic plunger into master cylinder and remove leather seal from cylinder.

Plung r Seal, Plat & Valv Cover: Scribe a line across master cylinder and cover. Remove filler cap and remove cover attaching screws and gasket. Remove compensating valve (using 1 1/8" "thin wall" socket). Loosen outlet fitting *(CAUTION - Do not remove outlet fitting at this tim)*. Remove retainer ring. Pull hydraulic plunger out of master cylinder and remove steel washer, fibre washer, rubber cup and cup retainer from plunger. Remove membrane seal, and nylon gasket from plunger.

R sidual Ch ck Valv : Remove outlet fitting from master cylinder then remove residual check valve spring, valve cup and retainer. Remove gasket from fitting.

C mp nsating Valv : Clamp compensating valve fitting in vise and spread and remove spring retainer, then remove spring, valve stem and poppet and fitting gasket from valve fitting.

Piston: Remove valve rod seal and stop from piston and piston rod. Remove vacuum hose from piston assembly. Remove retainer plate felt and expander spring. Hold rear piston plate in vise and remove four capscrews, front piston plate, diaphragm plate and poppet return spring. Remove diaphragm parts as an assembly and then separate these parts. Lift off leather piston packing and valve return spring. Remove rubber bumper (using a sharp pointed instrument from end of valve plunger), seal and fibre washer from piston plate. Remove valve operating rod and valve plunger from piston. *(NOTE* - If valve operating rod or valve plunger are to be replaced, inject alcohol in valve plunger opening around the valve operating rod to remove rubber lock. Hold valve operating rod in vise and drive valve plunger off operating rod using a ¾" wrench or similar tool against valve plunger).

CLEANING & INSPECTION: Wash all rubber or parts containing rubber in alcohol. Blow all parts dry with air. Remove rust or corrosion from bore of vacuum cylinder with fine emery cloth. Inspect all parts for wear or damage and replace all parts that are cracked, pitted, scored, scratched or corroded. Make sure that valves and valve seats are sealing properly and are not pitted or damaged. *CAUTION - Do not attempt to refinish bore or plunger of master cylinder.*

REASSEMBLY: *NOTE - Before assembly, dip all hydraulic system parts in clean alcohol and place in a clean pan or on a clean paper.*

Residual Check Valve: Assemble new gasket over threads of hydraulic outlet fitting. Hold fitting in vertical position and insert cone end of cup and retainer in fitting. Place check valve spring in recess in retainer. Hold hydraulic master cylinder upside down and thread outlet fitting into hydraulic master cylinder hand tight.

Compensating Valve: Insert grooved end of valve poppet and stem through hole in fitting from threaded end. Assemble large diameter end of spring over stem, holding poppet valve on seat. Compress spring and assemble retainer washer in groove of valve stem. Squeeze ends of washer together with pliers. Assemble new gasket over threads of compensating valve fitting.

Plunger Seal, Plate and Valve Cover: *With master cylinder in vise, assemble nylon washer and rubber membrane at end of hydraulic plunger. Insert membrane end of plunger in cylinder and assemble seal parts with seal installer Tool J-5405 over end of plunger as follows:* Cup retainer (with counterbored side away from washer on plunger), cup, fibre washer, and steel washer. Slide seal parts into recess of cylinder, push plunger in to end of its stroke and assemble retainer ring in ring groove. Assemble compensating valve in threaded hole in cylinder and securely tighten. Place new gasket on master cylinder, align cover to scribe marks, replace and securely tighten. Tighten outlet fitting securely.

Vacuum & Hydraulic Cylinder: Pull out hydraulic plunger, then, with seal installer Tool J-5405 placed over end of plunger, assemble leather seal over seal installer with lip of leather toward hydraulic master cylinder. Press seal into recess of master cylinder and then remove seal installer. Place "O" ring seal in recess in master cylinder. Insert three capscrews through holes in end of vacuum cylinder and holes in gasket. Align vacuum cylinder, gasket and master cylinder to scribe marks and tighten sapscrews securely. Wipe out vacuum cylinder, pull master cylinder plunger to end of stroke.

Piston Return Spring: Place large diameter end of vacuum piston return spring in vacuum cylinder and assemble retainer plate over end of hydraulic plunger. Compress spring and assemble "C" washer in inner groove of plunger.

Piston: If valve rod and valve plunger are separated, dip valve plunger in alcohol before inserting valve rod. Make certain ball end of rod is locked in place in valve plunger. It may be necessary to tap end of valve rod to seat ball end in valve plunger. Insert bumper in end of valve plunger, insert valve plunger assembly into rear piston plate, and assemble spring over end of plunger. Assemble leather packing on piston with lip side down. Assemble diaphragm plate in groove of diaphragm then assemble diaphragm over shoulder of poppet valve. Place this assembly in recess in piston plate and assemble spring retainer and diaphragm plate in diaphragm. Assemble poppet return spring over flange of spring retainer. Remove burrs from center bore of front piston plate and assemble seal and fibre washer in recess of front piston plate. Stake in place at three points. Place front piston plate on rear piston plate, making certain by-pass holes are properly positioned, and loosely assemble four attaching capscrews. Place assembly ring J-5406 over piston leather and turn piston assembly upside down. Assemble expander spring against inside lip of leather packing. Dip felt in Bendix Vacuum Cylinder Oil and assemble on expander spring. Assemble retainer plate making certain plate is securely anchored in grooves of four projections of piston assembly. Tighten four attaching capscrews securely and remove assembly ring J-5406. Assemble vacuum hose on piston. Dip valve pushrod seal and bumper in brake fluid and assemble over end of valve pushrod making certain seal is seated in groove in piston assembly.

Vacuum Piston in Cylinder: Apply thin film of vacuum cylinder oil to inside of cylinder. Assemble "O" ring seal in groove of hydraulic plunger, then assemble counterreaction spring and washer in recess at end of plunger. Insert piston in cylinder. When end of hose lines up with elongated hole, assemble new gasket, tube and plate and attach with screw. Slide end of hose on vacuum tube approximately 5/8". Operate piston through its full stroke several times to make certain vacuum hose does not rub against cylinder or piston.

End Plate & Air Cleaner: Assemble rubber seal on edges or air cleaner shell. Attach air cleaner to vacuum cylinder using screw and gasket. With 6" scale, push hair into open spaces at each end of air cleaner. Align holes on end plate and gasket with holes in flange of vacuum cylinder and bend over two tabs of end plate to secure end plate and gasket to cylinder. Assemble pushrod felt in second fold of rubber guard. Dip small end of guard in brake fluid and assemble guard and felt over pushrod. Attach lip of rubber guard over "scallops" at center of end plate.

►CHANGES & CORRECTIONS

►*1959 INSUFFICIENT POWER BRAKE CORRECTION:* Loss of power assist is caused by a vacuum leak in the system, either in external components or within the unit. If all external hoses and connections are found to be in good condition, remove power brake assembly from car and remove the end plate. Check internal vacuum hose for leakage and repair as necessary. Check retaining ring on piston assembly which is under the six bosses on piston assembly. If retainer ring is out of position, replace it under the bosses, then decrease ring diameter by gripping it between any two of the bosses with needle nose pliers and twisting to the right until ring is bent. Regrip ring at outer edge of the bent section and twist to left until ring is again flat. A slightly raised section formed by the bends will decrease ring diameter enough to hold it in position under retainer bosses.

►*1960 CADILLAC POWER BRAKE PRODUCTION CHANGE:* Beginning with Engine No. 099805, a new Bendix Power Brake Unit used in production. The new unit, identified by the Code CA-1 stamped on flange of vacuum cylinder sleeve, has been redesigned to give a more definite pedal response and return action. Power piston valve components are different than earlier type units and the piston plates are made of plastic, replacing former die-cast plates. Disassembly procedures are different as indicated below.

DESCRIPTION: This new Bendix Power Brake unit has the vacuum piston balanced in atmospheric pressure (both sides of vacuum piston are open to atmospheric pressure when in released position). The hydraulic reaction feature of this unit transmits changes in hydraulic pressure to the vacuum valve through a new type "reaction disc" (replacing the former reaction diaphragm on earlier models). On all models except Edsel, the master cylinder is the conventional piston type which is similar in design to master cylinders used on cars without power brakes. A plunger (displacement) type master cylinder of same design used on earlier Bendix units used on Edsel models.

BENDIX "HYDRAULIC (DISC) REACTION" POWER BRAKE UNIT

OPERATION: In the applied position, atmospheric pressure is blocked off from the forward side of vacuum piston as the valve operating rod forces valve plunger forward into contact with the poppet valve. Any additional movement of valve operating rod and valve plunger in the apply direction moves the poppet valve away from vacuum valve seat to open the vacuum port and establish direct contact through power piston and valve to hydraulic master cylinder. With vacuum on forward side of power piston, atmospheric pressure on rear side of piston moves the power piston. This movement carries hydraulic pushrod and piston forward to close compensating port and force hydraulic fluid under pressure through the residual pressure check valve and brake tubes into wheel cylinders. As hydraulic pressure is developed, the load in the hydraulic pushrod increases correspondingly and in effect pushes back against the reaction disc. The soft rubber reaction disc bulges through the small hole in center of power piston and presses on end of valve plunger. The hole is so small only a fraction of the reaction force finds its way back through linkage and pedal to driver's foot.

REMOVAL: Power Brake & Mast r Cylind r - Disconnect clevis at brake pedal assembly, then remove vacuum hoses from brake unit and hydraulic line from master cylinder. Remove nuts and lockwashers attaching unit to firewall and remove unit.

Master Cylinder (Exc. Edsel): *NOTE - Master cylinder can be removed on all cars (Except Edsel) without removing power brake assembly from car.* Disconnect hydraulic line from master cylinder and remove nuts and bolts securing master cylinder to power brake unit. *CAUTION - Keep area around pushrod clean.*

Edsel - Power brake assembly must be removed from firewall and disassembled for removal of master cylinder assembly.

►*POWER BRAKE DISASSEMBLY & OVERHAUL CAUTION: Use extreme care to pr vent natural rubber parts in unit from coming in contact with mineral oil, gr as , gasoline, or cleaning solv nt. Clean exterior of unit thoroughly before disassembly and make sure that solvent is not allowed to enter unit.*

DISASSEMBLY: Power Brak Unit - Remove master cylinder from power brake unit (except Edsel). *NOTE - Master cylinder on Edsel models will be removed after vacuum cylind r is removed from power brake unit.* Pull master cylinder pushrod from vacuum unit (DO NOT

CONTINUED ON NEXT PAGE

BENDIX "HYDRAULIC (DISC) REACTION" TYPE (C ntinued)

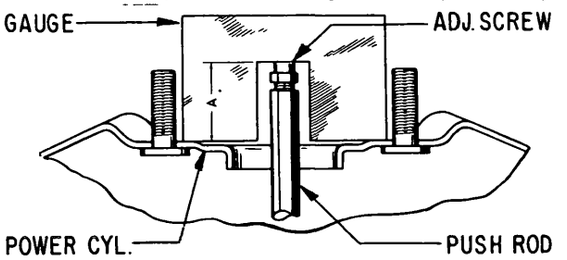
DISTURB adjustment screw at end of pushrod). Remove dust guard from endplate and valve operating rod, then scribe a line across endplate and vacuum cylinder to insure proper reassembly. Remove six endplate attaching screws, then press down on endplate while removing the other two. Scribe a line across face of piston to register with scribe marks on endplate and vacuum cylinder. Disconnect vacuum hose from vacuum inlet tube and remove endplate, vacuum piston and piston return spring. Remove screws holding air cleaner to endplate and remove air cleaner.

Vacuum Pist n: (Di -Cast Type) - Spring the felt ring to disengage ring from grooves in bosses in rear piston plate, then remove piston felt and expander ring from piston assembly. Remove piston plate attaching screws and separate front plate and piston packing from piston plate. Remove valve return spring, poppet and diaphragm assembly, poppet spring and poppet support plate. Separate poppet spring retainer and poppet diaphragm from poppet. Remove rubber reaction disc from front piston plate. *NOTE - It may be necessary to use a small rod having a smooth flat end to push reaction disc out of piston.* DO NOT REMOVE valve operating rod and valve plunger from rear piston plate unless it is necessary to replace because of damaged or worn parts. If it is necessary to remove either the valve operating rod or valve plunger, remove valve rod seal from groove in piston plate and pull seal over end of rod. Holding piston with valve plunger down, inject a small amount of alcohol in valve plunger, through off valve rod. On Edsel models, remove screws attaching master cylinder to vacuum cylinder and remove master cylinder.

(Plastic Typ Piston) - Remove felt &ring from piston assembly, then lift rod seal and bumper boot from rear piston plate and slide off eye end of operating rod. Remove capscrews from front piston plate, separate front and rear piston plates, and remove leather packing. Remove poppet spring, valve, return spring retainer, poppet diaphragms, poppet, poppet spacer, and plunger and rod assembly. *NOTE - Do not separate valve op rating rod from valv plunger unless replacement of valv rod or plung r is necessary.* If valve rod or plunger must be replaced, hold assembly with valve plunger down and inject alcohol into cavity around valve rod to wet rubber lock in valve plunger, then drive or pry valve plunger off valve rod. Use care not to damage plunger if it is to be reused. Remove rubber reaction disc from front piston plate if necessary.

CLEANING & INSPECTION: Wash all parts in alcohol and blow dry with air. *CAUTION - Do not handle hydraulic parts with greasy hands.* Remove rust or corrosion from bore of vacuum cylinder with fine emery cloth. Inspect all parts for wear or damage and replace all parts that are cracked, pitted, scratched or corroded. Make sure that valves and valve seats are seating properly and are not pitted or damaged.

REASSEMBLY: (Die-Cast Piston) - If valve operating rod and valve plunger were separated, position valve rod seal over valve operating rod, then insert valve rod through piston. Dip valve plunger in alcohol and assemble to valve end of rod. *NOTE - Be sure ball end of rod is locked in position in valve plunger. It may be necessary to tap end of valve operating rod to seat ball end in plunger.* Assemble poppet diaphragm over end of poppet, being sure diaphragm is in recess of poppet, then press poppet spring retainer over end of poppet and diaphragm. Clamp valve operating rod in vise with rear piston plate up and lay leather piston packing on rear plate with lip of leather over edge of plate. Install valve return spring over end of valve plunger. Assemble diaphragm support plate in relief of diaphragm and assemble poppet with diaphragm and plate in recess of rear plate. Install poppet spring over retainer. Align and assemble front piston plate with rear piston plate. Center poppet spring on front piston plate and center valve plunger stem in hole of piston. Hold front and rear piston plate together and install six piston plate capscrews, leaving them loose. Insert rubber reaction disc in recess in center of front piston plate. Place piston on bench with valve operating rod up and place expander ring against inside lip of leather packing. Saturate felt in clean shock absorber fluid, letting excess drip off, and position felt in expander ring. Assemble retainer ring over bosses on rear piston plate, being sure retainer is anchored in grooves of piston plate. Tighten the six retaining screws securely. *NOTE - If retainer ring is not a tight fit in bosses of rear piston plate, see "Insufficient Power Brake Assist Correction" above for procedure to be used to tighten retainer ring.*



(Plastic Type) - Place plunger and rod assembly into rear piston plate, and install rod seal and bumper boot. Position spacer washer into cavity inside rear piston plate, then assemble poppet through poppet diaphragm, and install poppet spring retainer on end of poppet. Position leather packing on rear piston plate, then install poppet spring and valve return spring on plunger and poppet reaction plate. Postiion and align front piston plate against rear piston plate, and secure in position with capscrews. Soak piston felt in shock absorber fluid, then insert felt in expander ring, and position expander and felt in groove around rear piston plate with expander teeth up.

Power Brak Unit: Assemble air cleaner element over vacuum tube of air cleaner and attach assembly to end plate with two screws. Slide vacuum hose onto vacuum tube inlet of air cleaner assembly, then install pushrod. *CAUTION - Be sure rubber reaction disc is in place in front piston plate.* Apply a thin coat of shock absorber fluid to base of vacuum cylinder and to piston leather. *NOTE - On Edsel, install brake master cylinder on vacuum cylinder.* On all cars, center small diameter of piston return spring in vacuum cylinder with large diameter facing piston then insert vacuum piston into cylinder, aligning scribe marks on end plate and vacuum cylinder. Position vacuum hose so it lays flat against piston and does not rub on cylinder. Compress piston return spring by pressing down on piston and install two screws at opposite side of end plate to secure it to cylinder. Install remaining screws and tighten securely. Dip small diameter of dust boot in alcohol and assemble boot over end of operating rod and flange on end plate.

Pushrod Adjustment (Exc. Lincoln): *NOTE - The self locking screw on end of pushrod is set to correct height on original assembly and adjustment is not required unless hydraulic pushrod has been replaced, or if adjustment has been changed. If necessary, adjust as follows:* With piston assembly free in cylinder and firmly seated in a released position, hold pushrod seated against reaction disc and centered in spring of master cylinder. Use Gauge indicated in table below or measure distance from mounting face of power cylinder to end of pushrod adjustment screw (see table for correct dimension). Rotate adjusting screw as necessary to obtain correct adjustment.

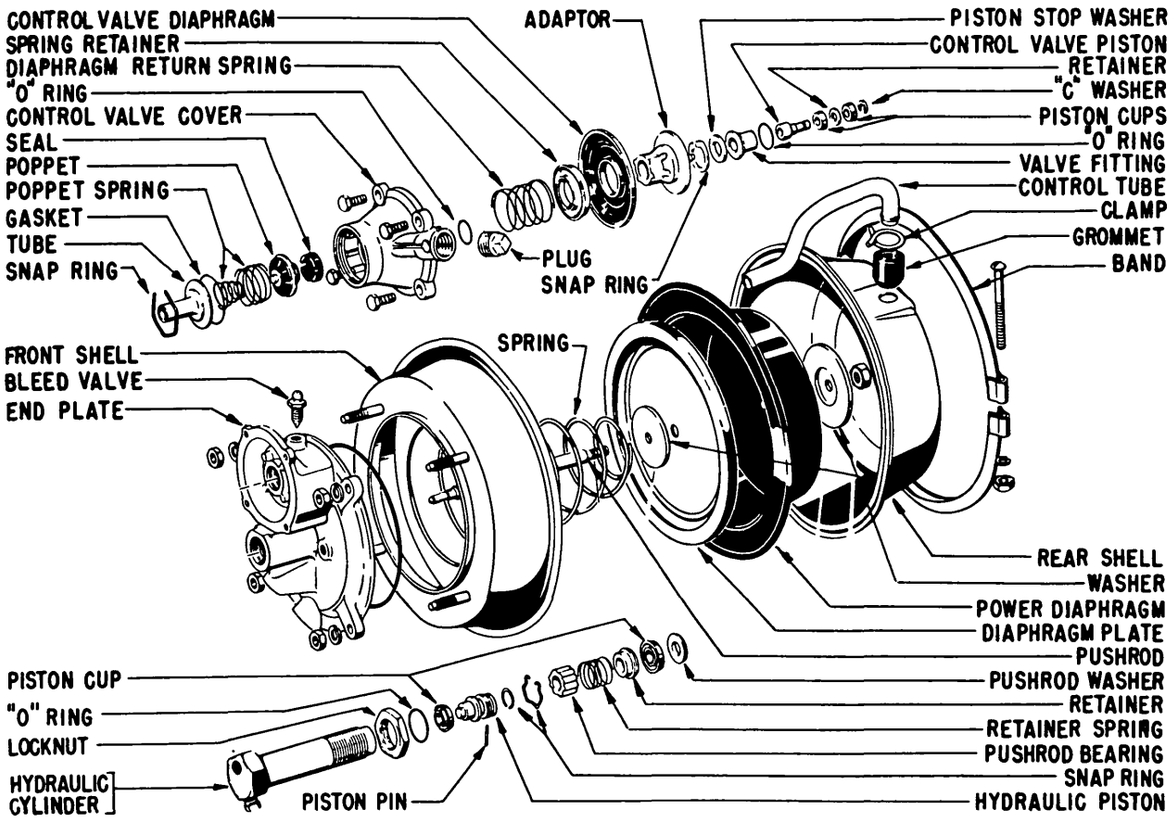
Model	Pushrod Adjustment Gauge No.	Dimensi n
Cadillac	J-7723	1.195-1.200"
Chevrolet	J-7723	1.195-1.200"
Ford		.962-.967"
Edsel, Mercury		.993-.998"
Oldsmobile	J-7723	1.195-1.200"
Pontiac	J-7723	1.195-1.200"
Valiant	C-3815	1.195-1.200"

INSTALLATION: Reverse removal procedures (see above).

PUSHROD ADJUSTMENT

HYDROVAC POWER UNIT (DIAPHRAGM TYPE)

Ch vrolet Truck, Series 40, 50, 60 (1960)



DESCRIPTION: This vacuum operated unit is connected in the brake hydraulic line between master cylinder and wheel cylinders and is controlled by brake master cylinder pressure.

►*BLEEDING BRAKES CAUTION: Before bleeding brakes on models with Hydrovac units, the manually p rated bleed valve located on end of slave cylinder must be opened. Engine must be shut off and there must be no vacuum in the power system.*

DISASSEMBLY: Scribe a line across both halves of vacuum chamber and across end plate and front chamber. Remove clamp, control tube, and rubber grommet from rear vacuum chamber half, then remove clamp screw, clamp band, and rear vacuum chamber. Compress diaphragm return spring and hold spring compressed with clamping tool while removing hydraulic cylinder tube, then remove piston retainer pin and hydraulic piston assembly. Release return spring and remove diaphragm, pushrod assembly, and diaphragm return spring. Remove cup from hydraulic piston. *NOTE - A holding fixture to hold spring compressed while removing hydraulic cylinder and piston can be made from a piece of 3/16" x 1½" x 12" strap and two hook bolts.* To disassemble control valve and piston fitting, remove snap ring, tube, gasket, valve poppet springs, valve poppet, and vacuum poppet seat from valve cover. Remove four valve cover screws, valve cover, diaphragm return spring, spring retainer, diaphragm, and valve diaphragm adaptor. Remove retainer ring, stop washer, and valve piston fitting. Remove "O" ring seal from fitting and press out piston assembly. Remove "C" washer, cups, and cup retainer washer from piston. Remove bleed valve and control valve housing. Remove pushrod seal parts and end plate from diaphragm housing as follows: Remove hydraulic cylinder end seal from center bore of end plate, then remove retainer snap ring, pushrod bearing, spring, cup retainer, cup, and pushrod washer. Remove four end plate attaching nuts and lockwashers and remove end plate from front vacuum chamber half, then remove gasket from end plate. To remove diaphragm from pushrod, clamp pushrod in vise next to diaphragm (use soft vise jaws), then remove nut, diaphragm retaining washer, diaphragm, diaphragm plate, and pushrod.

INSPECTION: Wash all parts in alcohol and blow dry with air. *CAUTION - Do not try to clean small passages with drills or wire.* Check condition of diaphragm and pushrod. Diaphragm must be free of cracks or flaws and pushrod must be smooth. Do not use pliers on pushrod. Inspect slave cylinder casting for scores, pitting or roughness. Make sure there are no dents in vacuum chamber halves.

REASSEMBLY: Clamp pushrod in vise near threaded end (use soft vise jaws), then assemble pushrod washer, diaphragm plate, diaphragm, diaphragm retaining

HYDROVAC POWER UNIT ASSEMBLY (DIAPHRAGM TYPE)

washer and nut. Securely tighten nut and stake in three places. Place end plate gasket in groove (outer) of end plate and assemble end plate to front diaphragm chamber. Align end plate and housing to scribe marks, then assemble pushrod washer in center bore of end plate, beveled side first, flat side next to washer; cup retainer, shoulder side against cup; spring; pushrod bearing; and retainer snap ring. Make sure retainer ring is in inner ring groove. Assemble hydraulic cylinder "O" ring seal in outer groove of end plate. Dip control valve piston cups in brake fluid and assemble on piston with lip of cups away from hole end of piston and with cup retainer washer between cups. Replace "C" washer and squeeze ends of washer together after assembly to piston. Dip piston assembly in brake fluid and insert piston in fitting (as indicated in illustration). Place seal on fitting and insert fitting with piston in hole of end plate. Replace stop washer and retainer snap ring. Assemble control tube seal in recess of control valve housing, then assemble diaphragm and spring retainer on valve diaphragm adaptor. Place diaphragm return spring in position on retainer and attach control valve cover, making sure all parts are assembled to scribe marks. Assemble vacuum poppet seat over end valve poppet and assemble in housing. Replace valve springs (large and small) with small diameter end of spring over button of poppet valve. Place cover gasket in recess of housing and attach tube with snap ring. Assemble hydraulic cylinder, piston, vacuum piston return spring, and vacuum diaphragm as follows: If nut was removed from hydraulic tube, replace nut on tube to limit of threads. Dip piston cup in brake fluid and assemble cup on piston with lip of cup toward hydraulic cylinder. Place small diameter end of diaphragm return spring over spring retainer washer on diaphragm, then guide end of pushrod through stationary seal in end plate. Compress and hold spring sufficiently to project pushrod through end plate. Attach hydraulic piston assembly to end of pushrod with retainer pin and hold pin in place with retainer ring. Carefully guide hydraulic cylinder tube over hydraulic piston and cup, being careful not to damage cup. Thread cylinder into end plate hand tight, then release pressure against diaphragm return spring and remove holding fixture. Assemble rear diaphragm chamber half in position on diaphragm with rear and front chamber halves aligned to scribe marks. Assemble clamp band over rim of front and rear halves and bead of diaphragm, then securely tighten band nut. Assemble rubber grommet in rear shell (wet with brake fluid to aid in assembly), then insert control tube in grommet and replace hose clamp. Align hydraulic cylinder assembly in end plate so that shutoff valve in end cap is at bottom, then securely tighten check nut.

HYDROVAC POWER UNIT "PISTON TYPE"

Buick (1956 Optl.)

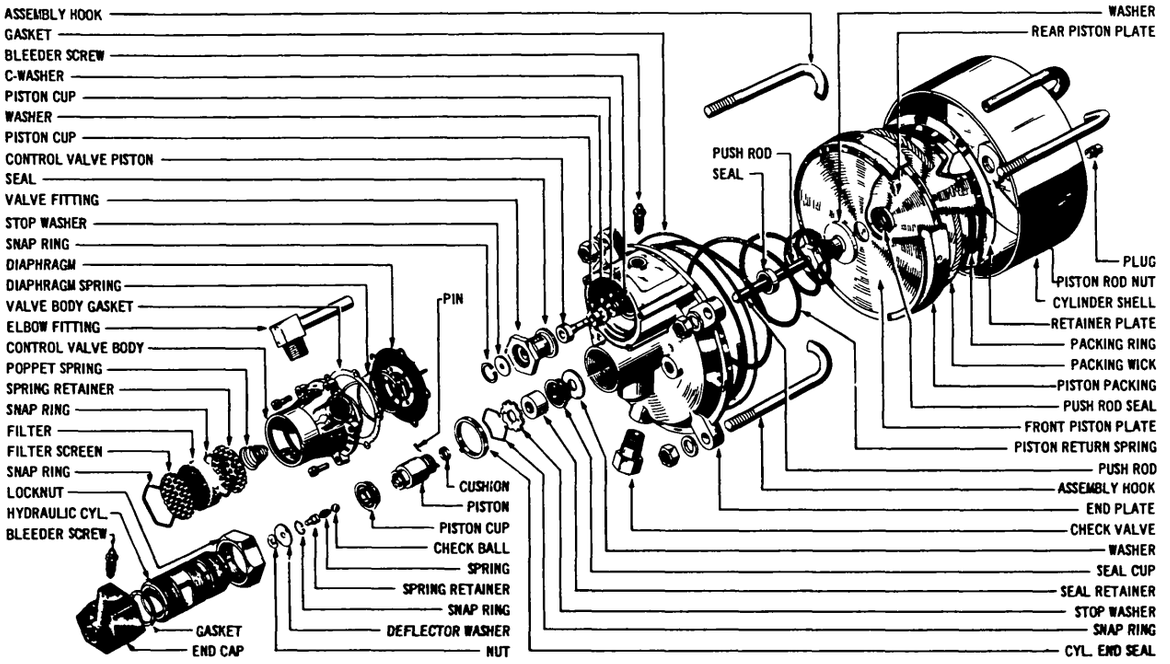
Willys (1957-60)

Ⓒ - Midland Hi-Power also used

►CHANGES & CORRECTIONS

►*1954 CADILLAC ACTUATING PISTON & CYLINDER ASSEMBLY PRODUCTION CHANGE:* **Starting with Engine Serial No. 54038 a new 3/8" Actuating Piston and Cylinder Assembly entered production replacing the earlier 5/16" piston and cylinder. Units with the later type piston and valve are identified by the number 377144 stamped on the brass identification tag. Units with the 5/16" assembly have number 376755 (production units), 376930 (replacement units) stamped on identification tag.**

►*1955 CADILLAC PRODUCTION CHANGES* The following changes over previous models have been made in 1955 production **(1)** ½ diameter control valve piston replaces smaller piston formerly used, thereby reducing pedal pressure required for brake assist **(2)** Use of a smaller master cylinder boot and pedal shaft seal at toe-board ,have eliminated need for brake pedal retracting spring **(3)** Residual check valve, formerly located in master cylinder, is now located in hydraulic cylinder end cap on power assembly



►*1955 CHEVROLET PRODUCTION CHANGE* Beginning with 2nd Series (Except Low Cab Forward) residual check valve has been incorporated in hydraulic cylinder end cap on power assembly

►*1955 STUDEBAKER CONTROL VALVE PRODUCTION CHANGE (To Provide Softer Brake Fedal)* Beginning Serial Nos G-1334649 (16G6), 8403935 (16G8), 7160012 (6HY), and 7160032 (6HC & K), a 7/16 control valve is used in place of 3/8 control valve formerly used Kit, Part No 537939, available to make installation on earlier cars *CAUTION*–7/16 conversion kit is for use on 1955 Models **with factory installed** Power brake units only it is not recommended for installation on any car with power brakes having the high (7 1 ratio) brake pedal

►*1956 CHEVROLET TRUCK HYDROVAC POPPET VALVE PRODUCTION CHANGE* Repair Kit No. 2214318 consisting of large poppet valve, small poppet valve, lead gasket and screw, when installed, eliminates the need to replace Hydrovac control cover and poppet valve as an assembly, when poppet valve failure is encountered.

R m val & Installati n – 1) Remove poppet valve by inserting an offset open end wrench or small pry bar behind the large poppet valve to pry out rivet retaining smaller valve, or support valve body on two wood blocks and drive out poppet shaft with punch.

2) Assemble above parts, being sure lead gasket is behind small poppet, before starting screw into large poppet.

HYDROVAC BRAKE POWER UNIT

3) Hold shaft with pair of thin offset pliers and tighten screw securely.

DESCRIPTION· Bendix HYDROVAC Power Unit connected in hydraulic brake line between master cylinder and wheel cylinders (no mechanical connection)

OPERATION: As brake pedal is depressed, hydraulic pressure developed in master cylinder is transmitted to power brake hydraulic cylinder and to hydraulic piston in vacuum control valve. As hydraulic piston in power brake hydraulic cylinder is against stop washer when pedal is first depressed, check ball in piston is held off its seat by piston yoke. This allows fluid from master cylinder to pass through piston directly to wheel cylinders. This feature permits normal operation of brakes when engine is not running. Fluid under pressure is also directed to hydraulic piston in vacuum control valve. As fluid pressure moves this piston, it actuates vacuum diaphragm control shaft and forces diaphragm against vacuum poppet valve sealing off atmospheric side of diaphragm from manifold vacuum. Continued movement of piston and diaphragm forces atmospheric poppet valve off its seat and admits air under atmospheric pressure to vacuum piston.

BLEEDING BRAKES (Except Cadillac) *(CAUTION– This operation must be done with engine stopped and no vacuum in the power brake system)* Attach bleeder hose to bleeder valve on control body keep end of drain hose below surface of fluid in drain jar Loosen bleeder valve ½-¾ turn Depress brake pedal slowly by hand to expel air When pedal has reached toe board, close bleeder valve before returning pedal to released position Repeat this procedure until air bubbles cease to appear at the end of the bleeder drain hose in the jar and the stream is a solid fluid mass then tighten bleeder valve and remove drain hose *(NOTE–***During the operation the brake master cylinder must be fill d with fluid)** Following above procedure, bleed at bleeder valve on end cap of hydraulic cylinder, then proceed to bleed wheel cylinders in the usual manner

BLEEDING BRAKES (Cadillac)· Use same procedure as described above for cars other than Cadillac, except as follows Bleed valve on end cap of hydraulic cylinder first, then valve on control valve body

LUBRICATION Remove screw plug on front end of vacuum cylinder and fill cylinder to level of hole (Studebaker 1 oz) with Delco Shock Absorber Fluid or Bendix Hydraulic Cylinder Fluid as follows

Cadillac Once yearly
Chevrolet Every 10,000 miles
Ford & Studebaker Once yearly or every 20,000 miles

TROUBLE SHOOTING Before trying to determine cause of trouble make certain that master cylinder reservoir is full, that brake system is free of air that there are no binds in the brake linkage that there are no air or fluid leaks to the master and wheel cylinders Then proceed as follows

Hissing Sound (Engine Running), Brakes Either On r Off· Caused by external leak on vacuum side of control diaphragm Check and correct leak at control valve body, diaphragm, and gasket to end plate Check and correct leak between vacuum cylinder and end plate

CONTINUED ON NEXT PAGE

HYDROVAC POWER UNIT "PISTON TYPE" (Cont.)

Hissing Sound (Engine Running), Greater When Brakes Off: Caused by external leak on atmospheric side of control valve diaphragm Check and correct leak at atmospheric poppet, external pipe and rubber tubing, and valve body screws

Hissing Sound (Engine Running), Brakes On: Caused by internal vacuum leak, air entering through breather Overhaul unit and check for leak at vacuum poppet, control diaphragm, or vacuum power piston

Little or No Boost From Power Brake (May be Accompanied by a Hissing Sound or Loss of Brake Fluid):

1) Internal vacuum leak between atmospheric and vacuum side of power piston Overhaul unit, and check for leak at vacuum poppet, control diaphragm, or vacuum power piston

2) Internal hydraulic leak Check for low brake fluid level Overhaul unit and check for presence of brake fluid in inner side of vacuum cylinder, or inner side of control diaphragm Check and correct leaks at control valve cup, control valve fitting "O" ring seal, vacuum piston push rod seals, or hydraulic power piston cup or ball check

3) External hydraulic leak Check and correct leak at point of origin

4) Internal friction Check and correct shock absorber fluid level in vacuum cylinder If necessary, overhaul unit and check for rusty, dirty, or distorted vacuum cylinder wall, dry or worn vacuum piston leather packing, swollen rubber cups due to heat or wrong brake fluid, worn or damaged rubber cups, or dirt, rust, sludge, or foreign matter in power piston or control valve regions

Booster Loses Effectiveness While Stopping (Pedal Grows Harder or "Kicks Back"): Caused by internal hydraulic leak or internal or external vacuum leak Overhaul unit and check for leaks at control valve, valve fitting, power piston, vacuum poppet, control diaphragm, or vacuum power piston Check for sticking power piston, or restricted air cleaner (if so equipped)

Tendency To Over-Brake (Pedal drops under foot. May show up as slow operation of power brake): Restriction in atmospheric passage or sticky control valve Clean air filter for restriction in atmospheric passage If necessary, overhaul unit and check for misalignment of control valve assembly Check for dirty or sticky vacuum or atmospheric poppet as well as sticky control valve NOTE—Above condition may also be caused by internal hydraulic leakage or internal friction To correct, overhaul unit and check for leak at hydraulic power piston cup or ball check Check for binding in power piston assembly Check level of lubricant in vacuum cylinder

Brakes Slow to Release (or fail to release completely): May be caused by sluggish control valve action or internal friction. Overhaul unit and check for weak vacuum power piston return spring or atmospheric poppet return spring Check for dirty or sticky control valve Check for power cylinder lubricant level If necessary overhaul unit and check for binding in power piston assembly

No Power Assist (On first application after engine shut off): Caused by an external vacuum leak or an internal vacuum leak in the check valve Check and correct external leaks at valve body, external pipe, vacuum cylinder, and atmospheric poppet. For the internal leakage, overhaul or replace check valve assembly.

Brakes Apply When Engine Started Caused by broken or improperly assembled atmospheric valve return spring or control valve diaphragm return spring, sticking control valve piston

Air in Hydraulic System: Caused by an improperly assembled, defective or missing control valve piston secondary cup

Grabbing Brakes: Caused by sticking control valve piston or sticking power piston

Loss of Fluid from Brake System Caused by defective hydraulic cylinder cup or seal, defective or damaged control valve piston cup (crack or split in lip at center of cup), dirt chips or other foreign matter under lip of piston cups, improperly tightened or defective gaskets or rubber seals

Power Unit Fails to Operate Low or no vacuum due to clogged or restricted lines, defective check valve, clogged air filter (if so equipped)

REMOVAL OF POWER BRAKE UNIT: Disconnect brake lines at cylinder end plate Loosen vacuum line hose clamp at check valve and slide hose off Remove three nuts and lockwashers from cylinder mounting bracket and remove unit from car *NOTE*—Ford and Studebaker have stop light wires that must be disconnected before unit is removed

DISASSEMBLY OF POWER BRAKE UNIT: When disassembling Power Brake use care in handling parts to prevent their coming in contact with mineral oil or greases Do not handle hydraulic cups and seals with greasy hands

Hydraulic Cylinder Assembly: 1) Loosen the cylinder nut and unscrew hydraulic cylinder assembly from end plate Hold end cap in a vise and remove hydraulic cylinder from cap using an open end wrench on the flat part of cylinder Remove gasket and bleeder fitting from end cap

2) On 1954 Cadillac, Chevrolet 1955 1st Series and Earlier Trucks, and Studebaker, remove the bolt holding the hydraulic line end connection to the end cap and remove fitting and copper gaskets Scribe line on cylinder shell and end plate so these parts can be reassembled in their original positions Loosen hook bolts and remove cylinder shell, sliding tube out of rubber hose

3) On 1955 Cadillac, 1955 Chevrolet 2nd Series Trucks, and Ford, remove residual check valve snap ring, spring seat, spring and residual check valve Loosen hook bolts and remove cylinder shell, sliding connector pipe out of rubber hose

4) On all cars, compress piston spring by pressing down on end plate Hold piston in position with Vacuum Piston Retaining Strap, Tool J-5650 (two wire hooks and a plate can readily be made to hold piston in position) Remove hydraulic piston assembly from pushrod by holding retaining spring back and removing small pin Remove hydraulic piston cup from piston, remove snap ring, retainer, spring, and ball Remove hydraulic cylinder and seal Remove snap ring, then remove pushrod seal cup parts Drive out pushrod leather retainer with a flat end rod or drift

Vacuum Control Valve Assembly: 1) Scribe control valve body and end plate to insure proper location on reassembly Remove control valve body screws and remove control valve assembly with diaphragm and gasket Remove diaphragm from control valve body

2) On Cadillac and Studebaker, remove air intake filter snap ring, screen and filter, and take out lower snap ring and screen

3) On Chevrolet and Ford, remove snap ring which retains cover on control valve and poppet assembly and remove cover, valve spring and gasket,

4) On all cars, remove hydraulic control valve fitting from end plate Push piston out of fitting and remove cups from piston (washer between cups on Chevrolet and Studebaker) Remove seal, retainer ring, and stop washer from fitting

Vacuum Piston: Remove nut from threaded end of push rod, retainer plate, packing, and expander ring Remove small diameter piston plate with rubber seal ring Remove leather packing, larger diameter piston plate, and washer from push rod

Vacuum Piston Pushrod Assembly (Ford): Remove push rod lock ring from groove in piston guide Remove spring washer, then lift out pushrod, spring, bottom spring washer, and bottom lock ring

Vacuum Piston Pushrod Guide (Ford): Clamp hexagonal section of guide sleeve in a vise Remove guide sleeve to body gasket, washer, and nut Loosen outer locknut, then remove assembly from vise Remove locknut gasket, and guide sleeve Remove piston guide by drawing it into cylinder shell

Check Valve (Cadillac & Studebaker): Remove assy from elbow in end plate Remove plug from bushing and bushing from check valve assembly Remove snap ring, spring retainer, and spring with check ball Remove spring from check ball

REASSEMBLY OF POWER BRAKE UNIT: Before reassembling unit, clean all parts thoroughly, and after cleaning, wash all parts for hydraulic system in alcohol Be careful not to get grease or oil on hydraulic parts Use new rubber seals and cups when reassembling

Vacuum Piston: (*NOTE*—An assembly ring can be made by cutting a 1 section from end of a power cylinder) Place front (larger) piston plate in assembly ring with lip down Place new leather packing on plate with lip up, place new rubber seal in center of plate Install rear (smaller) piston plate with lip down Coil new wick inside lip of packing and cut it to proper size Soak wick in cylinder oil (not ordinary oil) and allow it to drain thoroughly Install wick Place packing ring inside wick with gripper points up, and engage notch at loop end of ring with hook at opposite end Install wick retainer plate with cutout portion over loop of expander ring Place flat washer over threaded end of pushrod (guide rod on Ford), insert pushrod (guide rod) through assembled piston parts, being careful not to damage inner seal ring Large piston plate should rest against flat washer Clamp hex on pushrod

CONTINUED ON NEXT PAGE

HYDROVAC POWER UNIT "PISTON TYPE" (C nt.)

(guide rod) in a vise, being careful not to damage polished surfaces. Install nut and tighten securely, being careful not to allow either piston plate to rotate while nut is being tightened Remove assembly ring Stake nut with center punch.

Pushrod Ass mbly (Ford)—Clamp hexagonal section of guide rod firmly in a vise Assemble pushrod attaching parts over beveled end of pushrod in following order Lock ring, one spring retainer, spring (large end first), second spring retainer, snap ring (smaller). Use care in assembling smaller diameter snap ring in groove at lower end of pushrod, to avoid distorting ring Insert end of pushrod in recess at end of guide rod. To attach pushrod to guide rod, compress spring and assemble to lock ring in groove of guide rod Be sure lock ring is firmly seated in groove of guide rod.

Vacuum C ntr l Valv Ass mbly: 1) Install stop washer and retainer ring in hydraulic control valve fitting. **2) On Ch vr l t and Stud baker,** dip piston cups in brake fluid and install on piston with washer between cups Install C-washer Lips of both cups must point away from end of piston with hole in it **3) On Cadillac and Ford,** install new rubber cups on piston with lip of cups toward small end of piston **4) On all cars,** install piston in fitting with hole in end of piston next to stop washer Install a new rubber seal gasket in groove in fitting. Install fitting in end plate and tighten securely. **5) On Cadillac and Stud baker,** install poppet return spring with small end down, retainer and snap ring in control valve body. Install new filter, screen and outer snap ring. **6) On Ch vr l t and F rd,** install poppet return spring with small end down, gasket, end cover with air inlet tube, and secure in place with snap ring. **7) On all cars,** place guide pins in control valve body screw holes in end plate (Guide pins can be made by cutting heads off three 8-32 x 2½" machine screws). Install gasket diaphragm, diaphragm spring (if so equipped), and control body on guide pins allowing cylinder tube to slide into connecting hose. *(CAUTION —When assembling diaphragm, spring, and control valve body, extreme care should be taken not to distort the diaphragm when compressing the spring).* Remove guide pins one at a time and install screws and lockwashers. Install hose clamps.

Cadillac Note—One side of valve body mounting flange is straight. This should be positioned next to hydraulic cylinder boss on end plate.

Hydraulic Cylinder Assembly: 1) Install new pushrod leather seal into end plate with lip of seal toward hydraulic cylinder side of end plate. Place end plate on bench and install stop washer with chamfered side down. Install seal cup with lip up and seal retainer with counterbored side next to cup (Cadillac & Studebaker), flat side next to cup (Chevrolet & Ford). **On Ford and Chevrolet,** next install spring with small end toward bore of end plate (No spring on Cadillac and Studebaker) **On all cars,** next install stop washer and install snap ring in groove.

2) Place vacuum piston return spring over pushrod with small end of spring next to piston, carefully guide pushrod through seat in end plate Compress spring. Use vacuum piston restraining strap or hook clamps to hold end plate and the cylinder together Install ball, spring, retainer and snap ring in piston. **On Cadillac and Studebaker,** install deflector washer and nut.

3) Dip hydraulic piston cup in brake fluid and install in groove with lip of cup toward check valve end of piston. Dip hydraulic piston in brake fluid and assemble piston on push rod. Install retaining pin in hole in piston and rod. When pin is in position, retaining spring will hold it in position. Place end cap in vise and install bleeder screw, end cap gasket, hydraulic line connector with copper gaskets and retaining bolt.

4) On 1955 Cadillac, 1955 Chevrolet 2nd Seri s Trucks, and Ford, install residual check valve, spring, spring seat, and snap ring.

5) Thread hydraulic cylinder into end cap with milled flats next to end cap, and securely tighten cylinder. Thread check nut on cylinder to limit of threads. Install hydraulic cylinder end seal against shoulder in end plate. Guide lip of piston cup into cylinder carefully, and threaded cylinder into end plate until cylinder bottoms firmly against end seal. Tighten cylinder until bleed screw on end cap is aligned with bleed screw in end plate and tighten check nut securely.

6) Remove piston retaining strap or clamps. Place rubber gasket in groove on end plate. Saturate cotton wicking by dipping vacuum piston in Shock Absorber Fluid, and allow excess oil to drain off. In addition, coat inside of cylinder shell lightly with shock absorber fluid. Insert piston into shell by tipping piston and gradually working it down into shell. Align scribe marks on shell and end plate (if made) and attach hook bolts. Tighten each bolt evenly until all bolts are uniformly tight.

Check Valve (Cadillac & Studebaker): Install end of spring over check valve ball. Install spring retainer plate with depression in plate in end of spring, install snap ring. Install plug in check valve body. Install fitting in bushing and install valve assembly in elbow on end plate.

INSTALLATION OF POWER BRAKE UNIT: Position power brake unit on mounting bracket and install lockwashers and nuts. Connect vacuum hose to check valve on power brake and tighten hose clamp. Connect brake line fittings to end plate **On Ford and Studebaker,** connect stop light wires. **On all cars,** bleed system (see above).

MIDLAND POWER UNIT

F rd Trucks (1954-60) ℂ
F rd Pass. Cars (1954-57)
F rd "Thund rbird" (1955-57)

ℂ - Hydrovac Power Unit also used on 1956-60 Trucks

►CHANGES & CORRECTIONS

►*1955 500 & 600 SERIES TRUCK BRAKE PEDAL "KICK-BACK" CORRECTION.* An improved design brake booster hydraulic cylinder spring retainer has been released to prevent possibility of brake pedal "kick-back" This retainer has same number as earlier type (TEAA-2423-A) but is identified by code number (8-55) to right of word "retainer" on package

DESCRIPTION: Consists of a vacuum power chamber, hydraulically actuated vacuum control valve, and an hydraulic slave cylinder, all in a single sealed unit Unit is mounted on left side of engine compartment and connected in hydraulic brake line between master cylinder and wheel cylinders There is no mechanical connection and no adjustments are required

OPERATION: With engine running, brakes released, power diaphragm is vacuum suspended Depressing pedal causes fluid to pass from master to slave cylinder moving control valve piston, which admits atmospheric pressure to front of diaphragm As pushrod moves, check valve seals fluid in slave cylinder and hydraulic line pressure builds up to operate brakes

REMOVAL & INSTALLATION: Depress pedal a few times to relieve vacuum Remove lines and attaching bolts To install reverse removal procedure

TROUBLE SHOOTING Brake Pedal Kicks Back—Engine Running—Slave piston cups leaking hydraulic check valve leak intermittent vacuum leak in unit

Brakes Do Not Release—Engine Running: Control valve piston sticking, hydraulic (slave piston) sticking, broken or weak control valve spring, dented or leaky diaphragm body

Vacuum L ak With Brak s Released—Engin Idl s Normally: Defective "O" ring seal or body-to-slave cylinder gasket, dirt or worn atmospheric valve seal, defective or dirty vacuum check valve

Vacuum Leak With Brakes R l ased—Rough Engin Idl: Leaking diaphragm in vacuum chamber, leaking control valve piston or diaphragm, leaking control valve vacuum valve seal.

Hard Pedal—Indicating Inoperative or Weak Booster: Clogged air cleaner element, sticking hydraulic (slave) cylinder piston, air leak at atmospheric valve seal, control valve diaphragm, control valve piston, or power chamber diaphragm

OVERHAUL: *TRUCK NOTE*—Do not remove breather in cab or controls mounted in engine compartment unless operating conditions indicate repairs are necessary

Disassembly: 1) Remove control valve bypass tube from control valve and the body Remove stop light switch Mark both halves of body with a scriber, then mark flanges of control valve and slave cylinder so parts can be assembled in their original positions

2) Remove clamp then remove outer body and the diaphragm and pressure plate assembly with return spring Remove vacuum check valve from inner body

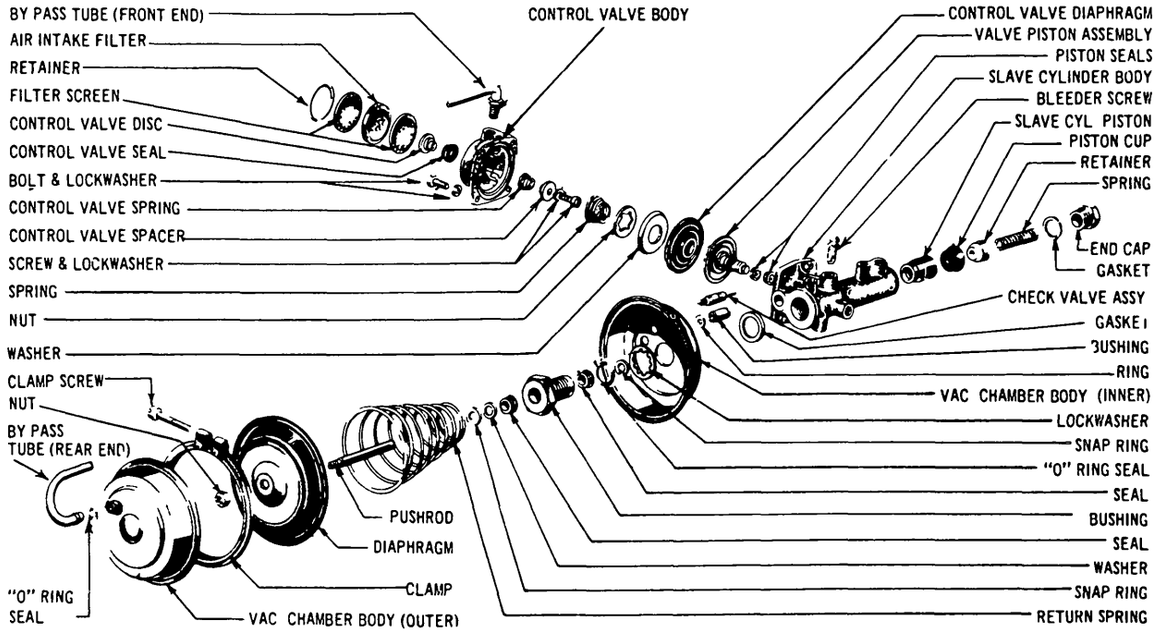
3) Remove retainer and air intake hose fitting (or snap

CONTINUED ON NEXT PAGE

MIDLAND POWER UNIT (C ntinu d)

ring, screens, and filter) from control valve body Remove control valve to slave cylinder attaching bolts and lockwashers. Lift the control valve body, diaphragm spring, and the control valve piston and diaphragm assembly from slave cylinder body

4) Remove pushrod bushing, lockwasher, inner body, and gasket from slave cylinder body Remove transfer bushing and "O" ring seal from cylinder body



5) Remove end plug or cap, gasket, return spring and retainer, from end of slave cylinder. Remove slave cylinder piston cup and piston from cylinder. Remove inner and outer pushrod bushing seals.

6) Remove inner and outer seals from control valve piston. Remove control valve diaphragm plate and retaining nut by prying inner tangs of nut away from piston shaft. Separate the control valve disc and spacer by removing attaching screw and lockwasher. Then remove disc, seal, spring, and spacer from control valve body. Remove check valve retainer, check valve and return spring as an assembly from slave cylinder piston. Remove pushrod from diaphragm and disassemble check valve.

Insp ction: Wash all metal parts in brake fluid and dry thoroughly Use air to dry all internal passages. Replace all worn or damaged parts and if slave cylinder bores or control valve plunger show wear or evidence of corrosion, the slave cylinder body should be replaced. Replace pushrod if rough or damaged. If control valve seat is worn or damaged, replace control valve body.

R assembly: **1)** Assemble diaphragm on pushrod After nut is tightened, coat threads with shellac to prevent leakage. Assemble control valve disc, seal, spring, and spacer in the control valve body with screw and lockwasher. Position control valve diaphragm and plate on control valve, and secure diaphragm and plate solidly in place with nut Install control valve piston seals on piston

2) Insert check valve spring and valve and retainer in slave cylinder piston. Be sure check valve floats freely and does not bind in bore. Install the inner and outer pushrod bushing seals, and secure them in place with the retainers

TYPICAL MIDLAND BRAKE POWER UNIT

3) Coat the piston bores in slave cylinder body with hydraulic fluid. Dip slave cylinder piston, seal, retainer, and spring in fluid. Install piston in bore with recessed end toward pushrod bushing end of body Carefully position seal and retainer on top of piston. Insert spring in retainer, and secure it in place with end plug or cap, using new gasket.

4) Place new gasket and inner body of vacuum power chamber on slave cylinder body Make certain transfer bushing and "O" ring are in place before inner body is installed on cylinder body. Install pushrod bushing lockwasher over end of bushing. Thread bushing in place, be sure inner body seats squarely on cylinder body, then tighten bushing securely.

5) Dip control valve piston in hydraulic fluid, then install control valve. Position control valve spring on control valve diaphragm with small end of spring on diaphragm plate. Position control valve body over spring, align the scribe marks, then install control valve body-to-slave cylinder body attaching bolts and lockwashers. Tighten bolts solidly. Install air intake hose fitting (or screens, filter, and snap ring) on control valve body.

6) Place small end of diaphragm return spring on top of pushrod bushing Carefully insert end of pushrod into bushing. Align diaphragm plate on large end of spring. Place outer body of vacuum power chamber on top of diaphragm with marks in alignment Install clamp, making certain diaphragm head is properly positioned between two halves of chamber, then tighten clamp screw firmly.

7) Assemble check valve, then install it in inner body of chamber. Install a new seal on slip end of bypass tube, then install tube in outer body of chamber and control valve Tighten nut on control valve body firmly.

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 BUICK CHECK VALVE NOISE CORRECTION (Caused by Vacuum Leak Between Check Valve & Vacuum Tank or in Check Valve) (NOTE*–Check valve chatter may be caused by riding brake pedal causing drain on vacuum supply). Make vacuum check, after making sure that brake pedal is in fully released position, properly adjusted and with no binds in it, and that the check valve is free of foreign material and operates freely. If vacuum assist still not obtained, replace check valve (NEW Part No. 5455046) as follows: Remove vacuum line from check valve to "T" connection. Remove cap from old valve body and remove spring and valve *(NOTE*–Leave valve body attached to frame). Discard valve and spring. Cut vacuum pipe just ahead of first bend (From "T" connection end). Install 3/8" pipe flare nut, flare pipe. Install new valve on end of pipe that was just cut off and flared. Replace old valve cap (without spring and valve) Install new valve and vacuum line as an assembly and make sure hose at "T" connection makes sufficient contact with new valve Recheck vacuum assist

►*1955 BUICK HYDRAULIC PISTON REACTION PLATE INSTALLATION CAUTION* If reaction plate installed backwards, faulty brake operation will result and it will be difficult to select proper number of shims (See Overhaul below). Reaction plate should have concave side of rim toward shoulder of piston and rounded side of rim against reaction levers.

►*1955 PONTIAC MASTER CYLINDER SECONDARY CUP EXPANDER ASSEMBLY PRODUCTION CHANGE.* New finger type expander and spacer assembly, Part No 5454862, now used in production, and replaces spring loaded expander used on early cars. Finger type expander requires a new spacer (identified by black oxide finish). *NOTE*–It is not necessary to add expander to early production units which did not originally have it.

►*1955-56 BUICK SLOW PEDAL RETURN OR FAILS TO RETURN TO NORMAL POSITION·* This is caused by vacuum leaks in power brake cylinder, that are the result of any one of three conditions that follow

1) Brok n Air Valv . To check for broken air valve, push in on pushrod to separate valve and piston assembly from power piston, and gently move end of air valve (covered with rubber boot), sideways. Excessive movement indicates broken valve. *CAUTION* - Excessive pressure sideways will break a good valve.

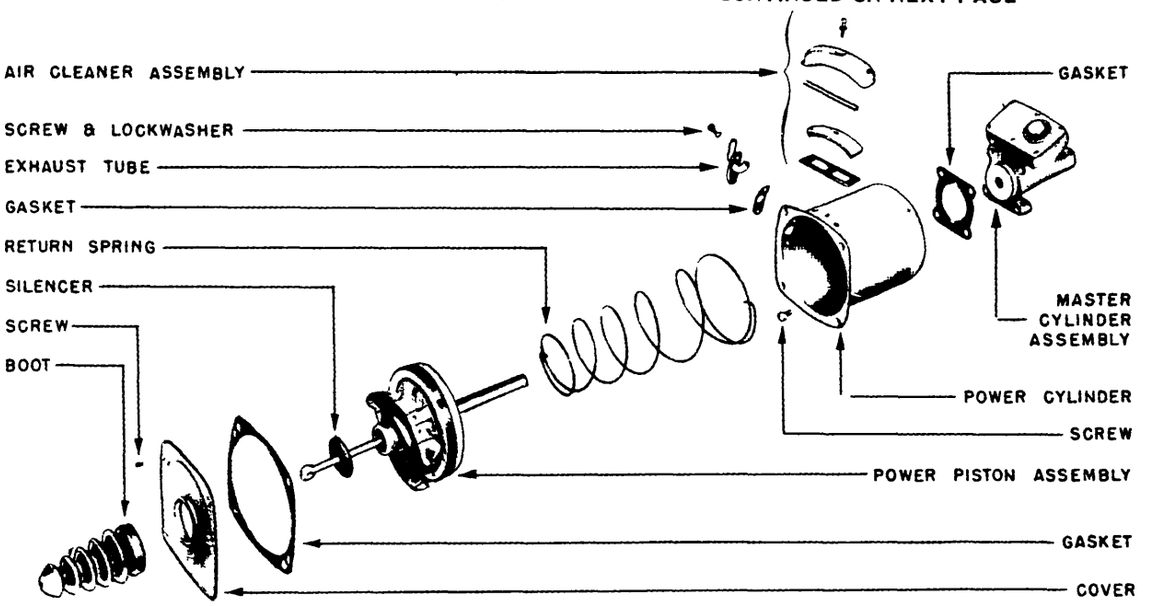
2) Punctured Vacuum H se. Replace with new hose.

3) Weak Inner Piston R turn Spring. Valve & Piston assembly (small piston) not returning to unapplied position completely, causing vacuum leaks between valve reaction plate to piston seal and power piston (large piston). To correct install new inner piston return spring Buick No. 5455800. *NOTE* - New spring has greater length with larger coil diameter than first type spring. To install, remove power brake cylinder from car, mount it in vise (do not crack cylinder by overtightening vise), with hydraulic cylinder down. Remove pushrod boot and retainer from cover, air cleaner assembly, two housing cover screws, cover and gasket. Hold power piston down, disconnect vacuum hose from tee, remove tee and gasket from housing. Slowly release power piston. *NOTE* - Make sure lip of leather piston does not catch in holes in housing. Remove center return spring (valve and piston return spring) and replace it with new spring No. 5455800. Center new piston return spring in cylinder housing, then large return spring around it with its smaller end down. Locate bent end of spring wire between one of bolt heads and adjacent dimple in housing. Place power piston with attaching parts on large return spring so bent end of spring wire rests between two round bosses on piston guide. Locate piston so side of boss opposite vacuum hose clears vacuum tee hole in housing by ¾". Push power piston down in cylinder entering hydraulic piston in hydraulic cylinder and hold piston down while installing vacuum tee with gasket and two screws. Push vacuum hose on tee 5/8". Push power piston down to check for free operation and proper location of springs, then install gasket and cover on cylinder housing with two screws. Install filter assembly and rubber boot, and install power unit on car.

►*1956 CADILLAC BRAKE PEDAL LINKAGE BIND CAUSING BRAKE DRAG* Binding can exist at brake rod to relay connection, pedal rod at toe-board hole, and pedal rod-to-felt air seal retainer. *NOTE* - Check level of pedal for correct horizontal position in car as viewed from seat, before making repairs to eliminate rod binding. Correct by shimming between attaching bracket and steering column support

Pedal Rod to Toe-board Hole - Secure 1/8" clearance on rod with pedal in applied position, by moving pedal attaching bracket at support mount, laterally or by enlarging hole in toe-board.

Pedal Rod at Felt Air Seal - Centralize seal around rod by removing one screw from retainer and rotating entire seal and retainer around other screw, and relocating first screw.



Brake Rod to Relay Connection - With brakes fully released, clevis pin should fit easily into clevis pin hole. Remove stock on upper edge of lower relay arm until clevis pin will enter freely

►*1957 BUICK BRAKE PEDAL HEIGHT ADJUSTMENT* With brake pedal in the full "OFF" position, distance from floor mat (with mat depressed) to top of rubber pad on brake pedal should be 5½". If not correct, loosen pushrod locknut and rotate pushrod as necessary for correct adjustment.

►*CADILLAC OIL DISTRIBUTOR BAFFLE INSTALLATION CAUTION·* **Oil distributor baffle now located against end of cylinder and held in place by piston return spring. DO NOT discard baffle Install baffle with small pocket in line with lubrication hole and large pocket in line with indentation near master cylinder attaching screw hole**

DESCRIPTION: Self-contained, combined vacuum and hydraulic unit using intake manifold vacuum and atmospheric pressure for its pressure. In "brake-released"

CONTINUED ON NEXT PAGE

MORAINE POWER BRAKE ASSEMBLY

MORAINE POWER UNIT "PISTON TYPE" (C nt.)

position power piston is balanced by atmospheric pressure on both sides of piston. Unit incorporates two main sections—vacuum power cylinder and hydraulic master cylinder. Unit replaces conventional master cylinder only. *NOTE*—On Buick master cylinder fluid reservoir is separate.

OPERATION: With engine running, brake unapplied, both sides of power piston are under atmospheric pressure. On application of brake pedal, intake manifold port opens and creates vacuum right side of power piston. Atmospheric pressure then moves power piston to right thereby exerting thrust on hydraulic plunger. This increases line pressure to four wheels. Release of brake pedal restores atmospheric pressure balance in power cylinder. In case of engine failure and consequent loss of engine vacuum, several applications of brake are possible by using vacuum supply in vacuum reservoir. In case of complete vacuum loss, brakes can be applied in conventional manner, although more effort is required due to loss of power assist

CHECKING & ADJUSTMENT: Check all parts of power brake system before disassembling Power Brake Unit whenever brake trouble experienced.

Adjustments: No special adjustments required. Anytime brake pedal goes to within 1". from floor (floor mat to underside of pedal pad), brakes should be adjusted. At time brakes adjusted, following inspections must be made.

1) Check vacuum lines and connections between intake manifold, check valve, vacuum reserve tank, and vacuum power cylinder for possible vacuum leaks.
2) Check fluid level in master cylinder reservoir
3) Check condition of air cleaner element and insert clean element, if necessary.
4) Check steering column pedal plate for loose screws. Check for free operation of brake pedal If binding exists, check for misalignment between pedal and vacuum cylinder pushrod.
5) Check stop light switch for proper operation

Bl eding Brakes: Bleed in same manner as for standard brakes. Do not use vacuum assist while bleeding. Engine should not be running and vacuum reserve should be reduced to zero by applying brake several times before starting bleeding procedure. *NOTE* - On Cadillac bleed master cylinder first by attaching bleeder hose to bleeder fitting on end of master cylinder and backing off fitting ¾ turn, and bleeding until brake fluid runs clear and free of bubbles Then proceed to each wheel cylinder.

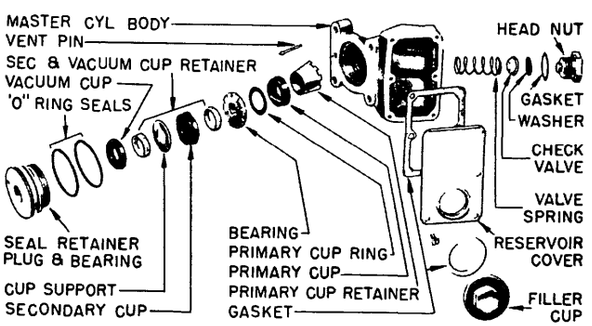
LUBRICATION: Check level of fluid in reservoir every 1000 miles Bring level up to **(Buick)** - 1/4" below lowest point of bottom thread in filler opening, **(Cadillac)** - 3/4" below top, **(Chevrolet)** - 1/2" below top of filler cap **(Oldsmobile)** - Fluid must register on dipstick, **(Pontiac)** - 1" from top of filler plug opening

PERIODIC SERVICE: Intake manifold tee connector should be removed and cleaned Spring and Fall or every 10,000 miles

TROUBLE SHOOTING: Before checking Power Brake Unit for source of trouble check brake system.

Hard P dal 1) Vacuum failure due to faulty vacuum check valve, collapsed vacuum hose, plugged vacuum fittings, hose or pipes, leak between vacuum power cylinder and hydraulic master cylinder
2) Bound up pedal mechanism
3) Power Brake unit trouble—internal vacuum hose loose or restricted, jammed sliding valve, vacuum leaks in unit caused by loose piston plate screws, loose piston packing, faulty master cylinder piston, vacuum seal, or leak between hydraulic master cylinder and vacuum power cylinder, defective diaphragm

Grabbing Brakes (Apparent Off-and-On Condition): Power Brake unit valve trouble—reaction diaphragm leakage, faulty rubber bumper pad in reaction diaphragm, sticking sliding valve reaction, restricted diaphragm passage, master cylinder piston binding in guide



Pedal Goes to Floor (Or Almost to Floor): Brake adjustment, fluid reservoir needs replenishing, power brake hydraulic leakage—defective primary or secondary cup, defective vacuum seal, defective head nut or head nut gasket, cracked master cylinder casting, leaks at wheel cylinders or in pipes, or in connections.

Brakes Fail to Release (Or Slow Release): 1) Bound up brake pedal linkage
2) Weak brake shoe return springs.
3) Faulty residual check valve, excessive hydraulic plunger seal friction, excessive piston packing friction, restricted air passage in vacuum piston, restricted air cleaner, sticky air valve, broken piston return spring, broken air valve return spring

REMOVAL & INSTALLATION: *See Individual Car Pages*

OVERHAUL: *CAUTION – Clean unit externally with declene or diacetone alcohol DO NOT USE ANTI-FREEZE ALCOHOL, KEROSENE OR ANY OTHER OTHER MINERAL OIL CLEANING FLUID Hands must be free of mineral oil or grease when handling power brake parts* Remove filler cap and pump the pushrod to remove all brake fluid Then proceed as follows

Vacuum Cylinder Removal - *CAUTION - Air cleaner must be removed first to prevent air cleaner retainer screw from damaging leather packing of piston* Remove boot and felt washer from pushrod, and vacuum cylinder end plate and gasket Remove rubber hose from vacuum inlet tube inside power cylinder Hold vacuum piston assembly back in power cylinder and remove vacuum tube screws from cylinder. Remove tube Remove vacuum piston assembly and spring then scribe a mark across power cylinder and master cylinder for reinstallation and remove three master cylinder to vacuum cylinder screws Remove master cylinder.

MASTER CYLINDER UNIT

Disassembly: Vacuum Piston - On pushrod side, remove lock ring and stop plate, pull out air valve and pushrod (valve return spring, snubber and valve shims will come out with pushrod) Be sure to note number of shims *NOTE* - It is not necessary to remove pushrod unless it is noisy or excessively loose To remove pushrod, remove snap ring, pull out washer and pushrod from air valve, then remove rubber bumper from end of pushrod and "O" ring from air valve Press down on piston guide and remove screws, then carefully lift off piston guide and hydraulic plunger assembly. Remove "O" ring from vacuum piston guide. Slide vacuum piston guide off hydraulic plunger and remove "O" ring from plunger. If reaction plate or hydraulic piston defective, remove snap ring to separate them Remove six reaction levers, reaction spring, valve reaction plate and floating valve spring. Remove leather cup, cup expander and felt wick Remove floating control valve from vacuum piston To disassemble floating control valve assembly, pry retainer off diaphragm, push floating control valve through diaphragm (this frees retainer plate), then pull diaphragm from retainer Remove rubber vacuum piston top

Hydraulic Cylinder - Clamp hydraulic cylinder in vise with plunger up, then use wrench J-5794 to remove cylinder plug Remove two "O" rings from outside diameter of plug Remove secondary cup, washer, retainer and vacuum seal Lift out expander, spacer, plunger bearing, washer, primary cup and retainer Remove head nut assembly *CAUTION* - Head nut is under spring tension Remove residual check valve and spring, then remove rubber check valve seat washer from head nut

Cleaning & Inspection: Clean all parts with diacetone alcohol or clean brake fluid *CAUTION* - DO NOT use anti-freeze alcohol, kerosene, or any other cleaning fluid that might contain a trace of mineral oil Blow out all passages, orifices and valve holes Air dry and place cleaned parts on clean paper or lint free cloth *NOTE* - Should there be evidence of contamination or corrosion, completely flush hydraulic brake system Inspect rubber or leather parts for cuts, nicks, or other damage Discard all used "O" rings and external gaskets Check all friction surfaces for scratches, scores, pits, or cracks that might affect sealing or sliding action of piston cups Look for damaged threads or gasket seats, distortion or damage to rubber parts. Check master cylinder for free sliding fit with slight play Check vacuum cylinder for scratches, pits or other damage

Reassembly· Hydraulic Cylind r - Place cylinder in vise with threaded outlet hole up and insert check valve spring, then place check valve (concave side up) on spring Place new gasket and stretch new seat washer into head nut Screw head nut in place and tighten to 80-90 ft lbs Install filler cap and gasket Clampmaster cylinder in vise with large counterbore up Coat counter-

CONTINUED ON NEXT PAGE

MORAINE POWER UNIT "PISTON TYPE" (C nt.)

bores and threads with brake fluid, place conical primary cup retainer (notched end down) into bore, press primary cup into bore (lip facing and centered over small end of conical retainer) Place steel primary cup washer in place on back of primary cup, add plunger bearing (notched side up) so hub of bearing fits into counterbore on back of primary cup Place spacer on top of bearing, and new expander on top of spacer (fingers down) Make sure spacer and expander are centered over plunger bearing Place two new "O" rings on outside grooves of cylinder plug *CAUTION - DO NOT place "O" ring in center groove that has four vent holes* Install secondary cup washer and seat secondary cup (ribbed side up) in cylinder plug Lubricate "O" rings, secondary cup, and leather seal with shock absorber fluid, then carefully install cylinder plug and tighten to 20-30 ft lbs Place vacuum cylinder gasket on hydraulic cylinder so vent passage is open, (use alignment marks), attach vacuum cylinder to master cylinder and torque screws to 12 ft lbs

Vacuum Piston - Assemble floating valve with flat side of retainer ring against diaphragm, fit lip of diaphragm over outside diameter of retaining ring Hold flat side of diaphragm retainer plate against diaphragm and press floating valve into place in diaphragm Press valve spring retainer over hub of floating valve and the inner lip of the diaphragm Push floating valve assembly into vacuum piston, then install felt wick in expander and expander assembly in groove in vacuum piston with expander fingers outward and toward hub *NOTE* - Saturate new wick with Automatic Transmission fluid Hold wick and expander in place and install leather packing or cup (use cylindrical container to confine packing during installation) Snap valve diaphragm spring in place over valve spring retainer, seat valve plate on top of valve diaphragm spring so center portion nests in spring Seat reaction spring in recess of valve diaphragm retainer ring Set six reaction levers in place so small ends are toward center and they rest on reaction spring Install "O" ring in hydraulic plunger groove, add plunger reaction plate with raised edge extending away from plunger and install snap ring Install "O" ring onto machined hub of vacuum piston guide, lubricate plunger "O" ring and adjacent surface with silicone grease and assemble vacuum piston and piston guide Place plunger and reaction plate on reaction levers, press down levers until they are flat and each lever properly seated, then slide piston guide down plunger and into position on vacuum piston Align raised holes in piston guide with threaded holes in vacuum piston then install screws and tighten to 5-6 ft lbs *NOTE* - Master cylinder piston should have slight movement in vacuum piston assembly Install new rubber vacuum piston stop washer on hub flange of vacuum piston with rubber cement Assemble rubber bumper on end of pushrod, insert bumper and pushrod assembly into air valve Allow metal washer on pushrod to seat on back of rubber pushrod bumper and install snap ring Be sure pushrod is firmly locked in air valve Place new "O" ring in narrow groove on outside of air valve, coat ring and outside diameter of air valve with silicone grease Place same number (or four new) shims on Tool J-5805, invert vacuum piston and insert gauge into bore of vacuum piston Turn vacuum piston over and check position of pin Remove or add shims until pin is flush with or just slightly above gauge body When pin is more than .010" above gauge body, disassemble and check for bent reaction levers, reaction plate, or valve plate Place correct shims and snubber on small diameter of air valve, then insert valve return spring into small bore of air valve Hold vacuum piston assembly with hydraulic cylinder upward, insert (from below), the air valve, spring, and pushrod assembly into hub of vacuum piston Hold pushrod with air valve in vacuum assembly and turn assembly over and install stop washer and triangular lock ring (use small screwdriver as a pry bar to install lock ring) *NOTE* - Air valve will have approximately 1/32" travel against valve return spring before picking up load

Vacuum Piston Installation - Lubricate vacuum cylinder bore with Automatic Transmission or Hydraulic Brake fluid and place vacuum and hydraulic cylinder assembly in vise with vacuum cylinder upward Insert large coil return spring in vacuum cylinder with large diameter of spring at bottom (hook on bottom of coil spring should be placed in narrow space between any one of hex head bolts and closest locating dimple) *NOTE - See "Cadillac Oil Distributor Installation Note" above* Coat vacuum piston leather packing or cup with Automatic Transmission or Hydraulic Brake fluid, then install vacuum hose to vacuum piston assembly with rubber cement and position vacuum piston assembly on top of coil spring Press down on vacuum piston assembly and install vacuum inlet tube and gasket (slip hose onto inlet tube approximately 5/8") Release vacuum piston against inlet tube, with hose flat against piston without rubbing on vacuum cylinder walls Install vacuum cylinder end plate and gasket Install filter element and air cleaner cover by inserting filter cover attaching screw in cover and assembling filter element over cover screw Then install assembly to power cylinder

►CHANGES, CAUTIONS, CORRECTIONS

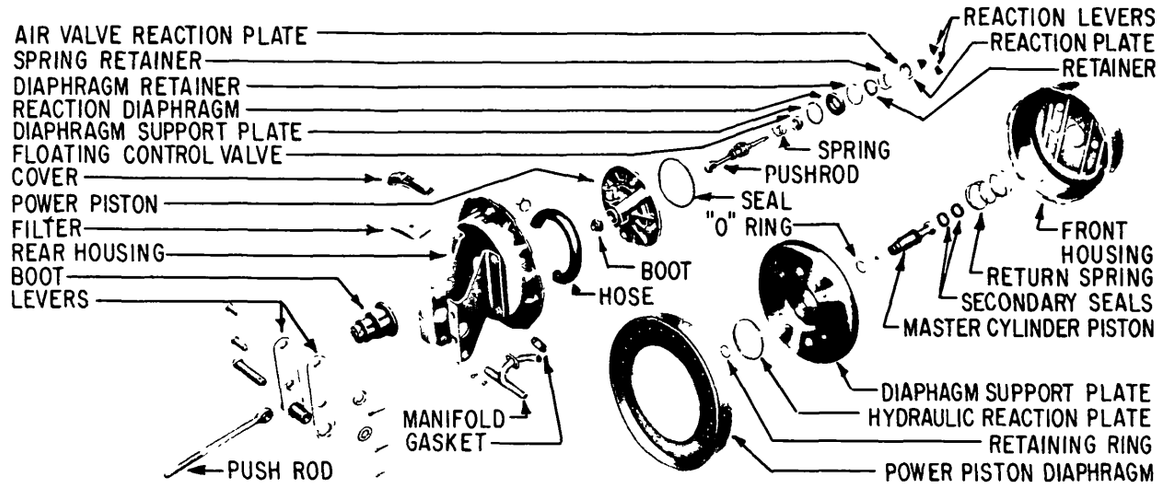
►*1960 CADILLAC POWER BRAKE UNIT AIR VALVE RETURN SPRING PRODUCTION CHANGE.* A new spring, Part No 5460228, is being used in production and may be used for replacement to improve the "feathering" ability of the unit Brake units after Engine No 085791 will have the new spring

DESCRIPTION: This new diaphragm type vacuum brake unit has the diaphragm assembly balanced in atmospheric pressure (both sides of vacuum diaphragm are open to atmospheric pressure when in the released position) The hydraulic reaction feature of this unit transmits changes in hydraulic pressure to the vacuum valve through a reaction diaphragm to provide a more positive "feel" for the operator The new conventional (piston) type master cylinder is bolted to vacuum unit and can be removed without removing power brake unit from car The 1960 models use selective shims between power cylinder and brake master cylinder On Buick units, an additional reaction disc is used between master cylinder piston reaction plate and reaction levers

OPERATION: As brake pedal is depressed, the operating rod moves air valve forward until its seat contacts floating control valve, sealing off atmospheric pressure Further movement carries floating valve away from seat on power piston and opens the area forward of diaphragm to vacuum source while air valve remains closed As air is exhausted forward of diaphragm, atmospheric pressure on opposite side moves diaphragm and piston assembly forward As diaphragm and piston assembly moves forward, the master cylinder piston is depressed into master cylinder As pressure builds up in master cylinder, the hydraulic piston reaction plate moves away from its stop and presses against the reaction levers These levers in turn swing around their pivots and push the valve reaction plate back against the floating control valve snubbers In this manner, approximately 40% of the load on master cylinder piston is transferred through air valve and operating rod to the brake pedal

REMOVAL: Power Brake & Master Cylinder - Disconnect hydraulic line from master cylinder and vacuum line from power unit, then disconnect pushrod from brake pedal Remove nuts attaching power unit to firewall and remove unit

Master Cylinder: *NOTE - Master cylinder can be removed from power unit without removing power unit from car.* Remove hydraulic connection from master cylinder (cover opening and pipe to prevent dirt entering) Remove master cylinder attaching nuts and remove master cylinder from vacuum unit *NOTE - Master cylinder piston assembly will r main attached to vacuum unit. If necessary to replac piston, it will b nec ssary to disassemble vacuum unit.*



CONTINUED ON NEXT PAGE

MORAINE "HYDRAULIC (DIAPHRAGM) REACTION" TYPE (Cont.)

►*DISASSEMBLY & OVERHAUL CAUTION:* Use care to prevent damage to parts. Do not allow oil or grease to come in contact with diaphragm or other rubber parts. If necessary to remove power cylinder from master cylinder (1960 models), be careful not to damage selective shims found between these two parts. If shims are damaged, replace with new shims of the same thickness, as these shims control the distance master cylinder piston projects from front housing.

DISASSEMBLY: Power Brake Unit - Place power brake unit in a vise, clamping sides of master cylinder with pushrod up, then disconnect linkage from air valve pushrod. On Chevrolet and Pontiac, insert a pipe through rear housing mounting bracket holes and rotate counterclockwise to unlock rear housing from front housing. On Cadillac, use two bars between mounting studs (cover studs with heater hose or other suitable material to protect threads) for leverage to rotate housing. Lubricate end of air valve pushrod with brake fluid and lift rear housing so boot is free from end of pushrod, then pull vacuum hose from fitting on inside of rear half housing. *NOTE - Hose is fastened to power piston with a hose clamp.* Remove power piston assembly by lifting straight up, then remove power piston return spring. Reposition master cylinder in vise and remove master cylinder attaching nuts, then remove front half housing from master cylinder. Remove air filter cover and element from rear half housing. *NOTE - Do not disassemble linkage or remove exhaust manifold unless it is necessary to replace parts or to lubricate pins.*

Power Piston: Mount power piston in a vise so assembly is held lightly by two of the four retaining screw bosses and so master cylinder piston is upward. Remove screws and lockwashers from power piston assembly and lift large diaphragm and support plate from piston assembly. *NOTE - The support plate is under spring tension.* Remove power piston seal ring, then remove three reaction levers, air valve reaction plate, floating control valve return spring, and combination reaction and air valve return spring. Remove power piston from vise. Remove air valve boot from groove in power piston, then pull boot over end of rod. The air valve and pushrod assembly can now be pushed through the power piston dislodging floating control valve and reaction diaphragm assemby by pushing on end of pushrod assembly. *NOTE - Floating control valve assembly can also be removed without removing air valve by prying up under one side of reaction diaphragm retainer with a thin blade screwdriver.* Do not disassemble floating control valve further unless it is necessary to replace worn or damaged parts. Remove large power piston diaphragm from support plate and inspect for cuts, pin holes, distortion, folds, or cracks. Remove reaction plate retaining ring from master cylinder piston with snap-ring pliers, then remove reaction plate from piston and press piston through large diaphragm support plate. Remove master cylinder piston "O" ring. *NOTE - Do not remove secondary seals from master cylinder piston unless it is necessary to replace parts. To remove secondary seals, use a thin blade screwdriver to lift seal out of groove and over end of piston.*

MORAINE BRAKE POWER UNIT ASSEMBLY

CLEANING & INSPECTION: Wash all parts in alcohol and blow dry with air. Blow dust and cleaning fluid out of all internal passages. If inside of front housing is slightly scored or scratched, clean with crocus cloth or fine emery cloth. If scratches in front housing cannot be removed, replace housing. Keep all parts clean and do not allow them to come in contact with oil or grease.

REASSEMBLY: Power Piston - Mount piston in a vise with hub end down and lightly hold piston by two of the four screw bosses. Insert air valve and pushrod assembly into power piston with "eye" end of pushrod down. Place reaction diaphragm support plate (curved side down) into center cavity of power piston. Lubricate floating control valve with silicone grease and install into reaction diaphragm. Insert reaction diaphragm retainer under lip of reaction diaphragm and place the floating control valve spring retainer over reaction diaphragm so that the six rubber bumpers are properly positioned in spring retainer. Wipe a film of silicone grease on outside diameter of reaction diaphragm, then place floating control valve and reaction diaphragm assembly over air valve portion of air valve and pushrod assembly so that rubber face of control valve rests on annular seat of power piston. Press outer edge of reaction diaphragm into position in power piston. *NOTE - Be sure diaphragm is not distorted as the assembly is placed in power piston.* Assemble combination reaction and air valve return spring over air valve and into floating valve spring retainer to seat on the air valve. Install floating control valve return spring over air valve to seat on flange of floating control valve spring retainer. Lubricate 9/16" shaft of air valve with silicone grease, then position air valve reaction plate over air valve with dished side down. Lubricate reaction levers with silicone grease and install levers in machined locations in power piston. Rest small ends of levers on air valve reaction plate. Insert power piston seal ring into inner groove on flat surface of power piston face. If secondary seals on master cylinder piston were removed, reinstall them so lips of seals face small holes in piston. Install "O" ring on master cylinder piston and lubricate it with silicone grease "A", then press piston into large diaphragm support plate from flange side. Position reaction plate (with raised rim away from large diaphragm support plate) over master cylinder piston and secure with reaction plate retaining ring. Pull skirt of large diaphragm over support plate, then pilot master cylinder piston and diaphragm support plate (with large diaphragm installed over end of air valve) onto the reaction levers, aligning a vacuum port in support plate with passage in power piston. *NOTE - The position of the bead on large diaphragm and reaction l vers must be correct as support plate is finally positioned. If large diaphragm support plate can b hand pressed with relative ease to its seated position, then diaphragm and reaction levers are correctly position d.* Install support plate-to-power piston bolts and tighten to 5-7 ft. lbs. Install air valve boot, then slip exhaust hose on boss so it is parallel to power piston and attach clamp so one ear is against power piston.

Gauging Master Cylinder Pist n: *NOTE - It is n c ssary to gauge piston if front or r ar housing, pow r pist n assembly, master cylinder pist n, or master cylinder assembly is replaced with a new part.* To check master cylinder piston, remove front housing from master cylinder (DO NOT remove selective shims from studs).

CONTINUED ON NEXT PAGE

MORAINE "HYDRAULIC (DIAPHRAGM) REACTION" TYPE (C nt.)

CAUTION - B sur parts are not displaced from bore of mast r cylind r. Place Gauge J-8531 so that it stands perpendicular to front housing next to two lower studs, and bridges over end of master cylinder piston. Piston should be flush with gauge plus or minus .010". If there is excess clearance under legs of gauge, add shims (gasket material) over front housing studs as required to take up clearance. If there is excessive clearance at center of gauge, remove shims. When all shims are removed, and piston end is still lower than gauge, check for deformed parts and replace as required. Install front housing on master cylinder and tighten nuts to 20 ft. lbs. *NOTE - The dimension of Gaug J-8531 provid s a measurement of 1.833-1.844" from nd f mast r cylinder piston to master cylinder surface n pow r cylinder.* If more than five .010" shims are required for correct adjustment, recheck assembly of vacuum piston.

Pow r Brak Unit: Install master cylinder on front housing and tighten nuts to 15-20 ft. lbs., then install this assembly in a vise with open end of front housing up. Install power piston return spring over flange in center of front housing, then position power piston assembly so unattached end of vacuum hose is approximately 180° from master cylinder filler cap. Guide master cylinder piston through return spring and into master cylinder bore making sure the piston contacts back of primary cup. Attach hose to manifold so at least 5/8" of hose is on manifold. Lubricate end of pushrod with brake fluid and force pushrod through boot on rear housing. Install air filter assembly on rear housing. Install large diaphragm in front housing as follows: Start rolling diaphragm into housing, then rest rear housing on front housing. *NOTE - When positioned on diaphragm, air cleaner on rear housing should be slightly to left of master cylinder filler cap.* Plug one side of manifold and apply a vacuum to the other side. Push down on pushrod to permit area under diaphragm to be evacuated and allow atmospheric pressure to force diaphragm into place. Press rear housing down aligning the locking lugs. *NOTE - If diaphragm fails to enter front housing properly, rotate rear housing slightly back and forth while guiding housing into alignment with lugs., If necessary, bend leading edge of rear housing locking lugs to permit engagement.* Rotate rear housing in same manner used for removal, to secure housing to front housing. When properly positioned, air cleaner should be in line with master cylinder filler cap. *CAUTION - Bead of diaphragm must be in recess of front housing and it must not be pinched into slots as the housings are locked together.* Install linkage and check operation of power brake unit.

INSTALLATION: Reverse removal procedure (see above).

BUICK POWER UNIT

Buick (1954)

►CHANGES & CORRECTIONS

►*AIR-VACUUM CYLINDER PRODUCTION CHANGE: Two types used, Series No. 2, identified by letter "K" in front of production date on head of unit, has no control or dampener springs on ends of reaction rod and stop and uses new type power piston and push rod. When overhauling Series No. 1 Power Brake Unit control and dampener springs must be discarded and new power piston and push rod installed. When changes made stamp or paint (use red or yellow) letter "K" on head of unit preceding date of manufacture.*

DESCRIPTION: Vacuum suspended type. Self contained hydraulic vacuum power braking device utilizing engine intake manifold vacuum and atmospheric pressure for its power. It consists of three separate units as follows:

Power Unit: Three elements are combined to make up this single unit, namely

(1) **Air-Vacuum Cylinder** comprising a cylinder, power piston, and piston return spring.

(2) **Hydraulic Cylinder** containing an hydraulic plunger, return spring, and compensating port.

(3) **Control Valve,** mechanically actuated which controls degree of brake application or release in accordance with foot pressure applied to brake pedal It consists of a valve push rod, slide valve, reaction rod, reaction spring assembly, and counter-acting spring.

Hydraulic Fluid Reservoir: Mounted under hood.

Manifold Check Valve: Located in vacuum source line. Maintains vacuum in unit should engine stall.

Pow r Brake Vacuum Pump: Consists of a motor driven vacuum pump with a control relay (see Wiring Diagram). Control relay circuit is connected to accessory terminal of ignition switch (at the car fuse block) and is grounded through the generator main brush. The vacuum pump will operate whenever the engine speed is less than 250 RPM. with the ignition turned on, and supplies vacuum for the power brake operation. When the engine speed exceeds 250 RPM. (which is less than normal idle speed of 450 RPM.) the voltage developed by the generator causes the relay to open and cuts out the vacuum pump. At higher speeds manifold vacuum is sufficient to provide for brake power unit operation. The vacuum pump provides a "Stand-by" vacuum source in the event of engine stalling.

OPERATION: With engine running, brakes unapplied, full vacuum chamber of the unit (both sides of power piston) is held at engine manifold vacuum. Application of the brake pedal causes atmospheric port to open, admitting air to the cover side of the power piston, while full manifold vacuum is maintained on the cylinder side of piston. This pressure differential causes power piston to move forward, thereby exerting a thrust on the small piston in the hydraulic cylinder. This increases line pressure to the four wheels. Release of the brake pedal restores the vacuum balance in the power cylinder. Should failure in the vacuum power system occur, brakes can still be applied conventionally.

POWER BRAKE VACUUM PUMP: Used on all cars after Oct. 1, 1953. May be installed on earlier cars.

Servicing—No attention required other than pump lubrication. At 5000 mile intervals, remove filler screw from top of pump unit, fill as necessary with regular SAE 5 oil.

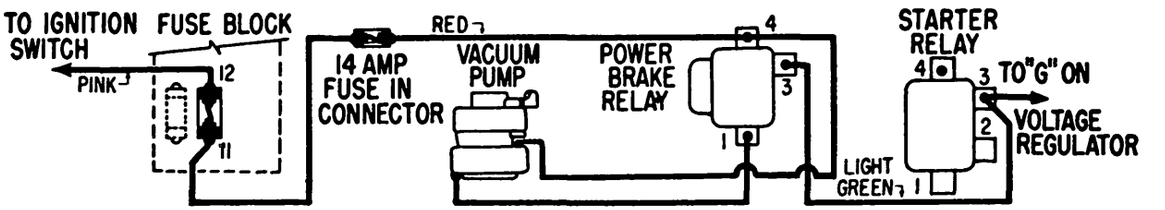
Specifications—Vacuum pump and motor assembly is Trico or Movac. Serviced as an assembly.

Control Relay—Delco-Remy No. 1116896. Contact gap should be .025" (.017-.033").

Contact Opening Voltage—5.7-7.2 volts.

Contact Closing Voltage—Not more than 3 volts after excitation of 12-15 volts.

Fuse—14 ampere. In fuse holder in line between the car fuse block and the control relay.



CHECKING & ADJUSTMENT: Check all parts of the power brake system before disassembling the Power Brake Unit whenever trouble is experienced.

Pedal Linkage Adjustment: In cases where hard or sticky initial pedal pressure is encountered or where pedal fails to return to release position when foot removed, check for lack of lubrication of pedal shaft or binding of clevis pin due to rusting or chloride corrosion. To correct latter condition drive out pin and install new pin or clean up old pin. (Early production has no grease fitting at this point —late production has straight fitting). If no fitting in lever, remove engine splash pan, drill and tap lower end of lever with 1/4 x 28 thread and install a 90° grease fitting. Grease fitting should be turned toward rear of car to permit access to fitting with grease gun. Reinstall splash pin. If binding still occurs with joints lubricated, it may be caused by mis-alignment of pedal shaft with push rod. With push rod in position loosen bolts which attach pedal shaft bracket to frame and permit bracket to shift to a free position. Retighten bolts.

Pedal Stop Adjustment: With pushrod removed, adjust pedal stop bolt so that pedal grommet is compressed to 7/8" height (1954). Tighten locknut.

Push Rod Adjustment: After adjusting pedal stop, install push rod and loosen adjusting jam nut. Holding pedal against stop, adjust push rod length to provide 1/16" clearance or lost motion in power cylinder. Note that in making adjustment only finger tip pressure should be used in pushing rod into power cylinder. Pressures above two pounds will

CONTINUED ON NEXT PAGE

BUICK P WER BRAKE VACUUM PUMP WIRING DIAGRAM

BUICK POWER UNIT (C nt.)

start valve moving. The 1/16" clearance should be in addition to any movement of cylinder valve. ***CAUTION—Great care must be taken when installing push rod into valve body. Any pressure on push rod will open valve. An open valve will build up pressure in hydraulic system causing brakes to lock after a few miles of operation.*** Shorter adjustment safer as long as push rod will actuate brake valve even with brake pedal fully released.

Brake Shoe Adjustment & Pedal Height: Brake shoe settings and procedures same as for manual brakes. After brake shoes properly adjusted, pedal will have certain height which cannot be adjusted up or down. Normal pedal height from lower, back edge of pedal to floor mat is approximately 2".

BLEEDING HYDRAULIC SYSTEM: Using pressure bleeder attached to fluid reservoir under hood of car, bleed **first** the cylinder **end** bleeder until fluid runs clear, **second** at cylinder **flange** bleeder, and last at the four wheel bleeders. When fluid runs clear at all points, start car engine, pump brake pedal several times, and rebleed at two bleeder screws on unit. After bleeding completed, check for brake system leaks while applying heavy brake pressure, with car engine running.

TROUBLE SHOOTING: If operation unsatisfactory, check as follows:

Brake System Loses Fluid: Tighten all connections. If fluid loss still occurs, the trouble is probably worn or damaged primary cup, seal, reaction cup, or reaction "0" ring. If evidence of presence of abrasive material, polish out light scores with very fine polishing paper, then thoroughly wash parts before assembly. Use Kit in reassembly. NOTE—If heavy abrasive action has taken place due to severe contamination of brake fluid, install new power piston and sleeve assembly after thoroughly flushing reservoir and wheel cylinder lines.

Brakes do not Release Properly: Brake pedal arm, fulcrum or pushrod clevis may be binding; push rod adjustment too long; inspection screw and gasket loose or missing; excessive friction caused by "dry" leather piston cup in 6" diameter air-vacuum cylinder. To remedy the latter lubricate cup by oiling through inspection hole in head of unit, using only 2 or 3 ozs of special oil furnished in Kit. Then back off shoes and, with engine running, pump pedal several times until leather frees up. CAUTION—***Do not pour this special oil into reservoir. It will contaminate fluid.*** Other causes of above difficulty are plugged compensation holes near end of power piston sleeve, broken residual valve spring or power piston return spring, cylinder mis-alignment, damaged or weakened control spring or dampener spring in Series 1 units, or weak or damaged reaction rod spring in Series 2 units (Series 1 units have date only on head of unit, Series 2 units have date preceded by "K"—See Production Change above); excessively dry "0" ring on outside diameter of air valve seat (Series 2 units only). Use entire Kit when making replacements.

Power Unit does not Boost: To determine if unit operating, stop engine, then depress brake pedal several times to eliminate all vacuum from system. Apply brakes, and while holding foot pressure on pedal, start engine. If unit operating, pedal will move forward when vacuum power is added to pedal pressure. **If above check shows unit not operating** manifold check valve may be stuck in closed position; bent, broken, or obstructed vacuum source line from engine to check valve or check valve to unit; blocked air inlet to air cleaner cover; blocked air passage in guide sleeve under boot; jammed air valve seat in power piston due to foreign material becoming lodged in power piston air valve seat bore cavity. **If above test shows unit is operating** difficulty may be damaged secondary cup, insufficient fluid in system, glazed brake lining, grease or brake fluid on linings, bound up pedal fulcrum or push rod clevis. When replacing parts, use **entire kit.**

REMOVAL: Remove cranking motor splash pan. Disconnect return spring, remove clevis pin at front end, then remove brake pedal pushrod with cylinder pushrod attached. Disconnect breather tube which is clamped to inlet tube on power cylinder air cleaner cover. Disconnect hose and pipe from vacuum chamber (rear) end of power cylinder. Disconnect reservoir-to-hydraulic cylinder pipe, allow reservoir and pipe to drain. Disconnect distributor-to-cylinder pipe and allow to drain. **Discard old fluid** and cover pipe ends with tape to exclude dirt. Remove nuts and lockwashers attaching power cylinder to its support and remove cylinder from car.

INSTALLATION: To install, reverse removal procedure, except for installation of pushrod and splash pan. Adjust brake pedal stop and pushrod, then bleed hydraulic system.

DISASSEMBLY: Major Components.

Thoroughly clean entire exterior of Brake Power Unit, being careful not to allow dirt and solvent to enter unit. ***CAUTION—Use extreme care to prevent hydraulic system parts coming in contact with mineral oil or grease.***

1) Remove push rod boot and discard.

2) Clamp unit in vise with hydraulic cylinder end down. In clamping unit USE NO MORE PRESSURE THAN NECESSARY TO HOLD IN POSITION (to avoid cracking or distorting cylinder).

3) Remove air cleaner cover, lift out cleaner core.

4) Remove three head bolts and lockwashers, then insert screwdriver in slots in flange, twist, then remove head by tapping up evenly on flange, using screwdriver and heel of hand, or light hammer. CAUTION—Removing head releases return spring unless power piston held down during head removal. Remove return spring.

Vacuum Side of Unit: 1) If power piston and guide have been removed with head, set power piston assembly (with head) in holding fixture with power piston end **down** and guide end **up**, lift head off power piston guide. Remove "0" ring and bumper from outside diameter of head, **discard.**

2) Place head in arbor press with inside face **up.** Remove bearing, "0" ring, and guide seal. **Discard** "0" ring and guide seal, but **not** bearing.

3) With power piston assembly still in holding fixture, bend back lip of leather piston cup, remove wick and expander spring, **discarding wick** only.

4) Disassemble power piston and guide assembly by removing three bolts and lock washers, lift guide assembly off power piston. Discard "O" ring.

5) Remove floating control valve assembly from guide assembly, **discard valve but not spring.** Lift **off leather piston cup and discard, lift air valve seat out of power piston and discard.**

6) Lift out control spring (Series 1 only) and reaction rod spring from power piston, lift out reaction rod and stop assembly, lift out dampener spring (Series 1 only). ***Discard Series 1 control and dampener springs*** (See Production Change above). Remove washer from reaction rod and stop assembly, **discard** washer.

7) Insert drift pin into center of power piston, push out reaction rod piston assembly. Using ***extreme care*** to avoid marring piston, remove "0" ring and reaction cup from reaction rod piston, **discard.**

Hydraulic Cylinder: 1) Drain hydraulic cylinder thoroughly ***(do not re-use fluid).***

2) Set housing and cylinder assembly on bench, with cylinder end **up,** remove four hex nuts and lockwashers from cylinder flange, lift cylinder off housing, **discard** cylinder-to-housing "O" ring.

3) Place cylinder in vise with outlet end **d wn** and flange end **up;** ***do not grip tightly.*** Using wrench, remove cylinder plug assembly (turn counterclockwise). Disassemble cylinder plug assembly ***by hand*** by removing primary cup, retainer and seal. **Discard cup and seal but not retainer.**

4) Remove power piston bearing assembly. Be careful to avoid marring inside diameter of bearing. Withdraw bearing carefully. ***CAUTION—Removal of bearing releases residual valve spring, which will fly out unless controlled.***

5) Remove secondary cup retainers and secondary cup. **Discard cup but not retainers,** remove "0" ring and **discard.** Unless damaged, do not remove blue steel secondary cup supporting washer. If necessary to remove, apply compressed air to a filler port on outside diameter of bearing.

6) Lift residual valve spring retainer off hydraulic cylinder, then lift spring and residual check valve assembly out of cylinder. Remove residual check valve assembly from end of spring by prying off with screwdriver, **discard** valve. Remove and discard rubber residual check valve seat (loosen from end of cylinder by prying with a screwdriver).

CLEANING & INSPECTION: Before any part of unit is reassembled, all parts must be thoroughly cleaned, using diacetone alcohol or clean brake fluid. Avoid allowing any dirt or grit to get into unit during assembly.

REASSEMBLY: ***NOTE—The Power Brake Cylinder Overhaul Kit includes all necessary replacement parts for both vacuum and hydraulic elements. Whenever unit disassembled for service, all parts contained in Kit should be replaced, regardless of whether they show wear at the time. BEFORE REASSEMBLY, WET ALL "O" RINGS AND CUPS WITH BRAKE FLUID, EXCEPT PRE-GREASED "O" RINGS AND SEALS SUPPLIED.***

Hydraulic Cylinder: 1) Mount hydraulic cylinder in vise with flanged end up. Install spring, residual check valve with concave side outward, and head nut with new gasket, and check valve seat in hydraulic cylinder. Tighten nut securely.

2) Install secondary cup retainer in cylinder with notched edge inward, then install secondary cup with flat side outward, using care that cup lip is not turned back at any point. Place secondary cup support washer on piston bearing with brake fluid, install bearing with notched face outward, and center of bearing in cylinder bore.

3) Place primary cup spacer on piston bearing with notched edge down and center it on bearing so it will not be damaged when cylinder plug is installed.

4) Install a new seal into cylinder plug with flat side inward, seal retainer with flat side outward,

CONTINUED ON NEXT PAGE

BUICK POWER UNIT (C nt.)

and a new primary cup with flat side inward against retainer. Use finger to force outside lip of both seal and cup down and outward against bore of plug to insure sealing contact. Screw plug into hydraulic cylinder by hand, then tighten it firmly with a wrench **but do not use force.**

5) Place new "O" ring around cylinder plug, then install hydraulic cylinder on housing with head nut on **opposite** side from vacuum tube on housing. Install nuts on all studs **but do not tighten.**

Power Piston Guide Assembly: NOTE—Before reassembling Guide Assembly, inspect inner end of guide sleeve where it seats against air valve seat assembly. ***This must be Smooth and Clean.***

1) Assemble expander spring to power piston guide assembly, with ends bent in. With power piston guide on bench, shaft end up, by hand place spring in groove so that approximate center of spring coincides with one of the four slots in power piston guide flange; insert wedge (supplied in Kit) through slot to hold spring in place. Next, wrap each end of spring around power piston guide, secure with wedges in two side slots, then complete wrap of spring, with ends overlapping under fourth slot, lock in place with fourth wedge. Remove first three wedges ***(CAUTION—Final wedge will be removed in step 5—wedges must be removed at final assembly).***

2) Saturate wick in special oil supplied with Kit, assemble to power piston guide over expander spring **with grain of felt running parallel to centerline of power piston. Be sure joints of wick and spring do not coincide.**

3) Invert assembly and set in holding fixture, assemble new leather cup to power piston guide, then slide service ring down over leather cup. Be sure heel of leather cup does not ride over edge of power piston guide and flange lies flat against its face.

4) After wetting inside diameter of new floating control valve assembly with brake fluid, place spring on retainer. Press complete assembly down on power piston guide stop. Install new "O" ring on hub.

Head, Bearing & Seal Assembly: 1) With cylinder head resting on bench, hub end up, insert bearing with flat side down, then press new "O" ring into bearing groove with finger. Insert new greased guide seal (felt side up), use care not to remove grease.

2) Using arbor press, apply load to **outside edge** of seal, press into position. Apply only enough pressure to bottom seal on bearing, ***do not crush.***

Power Piston, Guide, Reaction Rod & Head Assembly:

1) Install a new metering hole seal over end of reaction rod in bore of stop and press down firmly. Install a new stop washer over other end of rod and seat it firmly against the stop.

2) Install new "O" ring in groove of reaction rod, being careful to preserve silicone grease on "O" ring, then install reaction rod in piston with a twisting motion.

3) Install a new "O" ring in groove of reaction piston, being careful to preserve silicone grease on "O" ring, then install piston over end of reaction rod **with wide land inward,** and press it down into bore of power piston sleeve.

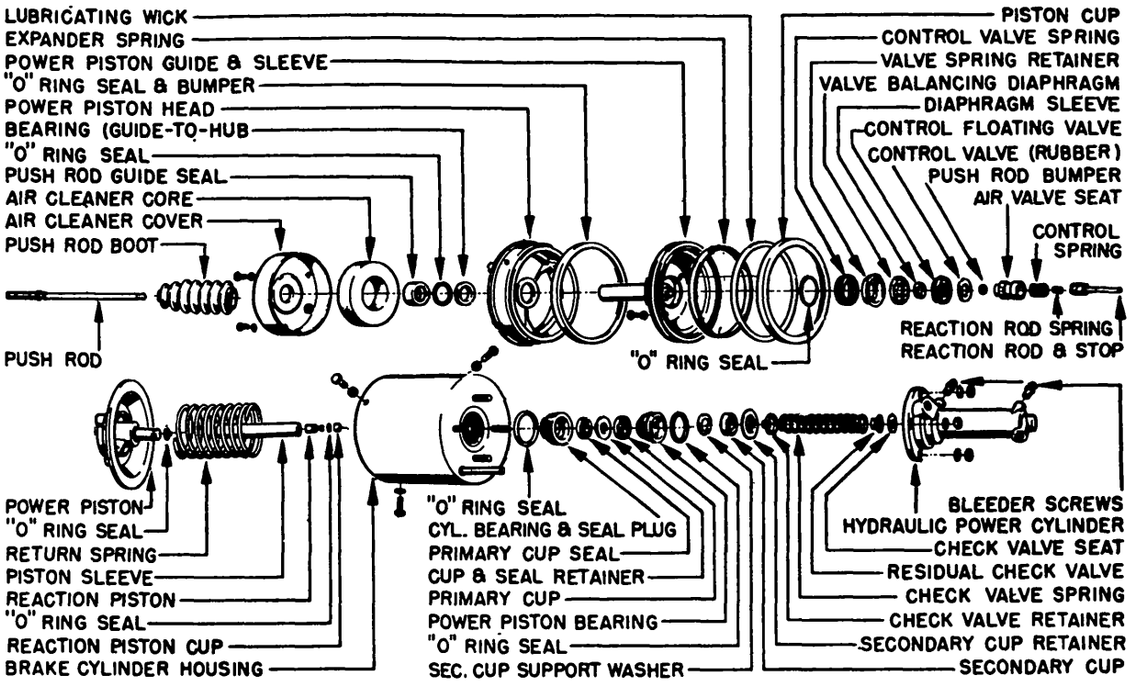
4) Wet a new reaction cup with brake fluid, place it over end of reaction rod with lip side outward and carefully push it down into bore of power piston sleeve. Install spring and retainer over end of reaction rod, compress spring and install a new cotter pin to retain these parts.

5) Mount piston on holding fixture with sleeve down, then install control spring around reaction rod stop.

6) Install new "O" ring in outside groove of air valve seat, being careful to preserve silicone grease on "O" ring, then install valve seat assembly in power piston above reaction rod.

7) Place piston guide over piston and insert push-rod through guide to hold air valve seat down against reaction rod spring while starting bolts with lockwashers. Use three equally spaced holes in guide (Other three holes are air passages). After starting one bolt, remove expander spring wedge, then install other bolts and tighten all securely, using care not to strip threads in aluminum piston. Remove service ring.

8) Place cylinder head on bench, hub end up. Insert new guide seal into hub between bronze bearing and flat wick retainer washer that are inside hub; lips of seal must be upward away from bearing. Slide wick retainer washer down against seal, install a new wick in hub between washer and outer lip of hub, then move washer up snug against wick. Apply any remaining grease in seal and wick packing envelopes to inside of hub.



Complete Unit: 1) Install new rubber "O" ring and bumper on outside diameter of head, then wet outside diameter of rubber with oil supplied in Kit. Oil inside of vacuum cylinder and oil leather cup on outer diameter of power piston guide.

2) With housing and cylinder assembly held in vise, housing up, install return spring so that it nests inside the four cylinder flange head bolts.

3) Set power piston and guide assembly in place with retaining shoulder nesting in return spring, then press power piston and guide assembly down against return spring and into housing about two inches. Pour remaining special oil supplied in Kit (should be 1-2 ozs.) into housing on power piston assembly. ***Avoid pouring oil into air holes.***

4) While holding power piston down, assemble cylinder head assembly over power piston guide sleeve and into housing. Locate head with inspection screw hole on opposite side of unit from vacuum tube on other end of housing (1954).

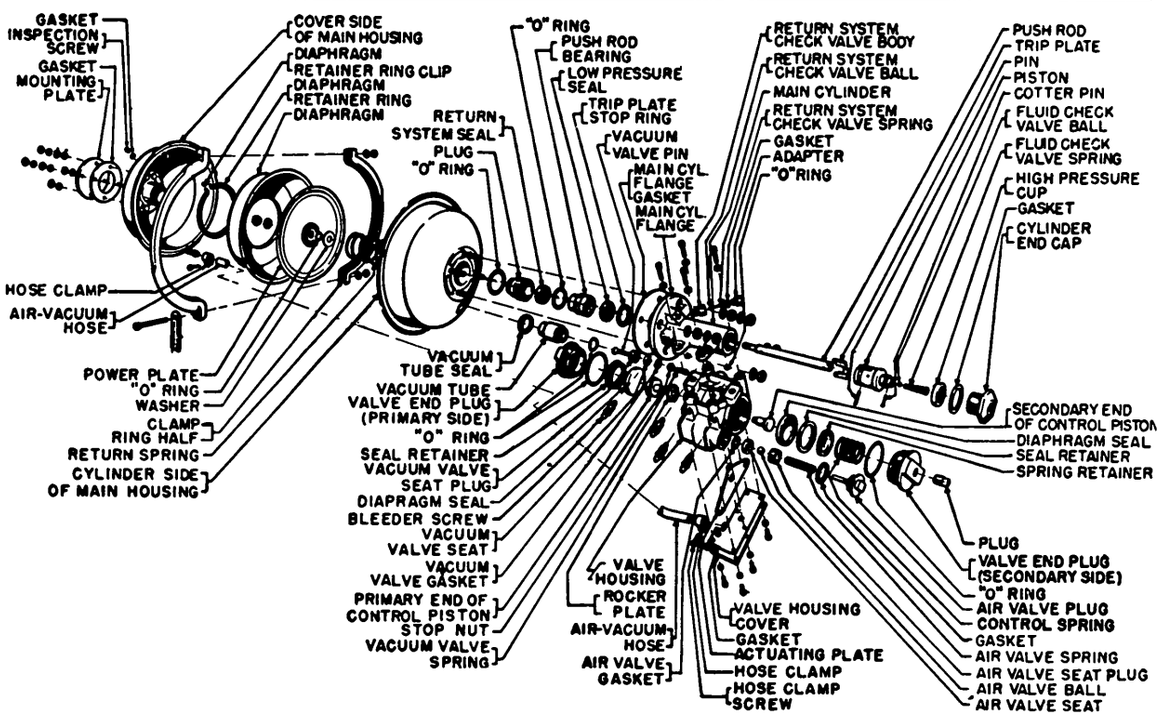
5) Remove assembly from vise and press guide sleeve end down on bench to hold piston and guide in fully applied position while tightening hydraulic cylinder stud nuts evenly. Power piston must move freely when all nuts are tight.

TYPICAL BUICK BRAKE POWER UNIT ASSEMBLY

CHRYSLER VACU-EASE BRAKE POWER UNIT

Chrysler Six & Eight (1954)
D Soto (1954)
Dodge Six & Eight (1954)

DESCRIPTION: -The valve housing and cylinder unit are mounted as an assembly on one end of the main diaphragm housing. The valve housing assembly controls the relative air pressures on both sides of diaphragm. Fluid return system built-in **NOTE**—The External Valve Type unit can be used to replace the Internal Valve Type by using an Adapter Kit, Chrysler Part No. 1321149.



ADJUSTMENT: None required.

►*CAUTION:* Repair of the vacuum and air valves in the field is not recommended by the manufacturer, since these parts are specially calibrated.

EXTERNAL VALVE TYPE UNIT OVERHAUL: After removing the unit from the car, proceed as follows. ***Cleanliness is extremely important.***

Disassembly: Clamp unit in vise (grip four mounting screws). Loosen cylinder end cap and clamp on hose. Remove four Allen head screws holding valve housing to cylinder, and remove housing. Invert the unit, mark both halves of housing, remove clamp ring and disassemble cover side of main housing from cylinder side. Remove hex nut from center of power plate and lift off plate and diaphragm assembly. Remove small "O" ring and washer from end of push rod and remove return spring. Remove the four cylinder-to-main housing nuts, and remove cylinder. Clamp cylinder in vise with push rod end up. Screw special protective "thimble" (included in repair kit) on threads of push rod end, unscrew return system seal retaining plug and remove it. Pull the push rod out of the cylinder. Remove cylinder end cap and examine cylinder walls. Remove light scratches with crocus cloth, and clean with alcohol. Replace badly scored cylinders. Remove cotter pin, fluid check valve ball and spring, and bronze bearing from push rod.

Reassembly: Remove secondary cup from piston being careful not to scratch the anodized aluminum surface, and replace with a new one. Drop check valve ball in piston, install ball spring (small end to ball) and install cotter pin. Lubricate piston and cylinder with brake fluid, insert push rod and piston assembly from cap end of cylinder. Install cylinder cap with new copper gasket, finger tight. Clamp cylinder, push rod end up in vise, and install stop plate washer. Remove primary cup from inside bronze bearing, and "O" ring from outside of bronze bearing, and replace with new cup and ring. Lubricate bronze bearing and slide into cylinder over push rod with primary cup down. Press down lightly with thumb. Lubricate inner lip of retaining seal, slide seal and plug assembly over end of push rod. Screw retaining plug into cylinder and tighten. Place cylinder in vise and tighten end cap to 110 ft. lbs. torque. Remove special thimble nut from threads on push rod. Replace "O" ring seal, and cylinder flange gasket between cylinder and main housing. Remove cylinder from vise and assemble to main housing with flat side of cylinder facing the short studs. Install lock washers and nuts and tighten to 150 ft. lbs torque. Clamp assembly in the vise with push rod end up, and install flat washer first, and a new small "O" ring on end of push rod. Install spring in boss of power plate and press plate and diaphragm down over end of push rod against spring. Secure assembly to push rod with nut and lock washer tightened to 40 inch pounds torque. Assemble the two halves of the housing (lining up marks). See that cross-over tube rests in slot in cylinder side of main housing. Install clamp ring. Tighten clamp ring bolts, being careful to center cross-over line between ears of clamp ring. Pull vacuum tube out of valve housing and replace "O" ring and rubber grommet. Lubricate "O" ring only, and re-install vacuum tube, "O" ring first, into valve housing. Replace "O" rings used between valve housing and cylinder. Reconnect housing hose. Fasten the valve housing to cylinder.

VACU-EASE BRAKE POWER UNIT (EXTERNAL VALVE TYPE)

TROUBLE SHOOTING: Brakes do not Release Properly—With engine **running**, check the brakes for release If not released, crack line from master cylinder to power unit If this releases brakes, trouble is **not** in power unit If brakes not released, crack hydraulic line at end of cylinder of power unit (line between power unit and wheel cylinders) If this releases brakes, power unit is at fault (missing inspection screw or gasket on main housing cover)

Unit does not Boost: With engine running, press the pedal down and listen for a rush of air through the power unit air cleaner If no rush of air is heard, check if vacuum is present at the unit by disconnecting the line If no vacuum is reaching the unit, check for plugged line, or defective vacuum check valve (at the engine manifold) If a rush of air is heard at the unit air cleaner when the pedal is depressed and booster still is inoperative, it indicates the fluid check valve is not seating properly If with engine running, a continuous rush of air is heard, without operating the brake pedal, it indicates the diaphragm punctured or cross-over line between valve housing and cover is leaking.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "INTEGRAL TYPE" POWER UNIT

Chrysler & Imperial (1955)
De Soto (1955)
Dodge (1955–56)
Plymouth (1955–56)

DESCRIPTION: Integral type, self-contained, vacuum-suspended, power braking device using engine intake manifold vacuum and atmospheric pressure for its power. Unit incorporates air-vacuum housing, hydraulic cylinder, fluid reservoir, air cleaner, and vacuum check valve. Unit is mounted on dash above brake pedal.

OPERATION: With engine running, brakes unapplied, both sides of power piston are under a vacuum. Application of brake pedal causes atmospheric port to open, forcing power piston forward and thereby exerting a thrust on hydraulic plunger. This increases line pressure to the four wheels. Release of brake pedal restores vacuum balance in power cylinder.

CHECKING & ADJUSTMENT: Check all parts of the power brake system before disassembling the Power Unit whenever brake trouble experienced.

Adjustments: No adjustment of Power Unit for free play or return stop is required. Unit has built-in pedal return spring and a pedal return stop. Pedal height and travel are determined by the combined length of the pushrod and pushrod end (clevis) which are adjustable.

Pedal Height & Travel Adjustment (Unit on Car)– Slide scale next to boot, inside of pedal bracket up to and against dash panel, and measure distance back to center line of clevis pin. Distance should be 8 57/64" (Chrysler), 8 23/32" (Others). If not, re-adjust clevis on rod, re-tighten clevis jam nut and re-check dimension.

Pedal Height & Travel Adjustment (Unit Off Car)– Measure from reinforcing plate mounted on unit to center line of hole in rod end (clevis). Dimension should be 8 61/64" (Chrysler), 8 25/32" (Others).

►*PEDAL ADJUSTMENT NOTE:* It is suggested that for greatest braking efficiency, driving ease, and comfort, that brake shoes be kept well adjusted to maintain maximum pedal reserve with brakes applied.

BLEEDING BRAKES: Using a pressure bleeder attached to fluid reservoir of unit, bleed system from bleeder screw immediately forward of the reservoir on top of hydraulic cylinder of unit, then at the four wheel cylinders. When fluid runs clear at all points, start engine, pump brake several times, and then re-bleed system. After bleeding completed, check for leaks in brake system while applying heavy brake pressure with engine running. *NOTE*–After bleeding system, fill reservoir to no higher than 1/8" below filler cap neck.

LUBRICATION: Check level of brake fluid in reservoir every 1000 miles. Fill reservoir to no higher than 1/8" below filler cap neck.

TROUBLE SHOOTING: Before checking power brake unit for source of trouble check remainder of brake system.

Pedal Fails to Return: Overall width of pedal hub plus nylon bushing flanges exceeds length of pedal pivot spacer pinching the hub and bushings; bind of nylon bushings.

Brake System Loses Fluid: Loose or broken connections in brake hydraulic system; worn or damaged primary cup, primary cup seal and dome cup.

Brakes Do Not Release Properly: Pedal fails to return properly; plugged compensating holes in power piston sleeve; damaged or weak power piston return spring, air valve control spring, or reaction spring; excessively dry air valve "O" ring; brakes improperly adjusted; insufficient brake fluid in system; dust boot retainer on air cleaner cover is not concentric with power piston guide sleeve.

Unit Does Not Boost: (*NOTE*–To determine if unit operating, test as follows: With engine stopped, depress brake pedal several times to eliminate all vacuum from system. Apply brakes, and while holding foot pressure on brake pedal, start the engine. If unit operating, pedal will move forward when engine vacuum power is added to pedal pressure). Possible causes for brake not boosting: Bent, broken or obstructed vacuum source line from engine manifold to check valve, or a faulty vacuum check valve; blocked air passage in power piston guide sleeve or in air cleaner element; jammed air valve seat assembly in power piston due to foreign material becoming lodged in power piston air valve seat bore cavity; damaged secondary cup.

Loss of Pedal: Dirt or foreign material lodged between outside lip of secondary cup and cylinder bore.

Brakes "Touchy" or "Grabby": Inspection screw missing on air side of diaphragm; grease, fluid or moisture on brake linings; brakes improperly adjusted.

"Spongy" Pedal: Air in brake lines or in hydraulic cylinder on power unit.

Pedal Travel Too Great: Improperly adjusted brakes; air in brake system.

REMOVAL & INSTALLATION: Remove clevis pin attaching pushrod to power lever. Disconnect hydraulic line at power brake unit. Disconnect vacuum line at power brake unit. Disconnect stop light switch wires. From passenger compartment side, remove nuts from power brake unit two lower studs which extend from power brake unit through dash panel and pedal mounting bracket. Then remove four nuts on engine side of dash panel which hold reinforcement to dash panel. This will allow removal of reinforcement and power brake unit as an assembly. Remove power brake unit assembly from reinforcement by removing two upper stud nuts. At same time, this allows air cleaner cover and air cleaner to be removed. To install, reverse removal procedure. *NOTE*–Before reinstalling unit on car, check brake pedal linkage for freedom of movement. Refill master cylinder.

OVERHAUL: *NOTE*–After removing brake unit and before starting disassembly operations, remove reservoir filler cap and gasket, pour out brake fluid and discard it. Stroke unit at least two applications to dissipate vacuum and to pump out as much of remaining fluid as possible through wheel cylinder connection. Stop light switch in boss on bottom of hydraulic cylinder should not be removed except for replacement or to correct a fluid leak.

Disassembly: Major Components–Remove pushrod from unit by sliding pushrod boot down on rod and clamping end of pushrod in vise, then, gripping lower unit firmly, pull it away from pushrod with a quick jerk. (*NOTE*–Pushrod is held in place by pushrod retainer clip, which cannot be re-used. Whenever pushrod removed from unit, new retainer clip must be used at reassembly). Open boot retainer strap and remove pushrod boot and air cleaner cover boot. Discard retainer strap. Clamp unit in vise with hydraulic cylinder end down. Vise should be clamped on hydraulic cylinder only tightly enough to hold securely; clamping too tightly will crack or distort cylinder. Remove reinforcement plate, then air cleaner cover assembly by removing four hex nuts and lockwashers. With cover assembly removed, lift out four spacers and air cleaner core. Disassemble body assembly by removing two clamp rings. To facilitate correct reassembly, loosen both clamp ring screws but remove only one, keeping the two clamp ring parts held together in their proper relationship. (*CAUTION*–Be sure to lift straight up while holding power piston guide sleeve down against return spring. Valve side of body assembly should slide straight up and off of power piston guide sleeve). Remove power piston and guide assembly from body assembly by lifting straight up. This is important to prevent damage to power piston sleeve and bearing. If edge of diaphragm did not free itself from flange of body assembly, hold power piston and guide down against return spring while loosening edge of diaphragm. Then allow return spring to lift power piston and guide assembly. Remove return spring. Remove hydraulic cylinder assembly off of body assembly. Remove and discard cylinder-to-body seal.

Body Assembly (Cylinder Side)– Remove vacuum check valve assembly, then remove and discard check valve-to-body "O" ring. Position check valve assembly in vise clamping on large hex on body, to remove check valve body cap. Lift out check valve spring and floating valve assembly, but **do not** discard spring.

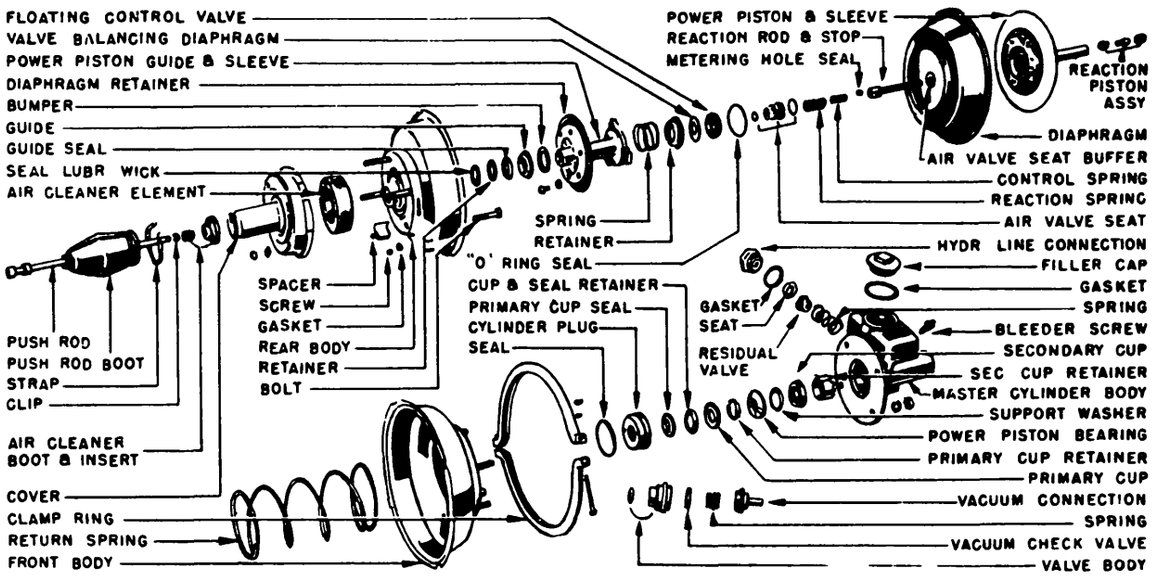
Body Assembly (Valve Side)–From hub of body assembly, valve side remove and discard guide seal and seal lubricating wick. This can be done with small pointed pliers, using care not to damage guide bearing or wick retainer. Examine inspection screw and gasket; remove only if damaged or not sealing properly.

Power Piston & Guide Assembly–Place power piston and guide assembly in holding fixture, with power piston and guide end up. Lift guide return bumper from guide sleeve, and discard, but note its thickness. It is important that the new bumper be the same thickness as the one removed (Except on very early production, the thicker bumper is smooth on both sides). Remove diaphragm retainer and diaphragm. Lift guide assembly off of power piston assembly, and remove and discard "O" ring seal from between these two assemblies. Remove and discard floating control valve assembly, and valve balancing diaphragm, but **do not** discard spring, or spring retainer. With power piston assembly still in holding fixture, lift out air valve seat assembly and discard. Lift out control spring and reaction spring. Lift out reaction rod assembly. Remove and discard metering hole seal and buffer. Remove power piston assembly from holding fixture, insert a drift

CONTINUED ON NEXT PAGE

CHRYSLER, DESOTO, DODGE PLYMOUTH "INTEGRAL TYPE" POWER UNIT (Cont.)

pin into center of power piston, and push out reaction piston insert and dome cup assembly. Using extreme care to avoid marring reaction piston or dome cup insert, remove and discard reaction cup. Reaction piston and cup insert can be popped out of cup by pinching dome between thumb and forefinger.



Hydraulic Cylinder Assembly—Place cylinder assembly in vise with flange end up. Do not clamp tightly. Using a face spanner wrench, remove cylinder plug assembly. Disassemble cylinder plug assembly by hand by removing primary cup, retainer and primary cup seal from cylinder plug. Primary cup is easily removed by gripping inner cup lip between thumb and forefinger. Discard cup and seal, **do not discard retainer.** From hydraulic cylinder, lift out primary cup retainer, power piston bearing, and secondary cup support washer. Then remove secondary cup only and lift out secondary cup retainer. With cylinder clamped in vise, remove secondary connection plug, and residual check valve seat. Then lift out residual check valve assembly and valve spring. Discard residual check valve assembly and seat.

Cleaning & Inspection: Before any part of unit is reassembled, all metal parts must be thoroughly cleaned with diacetone alcohol or clean brake fluid and wiped dry. Avoid allowing dirt or grit to get into unit during reassembly. When assembling unit, be sure to discard all parts specified and other damaged parts, replacing them with NEW, clean parts.

Reassembly: Hydraulic Cylinder Assembly—1) Position hydraulic cylinder in vise with secondary connection boss facing up. Insert residual check valve spring and new residual check valve assembly. Place new residual check valve seat on residual check valve; center carefully. Assemble secondary connection plug and new gasket to hydraulic cylinder. Torque to 125 ft. lbs. Position hydraulic cylinder in vise with flange end up, and wet inside of cylinder with brake fluid. Then insert secondary cup retainer, small end up, being sure that it rests evenly on hydraulic cylinder bore. Then, after wetting new secondary cup with brake fluid, insert it into cylinder. Cup lips must be down, be sure that cup lip is not turned back at any point as cup slides into cylinder. Place secondary cup support washer in position on secondary cup.

2) Insert power piston bearing into cylinder on top of secondary cup support washer. Notched face of bearing must face up, and bearing must be centered in cylinder bore Place primary cup retainer, notched edge down in hydraulic cylinder, centering it on notched surface of power piston bearing *(This is very important).* Be sure that retainer is centered as closely as possible by eye, so it will not be damaged when cylinder plug assembly is installed.

3) Assemble cylinder plug assembly by inserting new seal, seal retainer flat side out, and new primary cup in that order. Both seal and cup must enter plug with lips facing out. Use finger to force outside lip of both seal and primary cup down and outward against bore of plug to insure sealing contact. Install cylinder plug assembly into hydraulic cylinder using a face spanner wrench. Torque to approximately 25 ft. lbs.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "INTEGRAL TYPE" POWER UNIT

Guide Assembly—Inspect end of guide casting where it seats against air valve seat assembly. This must be smooth and clean. Position guide assembly in holding fixture with sleeve end down. Then assemble new valve balancing diaphragm on new floating control valve—after wetting outside diameter of diaphragm slightly with hydraulic brake fluid. Press spring retainer over diaphragm and floating valve assembly, using thumb pressure only. Then wet inside diameter of diaphragm slightly with hydraulic brake fluid and place spring on retainer. Press complete assembly down on power piston guide stop Also install new power piston-to-guide "O" ring seal on power piston guide hub

Power Piston & Guide—1) Assemble stainless steel reaction piston into bronze dome cup insert Small diameter of bronze insert must be toward spherical end of reaction piston

2) Assemble new pre-greased dome reaction cup over spherical end of reaction piston and insert assembly. Force cup back firmly to insure snug fit of cup bead in groove of insert Place power piston and sleeve assembly on bench, sleeve end up, and after lubricating outside diameter of reaction cup with brake fluid, press reaction piston, insert end dome cup assembly into power piston sleeve, dome out. Use care to avoid damaging cup Press down into sleeve firmly until it bottoms. Check to be sure that outside diameter of reaction cup is not obstructing compensating ports, and that all these port holes are open and clean

3) Assemble new buffer and new metering hole seal to reaction rod and stop assembly. Invert power piston and sleeve assembly and place it holding fixture, sleeve end down, then drop complete reaction rod assembly into center of power piston.

4) Place reaction spring in center of reaction stop cavity, and control spring around outside of reaction stop, in power piston cavity.

5) Install new air valve seat "O" ring seal in groove on outside diameter of new air valve seat assembly using care to preserve silicone grease on seal (This seal is supplied pre-greased in cellophane envelope in kit)

6) Install complete air valve seat assembly in center of power piston cavity, over control spring reaction spring and reaction rod stop. Use a twisting motion as seal enters bore of power piston Then use thumb pressure to test air valve seat springs for freedom of movement, *(NOTE*—Air valve seat is steel, power piston cavity is aluminum casting, use extreme care to avoid any damage or marking, especially on aluminum vacuum valve seat.).

7) Position diaphragm retainer over guide and sleeve assembly, with three of the six holes in the retainer lined up with three holes in guide. Position diaphragm on flange of power piston and sleeve assembly with flange of diaphragm down Be sure that inside diameter of diaphragm is nested snugly all around in groove of power piston flange.

8) With power piston diaphragm retainer and guide assembly held directly above power piston assembly, insert pushrod without retaining clip through center bore of guide and into pushrod cavity in center of air valve seat assembly. Then, holding air valve seat down against control and reaction springs, position guide assembly so that three holes in guide line up with three holes (tapped) in power piston. Be sure that "O" ring seal is properly positioned between guide and power piston

CONTINUED ON NEXT PAGE

CHRYSLER, DESOTO, DODGE PLYMOUTH "INTEGRAL TYPE" POWER UNIT (Cont.)

9) Install three lockwashers and hex bolts through holes in diaphragm retainer and into tapped holes in power piston. Tighten all three bolts evenly to torque of 90-100 **in. lbs.** Using pushrod, check for freedom of movement of air valve seat against control and reaction springs.

10) Place new rubber guide return bumper over guide sleeve and press firmly down on hub of guide. *NOTE*–A kit, available from Chrysler Corporation Parts Division, contains two guide return bumpers, each of a different thickness. It is important to install the bumper which is the same thickness as the one that was taken out of unit at disassembly.

Body Ass mbly (Valv Side)–With body assembly, valve side resting on bench, hub end up, insert new guide seal into hub, being sure that lips of seal are facing up, away from bearing, and that seal is installed between bearing and wick retainer which is inside hub. *(NOTE*–Seal will slip easily into place if held between thumb and forefinger, in an elliptical shape and inserted through hub of body. This seal is supplied pre-greased in a cellophane envelope in the repair kit). Insert new wick into hub in same manner as seal was inserted, using care to preserve grease on wick. After wick installed, be sure that wick retainer is positioned snugly against wick and away from cup lips. Apply any grease remaining in seal and wick envelopes to inside of hub, to provide maximum lubrication for seal, wick, and guide bearing. Check inspection screw and gasket to be sure they are tight.

B dy Ass mbly (Cylinder Side)–Position vacuum check valve body in vise and insert new floating valve assembly, being sure that bonded rubber seal is facing down, against seat. Then assemble spring and cap.

R ass mbly of Major Components–1) Place new cylinder-to-body seal in groove around cylinder plug assembly, being careful to avoid twisting seal.

2) Assemble hydraulic cylinder assembly to body. Position cylinder on body in such a way that, when viewing assembly from cylinder end, vacuum check valve is to left of hydraulic cylinder. Then assemble hex nuts and lockwashers to studs, finger tight only.

3) Position cylinder assembly with body assembly, cylinder side, in vise with cylinder end down and body assembly flange facing up. Place return spring in body assembly, centering it around cylinder plug assembly and inside the four cylinder flange bolt heads in housing.

4) Assemble power piston and guide assembly to body assembly, valve side, by inserting guide sleeve through hub of body assembly. Be careful to avoid damaging felt wick in hub.

5) Hold assembled power piston and guide assembly and body assembly, valve side, by guide sleeve, which now protrudes out of hub of body. Wipe power piston sleeve with brake fluid, then carefully position power piston on return spring so that spring nests around shoulder of power piston.

6) Press power piston and guide assembly down into unit against return spring, watching to avoid misalignment as power piston sleeve enters bore of cylinder plug assembly. Holding power piston and guide down against spring, place edge of diaphragm in groove on flange of body assembly, valve side, over edge of diaphragm and flange of body assembly, press firmly into position.

7) With two sides of body assembly properly mated, place two half-ring clamps over body flanges, being sure that flat portion of rings match cutaway portions of body flanges. Fasten half-ring clamps with two clamp ring screws, lockwashers and hex nuts. Tap ring clamps snugly into place with a rubber mallet, then tighten securely. "Do Not Lubricate" tag should be attached on either side of unit, under one of these two nuts. *(NOTE*–Two sides of body assembly must be assembled so that notches on one side mate with keys on other, and the cutaway portions of the flanges match).

8) Press power piston and guide assembly down as far as possible against return spring three or four times to be sure that power piston sleeve and hydraulic cylinder are properly centered. Remove unit from vise, invert, and while holding unit down to push power piston and guide assembly into fully applied position, tighten evenly the four cylinder flange nuts, using a torque of 180-200 **in. lbs.** After all flange nuts are tight, power piston and guide assembly must return freely to "off" position as soon as pressure is released. If power piston does not return freely, loosen cylinder flange nuts and re-align cylinder to housing; then retighten nuts and test again for free return.

9) Return unit to vise then blow out or replace air cleaner core, centering it around hub of body assembly. Then place one spacer around each of four mounting bolts.

10) Assemble air cleaner cover assembly to unit over air cleaner core and spacers, position cover so that air inlets will face down when unit is mounted in position on vehicle. Assemble reinforcement plate to unit over air cleaner cover assembly, positioning plate so that its longest dimension will be below unit when mounted in position on vehicle. Install four lockwashers and hex nuts and tighten securely to torque of 180-200 **in lbs.** Be sure guide sleeve and air cleaner cover sleeve are concentric. If necessary, tap cover sleeve lightly with rubber mallet to align.

11) Insert pushrod into pushrod boot, then into air cleaner cover boot, and insert assembly and snap NEW pushrod retainer clip into position on small end of pushrod. Be sure that small end of boot is nested snugly in groove on outer end of pushrod.

12) Holding boots back toward outer end of pushrod, press pushrod with retainer clip straight down through center of guide sleeve and into air valve seat cavity. Exert approximately 40 lbs. of pressure until end of pushrod snaps into place. When properly installed, pushrod is held securely enough in place so that it can be used to lift the weight of the unit.

13) Fit boots on flange of sleeve of air cleaner cover assembly, first the boot cover assembly, then the pushrod boot, being sure that they fit snugly. Then install new boot retainer strap. Reinstall bleeder screw and reservoir filler cap and gasket. Also reinstall stop light switch if it has been removed. Be sure all are in position and secure before reinstalling on vehicle.

CHRYSLER, DE SOTO, DODGE PLYMOUTH "BELLOWS TYPE" POWER UNIT

Chrysler & Imperial (1956-60)
D Soto (1956; S-26 Adv. 1957; 1959-60)
D dg (1956, 1959-60)
Plym uth (1956-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*1956 BRAKE PEDAL RETURN SPRING & CONTROL VALVE SPRING PRODUCTION CHANGE (To Improve Low Temperatur Operation):* New "Kelsey-Hayes" Power Brake Unit No. 1731216 replaces Unit No. 163-7814. New Unit identified by daub of green paint on front outer bellows cover plate. It includes a New Control Valve Spring No. 1676486 and requires the use of New Pedal Return Spring No. 1730077. Both springs are painted green and must be used together. Use Pedal Return Spring painted black with power units not daubed with green paint.

►*1959 PLYMOUTH POWER BRAKE SQUEALING OR WHISTLING NOISE CORRECTION:* Install a new type vacuum check valve, Part No. 1944089 (identified by a daub of white paint on flange of tube section). This new valve is a "T" design which permits a single hose connection to reserve tank in place of the two hoses previously used. To determine if the old valve is faulty, check for looseness of suction tube flange in the valve assembly.

DESCRIPTION: This "Assist Type" power brake unit consists of an oval shaped air-vacuum bellows, control valve, and push rod. A control valve operating rod extends through the push rod and actuates the brake unit control valve. The unit is mounted on the engine side of the dash panel and is connected mechanically to the brake pedal linkage. A trigger arm on brake lever operates the control valve through the valve operating rod. In the event of power failure, normal manual brake action is assured as the brake pedal lever pin is free to slide in slot of power piston rod yoke when brake pedal is depressed.

OPERATION: Vacuum from the intake manifold is applied to unit, and air is evacuated from the air-vacuum bellows through the vacuum valve during brake application. When brakes are released, air (atmosphere) enters the unit through the built in air cleaner and is regulated by the air valve. The valve operating rod, which is controlled by the pedal, overcomes the spring pressure of the air valve and keeps atmospheric pressure inside the air-vacuum bellows. The return spring extends the bellows completely whenever brakes are not applied.

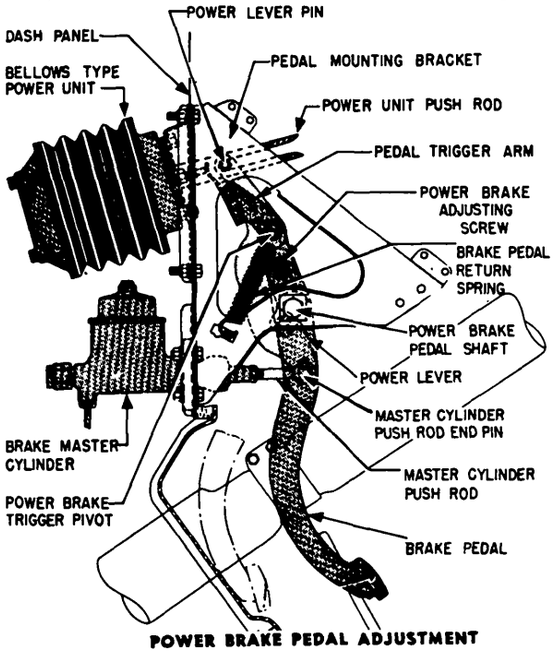
ADJUSTMENT: It should seldom be necessary to adjust brake pedal trigger arm. For adjustment of Pedal Free-play and for Trouble Shooting, see below.

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "BELLOWS TYPE" POWER UNIT (C nt.)

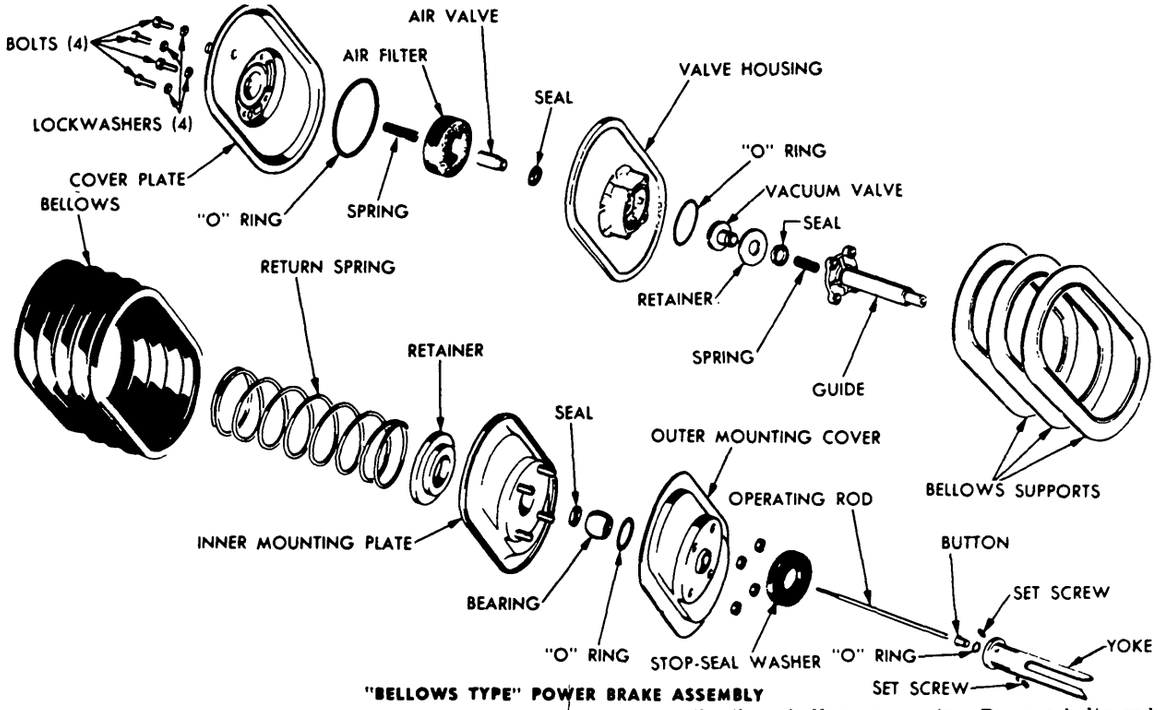
Pedal Freeplay: Check adjustment as follows: Remove vacuum hose from power unit and press brake pedal several times to eliminate all vacuum in unit. Insert a screwdriver blade between rubber collar of power brake trigger pivot and rear side of elongated hole in power brake lever, forcing them apart. *NOTE - If brake pedal l ver and power brake lever are not held apart, a false freeplay setting will be obtained.* Check the freeplay with linkage in this position by pushing lightly at pad end of brake pedal. Pedal freeplay should be between 1/16" & 1/8". *NOTE - This specification supersedes previous adjustment of 1/32-1/8" on Chrysler and DeSoto models.* Adjust as necessary by shortening or lengthening the master cylinder pushrod.

Trouble Shooting: If operation not satisfactory, correct by turning adjusting screw not more than 90° either way from original setting as follows:



Slow Pedal Release - Rotate adjusting screw counterclockwise.

Time Delay During Fast Application: Rotate adjusting screw clockwise.



P dal Vibrates (Unit Chatter): Rotate adjusting screw counterclockwise.

CAUTION - Adjusting screw should not be turned more than 90° from vertical (arrow up).

REMOVAL: *(CAUTION – Before removing brake unit, place a wood wedge between brake power lever and the forward edge of triangular opening in brake pedal lever bracket to prevent trigger arm from extending through hole in dash panel which would cause damage to trigger arm).* Remove the nuts and lockwashers mounting unit to dash panel. Pull unit and mounting plate straight out and away from panel, using care not to lose the nylon bushings on pedal linkage pin which engage power unit yoke.

POWER BRAKE PEDAL ADJUSTMENT

"BELLOWS TYPE" POWER BRAKE ASSEMBLY

DISASSEMBLY: 1) Remove nuts attaching mounting plate to power unit and remove plate. Remove and discard "O" ring on mounting plate. With an Allan wrench loosen the two setscrews and remove yoke from power unit shaft. Discard the valve operating rod bottom seal.

2) Remove nuts attaching outer mounting plate. Using a screwdriver, gently pry up plate to loosen, and remove plate. Discard "O" ring seal. Compress bellows by hand sufficiently to remove the guide bearing. Remove and discard seal from inside bearing. Peel back outer lip of bearing completely around inner mounting plate (keep one hand on inner plate to keep it from snapping up). Remove plate and lift out return spring and retainer.

3) Place unit on its side and remove bolts and lockwashers attaching valve cover to valve. Lift off valve cover (if necessary, use a flat blade to separate cover plate from bellows flange). *(CAUTION – Use extreme care to avoid marking or scratching inner face of plate where it contacts bellows flange).* Remove "O" ring from valve cover and discard it. Remove air valve spring from center of valve, then remove the air filter. Slide air valve out of valve housing *(NOTE* – It may be necessary to make a small hook from a paper clip to remove valve).

4) Place valve housing end down on bench, then remove bellows from valve, by peeling back the outer lip of bellows. If a new bellows is to be installed, remove the three bellows supports. Remove bolts and lockwashers attaching guide to valve body. Lift out guide to expose vacuum valve, valve spring and seals. Discard seals. Remove vacuum valve and retainer and discard housing to guide seal. Invert valve housing and remove valve seal from its groove in valve body. *(CAUTION – If using a sharp instrum nt or pointed pliers, be very careful not to mark or scratch insid diameter bore of valve housing).*

REASSEMBLY: Clean all parts except bearing, bellows, and filter and blow dry with air. Bellows may be cleaned with mild soap and water if necessary. Inspect all parts for damage and replace all defective parts. During reassembly, use new "O" and seal rings.

1) Insert a new air valve seal into bore of valve housing (lips of seal facing out when installed). Carefully position a new vacuum valve in retainer. Invert valve housing and install valve and retainer. Press down firmly on retainer to snap in place. Position a new valve housing to guide seal in groove provided. Install a new vacuum valve seal in bore of guide, with lips of seal toward bottom of bore.

2) Install the vacuum valve spring in center of valve (smallest). Position guide over vacuum valve, lining up bolt holes in guide with bolt holes in valve body. Carefully lower guide down against valve body, making sure that tapered portion of vacuum valve enters seal evenly. Press down on guide to seat, then install bolts and lockwashers. Tighten evenly and securely. *(CAUTION – B sur that countersunk holes at nd of guide line up with the long cent rline of valve housing).*

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "BELLOWS TYPE" POWER UNIT (C nt.)

3) If a new bellows is being installed, position the supports in bellows (bellows supports must be centered in the three center accordian folds and aligned with bellows and each other) Using holding fixture (made from a piece of four inch pipe) to support the guide and valve assembly, install the bellows *(CAUTION – Be sure the arrows on edg of bellows and housing are aligned).*

4) With the bellows in the holding fixture, lightly coat the outside surface of the air valve with silicone grease (do not use any other kind), then insert the **small end first** into bore of valve housing Use finger pressure to test for free movement of valve against vacuum valve spring. Install air valve spring in recess in air valve and filter. Install a new valve housing cover "O" ring on shoulder of valve body hub. Position valve cover over housing, with notch in edge of cover matching arrow on bellows. Be sure that air valve spring nestles on dimple in center of cover. Press cover down evenly over valve housing to seat cover "O" ring. Install bolts and tighten securely.

5) Remove assembly from holding fixture and invert unit Coat guide lightly with silicone grease, then install return spring. Position the spring evenly around hub of valve housing and guide. Place spring retainer and inner mounting plate over spring, being sure that arrow stamped on plate is in line with arrow on edge of bellows. Compress return spring, then fold edge of bellows over edge of plate so it fits evenly around plate

6) Install a new guide bearing seal in groove inside bearing bore (seal must seat snugly in bearing). Using silicone grease, lubricate inside of bearing, then slide over guide while compressing bellows, (bearing must be installed with lip of seal facing out). Push bearing down over guide and into pocket of plate. Release bellows (bearing will ride up guide with plate into position. Install the bearing to mounting plate "O" ring, then lower outer mounting plate down onto assembly (the notch in edge of plate must be in line with arrows on bellows) Install nuts and draw down finger tight.

7) Slide a new valve operating rod seal ring over nylon bumper on end of rod and into groove, then install rod in center of guide. Press on end of guide to test for free operation of air and vacuum valves (a 'two-step" movement should be felt when rod depressed and released fully). Place a new stop seal washer in position and install yoke on end of guide Compress bellows slightly, then alternately tighten set screws (hub of yoke must be down snug against shoulder of guide, with the setscrews aligned with tapered holes in guide). Tighten mounting plate nuts securely Place mounting bracket in position, with long center line of bracket at right angles to long centerline of power unit The off set of the bracket must be so that when installed in car, the axis of the unit will be inclined down toward front of car Install lockwashers, nuts and tighten securely

INSTALLATION: Be sure that unit is so placed that its axis inclines down toward **front** of car and that vacuum inlet connection is toward engine As the yoke passes through dash panel, be sure that it engages pedal linkage correctly by sliding over nylon bushings on power brake lever cross pin Install mounting plate nuts and tighten securely

CHRYSLER, DE SOTO "PISTON TYPE" POWER UNIT

Chrysler & Imperial, All Models (1956)
DeSoto, All Models (1956)

►CHANGES, CAUTIONS, CORRECTIONS

► *1956 VALVE ROD & PEDAL RETURN SPRINGS PRODUCTION CHANGE (To provide more positive action)* New "Bendix" Power Brake Unit No. 1731217 replaces former Unit No. 1671546 and contains a new Valve Rod Spring No. 1676487, and requires the use of new Pedal Return Spring No. 1730077. Both new springs are painted green and must be used together. *NOTE - This new Unit No is stamped on Air Cleaner Cover but is not the Air Cleaner Cover No.*

► *1956 INTERMITTANT BOOSTER ACTION CORRECTION* Inspect booster valve rod at point where it contacts trigger arm. Wipe off all lubriplate, check to see that rubber dust shield is properly placed with 1/8" clearance between shield and nylon button. If sticking condition not corrected, replace Valve Rod Spring with Spring No. 1676487 (painted green) and Pedal Return Spring with Spring No. 1730077 (painted green). Both springs must be used together.

DESCRIPTION: The "Assist Type" power unit consists of a vacuum cylinder, piston operated push rod, and control valve assembly which is integral with piston assembly The unit is mounted on the engine side of the dash panel and connected mechanically to brake pedal linkage through the power brake unit push rod A valve operating rod within the piston rod is operated by a trigger arm on upper end of brake pedal lever In the event of power failure, normal manual brake action is assured as the brake pedal lever pin is free to slide in slot of power piston yoke when brake pedal depressed

OPERATION: With brake pedal released, both sides of vacuum cylinder piston are open to the atmosphere Application of brake pedal causes vacuum port to open, forcing piston toward rear and exerting a thrust on power lever of brake pedal lever assembly which causes master cylinder to be applied. The amount of pressure exerted on master cylinder push rod is in proportion to distance brake pedal is depressed.

ADJUSTMENT: It should seldom be necessary to adjust brake pedal trigger arm For adjustment of Pedal Freeplay and for Trouble Shooting, see below.

Pedal Freeplay: Check adjustment as follows Remove vacuum hose from power brake unit and press brake pedal several times to eliminate all vacuum in unit Insert a screwdriver blade between rubber collar of power brake trigger pivot and rear side of elongated hole in power brake lever, forcing them apart *NOTE - If brake pedal lever and power brake lever are not held apart, a false freeplay setting will be obtained.* Check the freeplay with linkage in this position by by pushing lightly at pad end of brake pedal Pedal freeplay should be between 1/16-1/8". *NOTE - This specification supersedes previous adjustment of 1/32-1/8" on Chrysler and DeSoto models.* Adjust as necessary by shortening or lengthening the master cylinder pushrod

Trouble Shooting: If operation not satisfactory, correct by turning adjusting screw not more than 90° either way from original setting as follows

Slow Pedal Release - Rotate adjusting screw counterclockwise

Time Delay During Fast Application: Rotate adjusting screw clockwise

Pedal Vibrates (Unit Chatter): Rotate adjusting screw counterclockwise

CAUTION - Adjusting screw should not be turned more than 90° from vertical (arrow up).

REMOVAL: *(CAUTION – Before removing brake unit, place a wood wedge between power brake lever and the forward edge of triangular opening in brake pedal lever bracket to prevent trigger arm from extending through hole in dash panel which would cause damage to trigger arm).* Disconnect vacuum hose at power unit and remove complete power unit and bracket after removing the four nuts and lockwashers attaching it to dash panel.

INSTALLATION: Position power unit on dash panel so that its axis inclines down toward front of car. As yoke passes through dash panel, be sure that it engages the pedal linkage correctly by sliding over the nylon bushings on power brake lever cross pin. Replace the attaching bolts and nuts and tighten securely. Remove wedge from pedal bracket.

DISASSEMBLY: *(CAUTION – Do not clamp piston rod or yoke in vise during service operations).* During disassembly of the power unit, scribe lines on all component parts before removing to insure correct reassembly.

1) Remove air cleaner cover screws, cover and filter material Remove remaining plate screws and separate vacuum tube from plate, remove plate and gasket from cylinder Slide end of hose from vacuum tube Remove the four bolts and nuts from end plate and remove cylinder shell and rubber ring gasket. Remove hose from vacuum plate and rubber diaphragm from end of tube fitting Using thin nose pliers, pull out diaphragm balancing pin. Remove tube and plate attaching screws, separate tube and valve poppet parts from piston plate. Separate plate, poppet spring, and diaphragm from poppet From opposite end of assembly remove valve rod rubber seal Remove snap ring, retainer washer, spring and friction collar. Remove valve rod from piston rod.

2) Drive out piston retaining pin from piston (part way) and note if piston is free on piston rod. If piston is free on rod, hold spring compressed while removing retainer pin from piston. If piston is tight on rod after retaining pin removed, use a 5/8" diameter brass rod with squared end to drive piston rod out of piston

3) Separate piston rod, end plate and spring from piston, and remove rubber stop washer from piston rod. Remove bolts and lockwashers and separate mounting ring, seal retaining spring, washer, piston rod leather

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO "PISTON TYPE" POWER UNIT (Cont.)

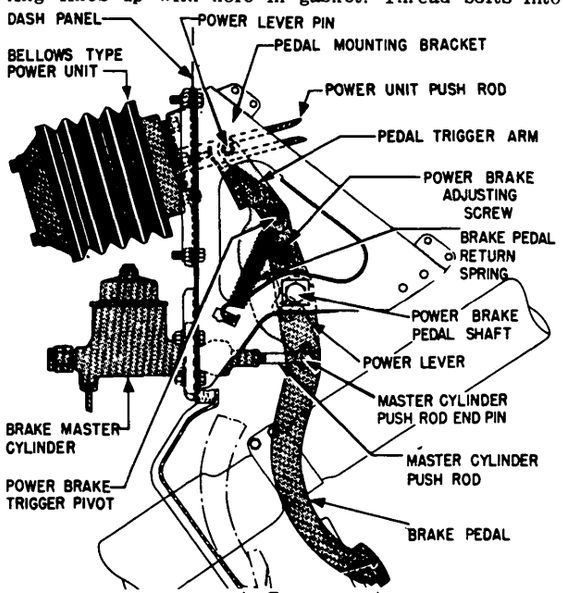
seal and mounting gasket from end plate. Take out screws and remove retainer plate, expander spring, wick, packing plate, and leather packing from piston plate.

REASSEMBLY: Wash all metal parts in Bendix Metaclene and all rubber parts in alcohol. Use air to blow out all passages. Inspect piston rod, valve seat at end of valve rod, or valve seat at center of piston plate and replace if scratched or nicked. Replace piston rod leather seal or piston leather packing if these parts worn excessively.

1) Assemble piston plate with threaded hole side up. Assemble leather packing on piston with lip side up. Place packing retainer plate on packing, with raised side up, and align holes in piston. Coil cotton wick inside of packing lip and cut wick to required length. Remove and dip wick in Bendix Vacuum Cylinder Oil. Let excess oil drip off, and again coil wicking inside lip of packing. Install expander ring inside of wicking, with gripper points next to wicking. Engage notch at loop end of spring with hook at opposite end of spring. Align holes in expander spring retainer plate with threaded holes in piston plate. Install screws.

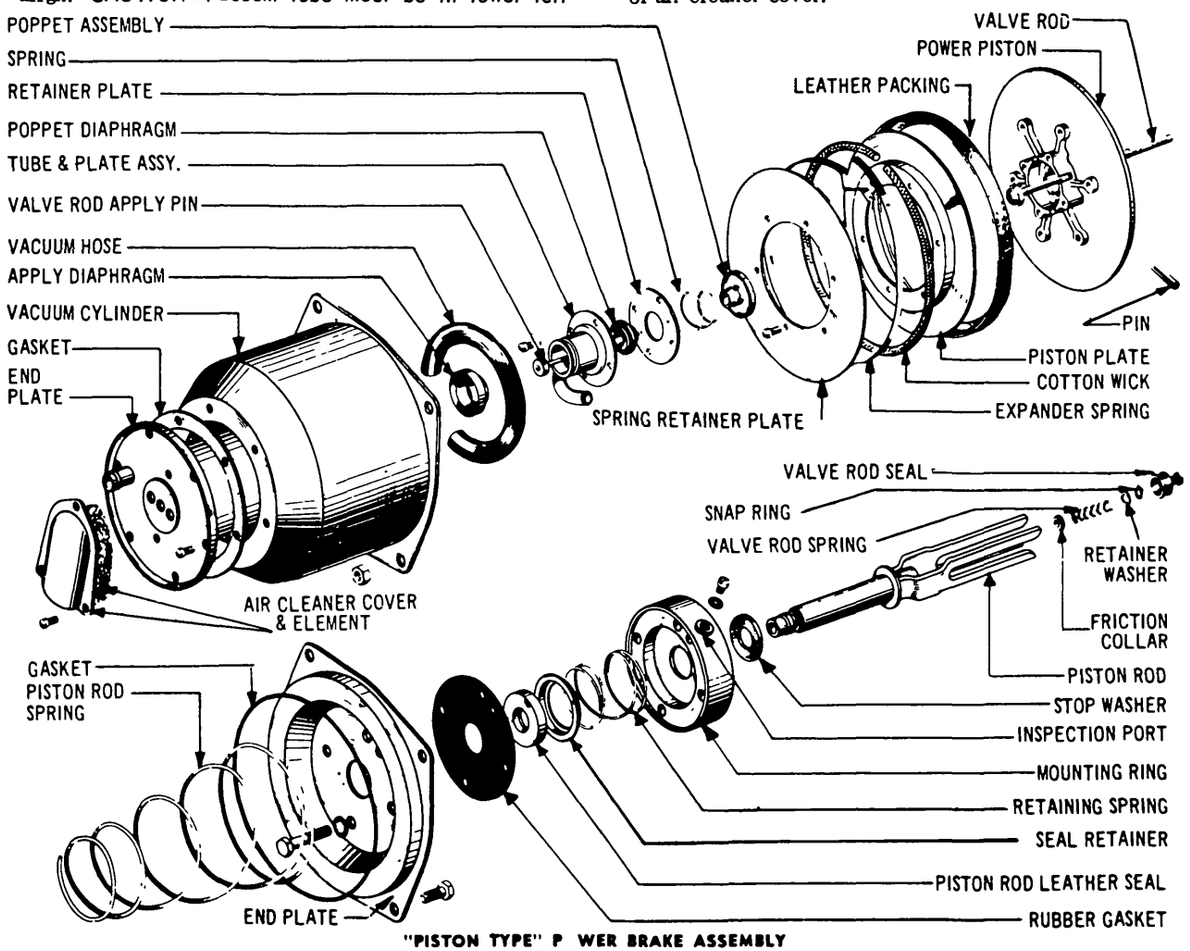
2) Install inspection port screw and gasket, if screw was removed. Insert bolts and lockwashers through holes in end plate and assemble mounting ring rubber gasket over bolts. *NOTE*–Align gasket inspection hole with holes in mounting ring and end plate.

3) Assemble new piston rod leather seal on gasket, with lip away from gasket, and center seal over hole in gasket. Place seal retainer over seal and install retaining spring. Coat bearing surface of mounting ring with silicone grease and assemble mounting ring on end plate, making certain inspection port hole in mounting ring lines up with hole in gasket. Thread bolts into mounting ring and tighten bolts.



4) Slide rubber stop washer over piston rod up against steel washer on piston rod and insert rod through seal in end plate. Assemble piston return spring on end plate with large diameter end next to plate. Align slot in piston rod and vacuum test port in end plate. Align piston so that two of four threaded bolt holes in valve side of piston are in line with slot in piston rod. Press piston on piston rod and install retaining pin.

5) Insert valve rod in piston until end of rod protrudes at opposite end of plate. Assemble friction collar, valve rod spring, and spring retainer washer over valve rod. Compress spring and install snap ring in groove in valve rod.



6) Assemble small diameter of poppet diaphragm in recess of poppet assembly. Assemble poppet spring over diaphragm with small diameter end next to poppet plate. Assemble retainer plate over large diameter of diameter of diaphragm and center poppet on piston plate. Align holes in retainer plate with holes in piston plate. Place vacuum tube and plate on retainer plate and align. *CAUTION–Vacuum tube must be in lower left quadrant. Ins rt when the slot in pushrod is horizontal and vacuum t st port is upward and approximat - ly 22½° to right of nd plat c nterline, r gardl ss of the scribe marks on tube plate and piston.*

7) Make certain that bead at outer diameter of diaphragm is in annular groove of tube and plate assembly. Replace tube and plate attaching screws and tighten securely and uniformly. Assemble valve rod applying diaphragm over end of tube and plate assembly. Slide vacuum hose on tube approximately 5/8", and coil hose so it is parallel to piston plate. Place new rubber gasket on end plate. Align vacuum cylinder and end plate to scribe marks. Install bolts and nuts (insert bolts through end plate and into cylinder flange) and tighten securely.

8) Place new gasket on end of vacuum cylinder. Align tube plate and vacuum cylinder scribe marks, and slide vacuum hose on vacuum tube approximately 5/8". Assemble four plate attaching screws. Align cleaner cover with tube plate and install screws. Tighten uniformly. Insert air cleaner material into opening at bottom of air cleaner cover.

POWER BRAKE PEDAL ADJUSTMENT

"PISTON TYPE" P WER BRAKE ASSEMBLY

DE SOTO, DODGE "OVAL PISTON" POWER UNIT

Chrysler Imperial (1959-60)
DeSoto, All Exc. S-26 Adv. (1957)
DeSoto (1958; 1959-60)
Dodge (1957-60)
Plymouth (1960)
NOTE - Chrysler, DeSoto, Dodge, Plymouth "Bellows" type also used.

►CHANGES, CAUTIONS, CORRECTIONS

►*1960 POWER BRAKE "THUMP" OR "THUD" (WHEN RELEASING BRAKE PEDAL) CORRECTION:* Remove brake pedal, then start engine so that piston rod and yoke will move out to expose rubber stop washer. Install an additional stop washer, Part No. 1675099, next to stop washer on piston rod by slipping new washer over piston rod yoke and into position on piston rod. Stop engine and depress power brake valve rod allowing rod and yoke to return to released position. Install brake pedal and reconnect master cylinder pushrod.

DESCRIPTION: Consists of an oval-shaped air-vacuum unit mounted on engine side of dash panel and connected mechanically to the brake pedal linkage through the power unit pushrod. A yoke at end of piston rod is in contact with the power lever pin of the reactionary linkage. The valve operating rod is located at the center of the piston rod and is always in contact with a ramp at the upper end of the valve trigger arm of pedal linkage. A control valve operating rod moves within the piston rod to actuate the vacuum valve and poppet. Mechanical contact between power unit and brake linkage exists only when power unit is assisting in a brake application. If vacuum fails, brake pedal is free to act independently to apply brakes in conventional manner. A vacuum reservoir, with check valve, is provided for a vacuum reserve.

OPERATION: Vacuum from the intake manifold, through the vacuum reservoir, is applied to unit, and air is evacuated from the applied direction side of the piston through the vacuum valve during brake application. When brakes are released, air (atmosphere) enters the unit through the built-in air cleaner and is regulated by the air valve. The valve operating rod, which is controlled by the pedal, and piston, is forced away from applied direction side by a return spring when brakes are released, permitting air to enter both vacuum and atmospheric chambers. Atmospheric pressure remains on both sides of piston until brakes are reapplied.

ADJUSTMENTS: Pedal Linkage Adjustment - If pedal pressure releases slowly, adjust by rotating adjustment screw (accessible through slot in left side of brake pedal bracket) **counter-clockwise.** A time delay (noted during a fast brake application) can usually be corrected by turning screw **clockwise.** Should pedal vibrate (booster chatter) turn screw in **counter-clockwise** direction. *NOTE* - Rotation of adjustment screw should be limited to plus or minus 90° from original setting.

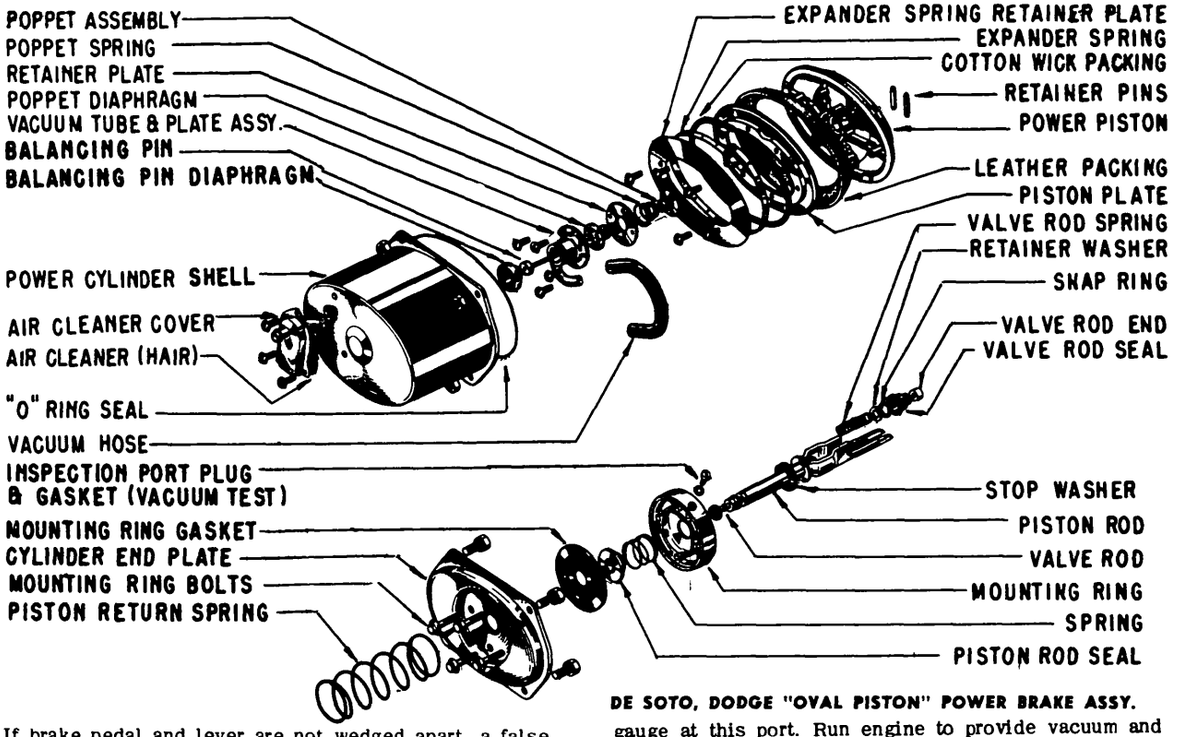
Pedal Free Play Adjustment: Remove vacuum hose and press brake pedal several times to release all vacuum. Insert blade of screwdriver between rubber collar of power brake trigger pivot and rear side of elongated hole in power brake lever, forcing them apart. (*NOTE* - If brake pedal and lever are not wedged apart, a false free play setting (which includes booster valve travel) will be measured at pad end of pedal). Check free play with linkage in this position by pushing lightly at pad end of brake pedal. Free play travel should be 1/32-1/8". If not within limits, adjust by lengthening or shortening pushrod as required.

Free Play Measurement (Alternate Method): Remove master cylinder pushrod end pin. With light finger pressure, move pushrod forward until contact made with master cylinder piston. Attempt to insert pushrod end pin through power lever and pushrod end hole. If pushrod must be pulled back to allow passage of pin, free play is present. If pushrod must be pushed further into master cylinder to allow passage of pin, no free play is present and adjustment must be made at pushrod.

LUBRICATION: Periodically place a few drops of SAE 10W Engine Oil on brake lever pin bushings. No other lubrication required

TROUBLE SHOOTING: Pedal Releases Slowly After Application or Brake Pedal Vibrates (Booster Chatter) - Pedal trigger arm improperly adjusted. *See Adjustments.* **Delay in Application (during Fast Brake Application)** - Pedal trigger arm improperly adjusted *See Adjustments.* **Lack of Power Assistance (When Cold):** (*NOTE* - This condition only occurs after long periods of disuse). To correct, disassemble, clean off all old lubricants. Soften seals and diaphragm with silicone grease.

TESTING (On the Car): Check brake operation on the car using engine vacuum. Remove screw plug from mounting ring, connect test fitting, hose, and vacuum gauge at this port. Run engine to provide vacuum and make test as follows:



1) With brakes released and engine idling, note vacuum gauge reading Gauge should read Zero indicating that brakes fully released. Reading of 1-16" indicates brakes not fully releasing. Check pedal adjustment. If pedal adjustment correct, power unit is faulty.

2) Depress brake pedal slowly and note vacuum gauge reading. Reading of 1-16" indicates power unit is operating. A zero reading indicates incorrect pedal operation, restriction in vacuum line, or faulty power unit. Check pedal adjustment. If pedal adjustment correct, remove power unit and disassemble for overhaul.

Checking Vacuum Source (Without Gauge): With engine stopped, depress brake pedal several times to exhaust vacuum in system and reserve tank. Start engine while holding pedal partially depressed. As soon as engine starts, pedal should move away from pressure being applied (indicating action of power boost). Shut off engine. Depress brake pedal 6-10 times noting effort required to press pedal in same distance each time. Effort required should increase from first to last application as vacuum source is depleted. If no difference noted in pedal effort with engine running or stopped, check for restriction in vacuum supply line by disconnecting line at power unit and holding finger over end of hose with engine running. A high vacuum should be noted.

REMOVAL & INSTALLATION: Power Unit - Place wood wedge between power brake lever and forward edge of triangular hole in pedal bracket to prevent trigger arm

CONTINUED ON NEXT PAGE

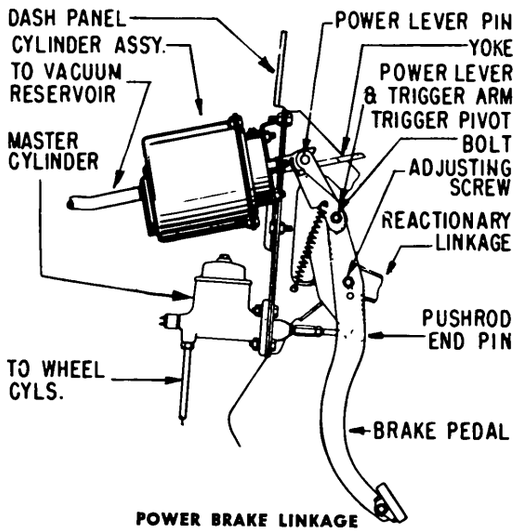
DE SOTO, DODGE "OVAL PISTON" POWER BRAKE ASSY.

DE SOTO, DODGE "OVAL PISTON" TYPE POWER UNIT (C nt.)

from extending beyond extremities of bracket. (*NOTE* - If pedal linkage is allowed to extend through hole in dash panel, damage to trigger arm may result). Disconnect vacuum nose at power unit. Remove attaching bolts at dash panel and carefully remove power unit assembly. (*NOTE* - Use care not to lose pedal linkage cross pin). To install, reverse removal procedure. Install unit on dash panel so its axis inclines down and toward front of car.

Pedal Linkage - Remove pedal return spring, master cylinder pushrod end pin and power brake pedal lever shaft. Rotate pedal linkage assembly counter-clockwise while withdrawing power lever cross pin from booster unit yoke. (*NOTE* - Pedal is slotted to provide clearance for removal of brake pedal assembly). To install, reverse removal procedure. (*CAUTION* - Use extreme care during assembly and handling of linkage. Trigger arm is easily damaged). If power brake unit has been removed, place a wooden wedge between power brake lever and forward edge of triangular hole in pedal bracket to prevent trigger arm from extending beyond extremeties of bracket.

OVERHAUL: Disassembly - Scribe mark across flange of power cylinder and end plate as a guide for reassembly. (*CAUTION* - Do not clamp yoke in vise at any time). Remove bolts mounting endplate on cylinder, separate endplate and "0" ring seal from cylinder shell, disconnect vacuum hose from fitting within cylinder. Take out air cleaner attaching screws, remove air cleaner and filter material from end of cylinder. Disconnect vacuum hose from fitting on tube and plate assembly. Separate and disassemble all sub-assemblies as follows:



Control Valve - Remove balancing pin diaphragm from end of plate assembly housing, withdraw balancing pin from housing (use long nosed pliers). Take out tube and housing attaching screws, separate housing from piston. Remove valve assembly. Remove valve retaining plate by compressing diaphragm and working plate off over diaphragm, remove spring, remove diaphragm from poppet valve by "peeling" it off. Remove nylon valve rod end button from valve rod (within yoke) by using a thin bladed screwdriver on a 1" x 1" wooden block as a pry. Slide valve rod seal off, remove snap ring retaining valve rod in piston, remove valve rod washer and spring, then slide valve rod out of piston.

Piston Rod - Drive out two piston rod retaining pins using a 3/16" drift (*CAUTION* - Do not allow return spring to snap piston off rod as pins are removed). Remove piston and return spring, then slide piston rod out of endplate and remove rubber stop washer from rod.

Endplate - Take out mounting ring attaching bolts and separate endplate from mounting ring. Remove seal retainer spring, piston rod leather seal and mounting ring gasket. Remove vacuum inspection port plug and gasket from mounting ring.

Pist n Plate - Take out screws mounting retainer plate on piston plate, separate these parts, remove expander spring, wick, packing plate, and leather packing.

Cleaning & Insp ction: Clean all rubber parts in alcohol.

POWER BRAKE LINKAGE

Thoroughly wash all metal parts. If inspection reveals nicks or scratches on piston rod, valve seat end of valve rod, or valve seat at center of piston plate, replace parts. Replace an excessively worn leather packing or piston rod leatner seal. If vacuum cylinder is rusted or corroded, polish with fine steel wool or crocus cloth.

Reassembly: Use all new gaskets. Lubricate parts with oil or silicone grease as noted below.

Piston Plate Assembly - *NOTE* - Installation will be facilitated by using Tool C-3578 to install packing parts on piston. Proceed as follows: Place piston in assembly tool with threaded holes in piston upward, install leather packing on piston with lip side up, place packing retainer plate on packing with the raised side up and align holes in plate with holes in piston. Coil cotton wick inside packing lip and cut to required length. Remove wick and dip in vacuum cylinder oil, allow excess oil to drip off, then install packing on piston. Install expander spring inside wick (with gripper points next to wicking) and engage notch at loop end of spring with hook at opposite end. Install expander spring retainer plate and align holes in plate with threaded holes in piston plate, install screws and tighten securely. *Leave piston assembly in tool until it is installed in vacuum cylinder.*

Mounting Ring & Endplate Assembly - Install vacuum inspection port screw and gasket in side of mounting ring. Insert ring retaining bolts through holes in endplate, apply silicone grease to outer face of gasket around center hole, install gasket on endplate bolts (*CAUTION* - Vacuum port opening in gasket must be aligned with opening in endplate). Install piston rod leather seal on gasket with raised shoulder up, slide spring over shoulder and seat spring against seal with both parts centered on gasket. Coat bearing surface of mounting ring with silicone grease, slide mounting ring down over mounting bolts with recessed side down and vacuum port holes aligned, tighten bolts securely. *NOTE* - Outer rim of mounting ring should contact endplate.

Pist n R d - Install rubber stop on the piston rod and against the steel washer. Install Pilot Tool C-3579 on end of piston rod (*NOTE* - If pilot not used, wrap approximately 1¼" of piston rod with scotch tape to prevent sharp edges of rod damaging seal). Insert piston rod through endplate, remove pilot tool or tape, install piston spring over piston rod so that it is seated against endplate, install piston assembly on rod and seat it against shoulder on rod, install two retaining pins in holes in piston boss (*CAUTION* - Hold rod seated against piston while installing pins).

Valve Rod Assembly - Insert valve rod through piston and piston rod, install spring and retainer-washer on end of rod, compress spring and install snap ring in rod groove. Install valve rod seal on valve rod and piston rod (*NOTE* - To aid in seal installation, turn seal partially inside out and install small diameter over valve rod first, then slide large diameter over piston rod). Install nylon button on end of valve rod and press on until seated.

Control Valve Assembly - Assemble valve diaphragm on valve (small diameter of diaphragm on small diameter of valve), install valve spring over diaphragm (small diameter against valve), install retainer plate over large end of diaphragm (*CAUTION* - Keep assembly compressed to prevent spring separating diaphragm from valve). Install assembly on piston, place vacuum tube assembly in position on retainer plate (*CAUTION* - Bead on diaphragm must be in annular groove of housing and screw holes must be aligned), make certain that scribed marks are aligned, tighten attaching screws securely. Install balancing pin and diaphragm in end of vacuum tube assembly, slide vacuum hose over housing tube.

Final Assembly - Install air cleaner housing on end of cylinder and tighten attaching screws securely. Slide new "0" ring seal over piston and position on shoulder of endplate. Remove assembly tool C-3578 from piston, position piston assembly in front of cylinder, connect vacuum hose to air cleaner tube within cylinder. Slide piston into cylinder and install endplate, tighten bolts securely. Pack air cleaner housing with filter hair. Test brake assembly as follows:

TESTING (Brake Assembly after Overhaul): Operati n Test - Connect vacuum source to vacuum tube at air cleaner end of cylinder, apply vacuum of 15-20". Piston and yoke should move to fully extended or applied position (if valve not depressed). Piston should move throughout full stroke without hesitation. *CAUTION - Piston will move out to end of stroke without restriction in above test (with no force applied to end of valve operating rod) and unit should only be tested wh n fully assembled.*

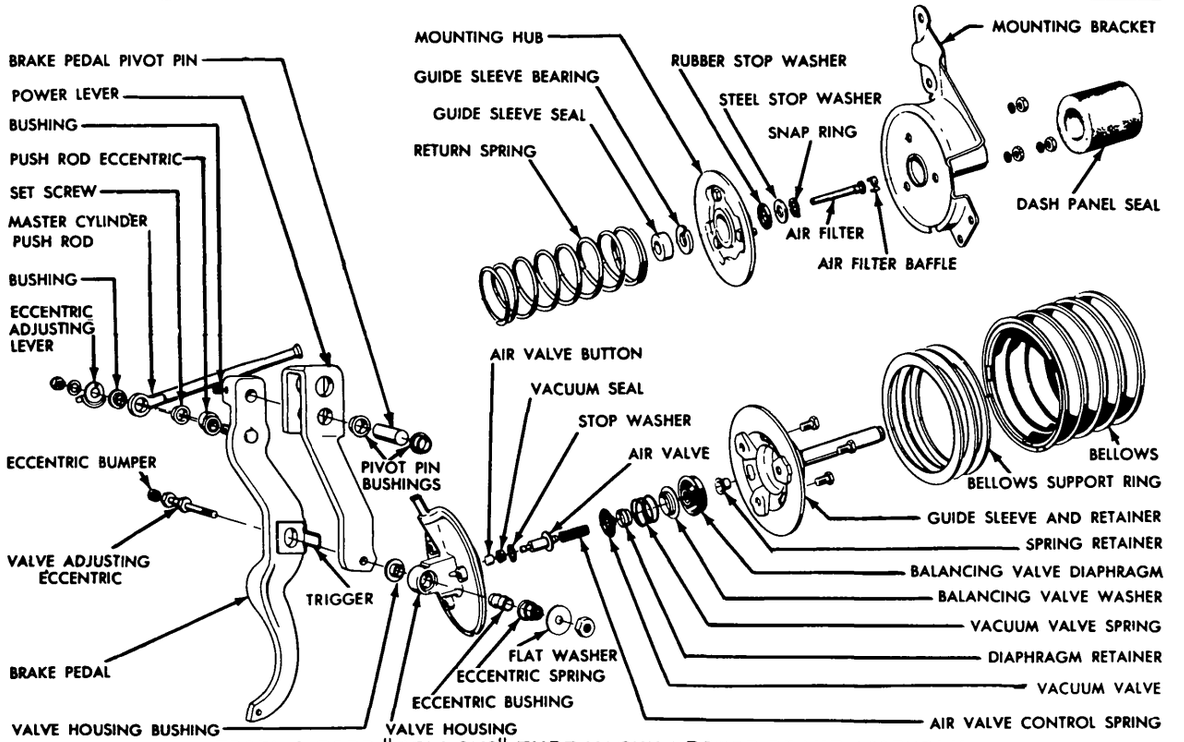
Leakage Test - Use a vacuum gauge and shutoff valve in the vacuum line near the brake power unit. Press in on valve operating rod, apply 15-20" of vacuum to power cylinder, close shutoff valve. Vacuum leakage (gauge drop) should not exceed ½" in 60 seconds. Open vacuum shutoff valve, release valve operating rod and allow piston to move to the end of its stroke. Close shutoff valve and check leakage which should not exceed 1" in 10 seconds.

EDSEL & FORD "BELLOWS TYPE" POWER UNIT

Edsel 6 Cyl. (Early 1959, 1960) Ⓒ
F rd Pass. Cars Exc. Thunderbird (1957)
Ford Pass. Cars & Thund rbird (1958, Early 1959, 1960) Ⓒ

Ⓒ - Bendix Power Unit "Hydraulic (Disc) Reaction Type" also used.

DESCRIPTION: The "Pedal-Assist Power Unit" consists of an air-vacuum bellows and control valves, with vacuum supplied from engine intake manifold, and vacuum reserve tank. Unit is mounted on driver's side of dash panel and attached to brake power lever. Brake power lever is linked to brake pedal. Brake pedal position controls closing of air valve and opening of vacuum valve. Master cylinder is mounted on engine side of dash panel, and is operated by master cylinder pushrod directly connected to brake pedal.



OPERATION: Bellows chamber is open to atmospheric pressure when pedal in released position. As pedal is depressed, finger on pedal contacts air valve causing it to close at the same time opening the vacuum valve. Intake manifold vacuum (or reserve tank vacuum) moves air from bellows chamber. As pressure decreased, bellows contracts and exerts a force on the brake power lever, which is transmitted through the connecting link to the brake pedal and assists the operator in depressing the pedal. When pedal is held in a fixed applied position the assist pressure is held constant. Assist pressure is directly in proportion to pedal apply pressure. As pedal is released, air valve is opened by spring pressure, admitting atmospheric pressure to bellows chamber so bellows expands to normal position.

ADJUSTMENTS: Air Valv - Turn valve-adjusting eccentric until unit chatters when pedal is depressed, then turn eccentric until chatter disappears. (*CAUTION* - Do not turn eccentric more than necessary or "cut-in" will be excessively high). *NOTE* - If satisfactory adjustment of eccentric cannot be made, look for bent pedal trigger. Pedal trigger is bent when distance from back of trigger to front edge of hole in pedal is less or greater than .950"±.005". To correct, bend trigger or replace pedal. Tighten nut to 180-220 inch lbs.

Mast r Cylind r Pushr d - Loosen pushrod eccentric locknut. Rotate eccentric clockwise to maximum to shorten pushrod so master cylinder piston will return to fully unapplied position. Rotate eccentric counterclockwise until master cylinder piston starts to resist movement of pushrod. Hold eccentric and tighten locknut to 180-220 inch lbs. Bubble or spurt at compensator port in master cylinder indicates pushrod properly adjusted.

REMOVAL: P w r Unit - Remove vacuum hose from top of unit. Remove valve adjusting eccentric with flat washer, spring, and bushing. Remove nylon bushing from power unit valve housing. Remove two mounting bracket-to-dash panel screws and remove power unit from car.

Brak P dal - (Cars with clutch pedal). Release clutch release assist spring tension at adjuster, remove spring, idler lever from clutch pedal lever. Remove clutch shaft retaining clip, spring washer, and flatwasher, clutch pedal and shaft from support bracket. **(Cars without clutch).** Remove brake pedal shaft, support brake pedal and power lever, and remove pedal bushing. Leave master cylinder pushrod attached to brake pedal. Pull master cylinder pushrod out of master cylinder boot. *NOTE* - Replace pedal pivot bushings as necessary. Remove pedal pivot pin set screw, drive out pivot pin, remove power lever. Lubricate new nylon bushings with silicone lubricant, reassemble power lever, install pivot pin and set screw, replace brake pedal and power lever in car.

EDSEL & FORD "BELLOWS" TYPE VACUUM POWER BRAKE ASSEMBLY

INSPECTION: Wash all metal parts including air filter in alcohol or solvent which will not leave oil film, and dry all parts with moisture-free compressed air. Wash rubber parts in mild soap and water, rinse clean and dry with air. Replace worn or damaged parts, including valve housing if vacuum valve seat is damaged.

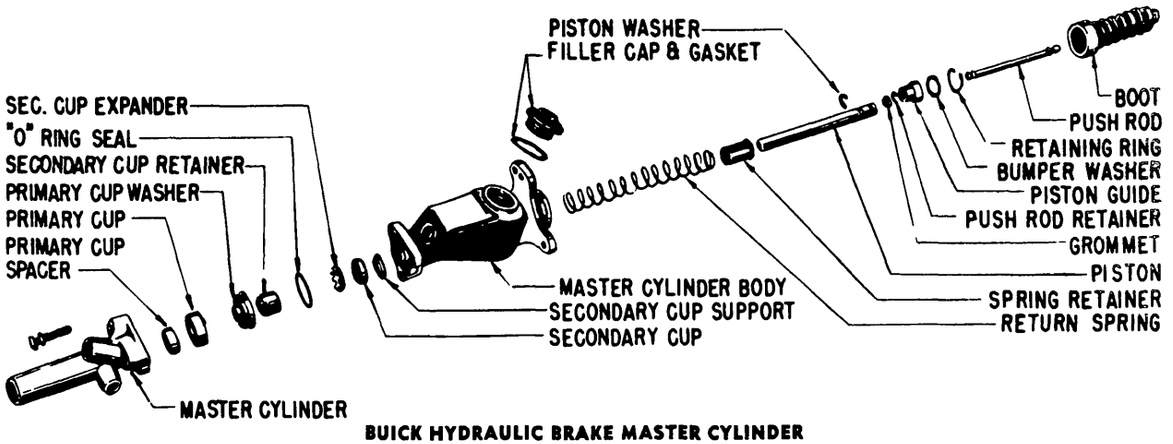
REASSEMBLY: Mount valve housing in vise with alignment marks visible. To install air and vacuum valves, reverse disassembly procedure after lubricating parts with silicone lubricant. *NOTE* - Retainer is installed on valve balancing diaphragm with small diameter toward the diaphragm, and the retainer and center diaphragm must be pressed down over the vacuum valve neck. Use three support rings when replacing bellows. Assemble bellows (either end) over retainer and guide sleeve assembly, with three bosses in retainer aligned with three slots in bellows. Place bellows and retainer over valve balancing diaphragm and in position on valve housing. Finger tighten three capscrews, then tighten to 85-115 inch pounds. *CAUTION* - Sight down guide sleeve to insure air valve control spring is seated squarely in retainer. Test air valve by pressing it in gradually and noting the increased spring tension from air valve spring to vacuum valve spring. Valve should snap back readily. Place return spring on guide sleeve, slide mounting hub on sleeve, hold down against return spring and assemble bellows over mounting hub. Hold mounting hub down, install rubber stop washer, steel stop washer over guide sleeve, then snap ring. Install air filter baffle on filter, filter and baffle in guide sleeve. Filter baffle fits in same groove with and above snap ring. Place mounting bracket on mounting hub, align notch in mounting bracket with tab on bellows, install lockwashers and nuts and tighten to 85-115

CONTINUED ON NEXT PAGE

EDSEL & FORD "BELLOWS TYPE" POWER UNIT (Cont.)

inch lbs. Install dash panel seal. Install nylon bushing in valve housing.

INSTALLATION: Pull brake pedal back until master cylinder pushrod hangs free. Position power mounting bracket on dash panel, with brake pedal finger in position against air valve button and tighten nuts and screws. Install valve-adjusting eccentric and bumper through brake pedal and valve housing of power unit. Slide eccentric bushing (either end) over valve-adjusting eccentric and into valve housing. Install eccentric spring with large coils toward housing, then flatwasher and nut. Tighten valve eccentric nut until eccentric bolt is firmly locked to power lever but can still be turned for adjustment. Adjust eccentric, *see Adjustments preceding.* Disconnect mounting bracket from dash. Pull power unit and pedal back toward car seat until master cylinder pushrod can be inserted in master cylinder boot. Reattach mounting bracket to dash panel. Adjust master cylinder pushrod, *see Adjustments preceding.*



BUICK HYDRAULIC BRAKE MASTER CYLINDER

Buick, All Models (1956)

DESCRIPTION: This new master cylinder is a displacement type and is connected directly to the brake pedal by a pushrod. Pedal linkage adjustment is not required. The hydraulic check valve has been removed from the master cylinder to the junction block which is located inside of the front center cross member just behind the pitman shaft. The stop light switch is located on the left side of the master cylinder.

OPERATION: The operation of the displacement type master cylinder is similar to conventional master cylinders except that the piston travel is longer (4"), and the hydraulic brake fluid check valve is located in the brake line junction block. Fluid replenishment is provided in the usual manner from the master cylinder reservoir, which is integral with the master cylinder.

REMOVAL: Disconnect brake pipe from master cylinder and tape end of pipe to prevent entrance of dirt. Disconnect stop light wires from stop light switch and disconnect pushrod from brake pedal. Remove brake pedal Remove screws holding steering column jacket rubber seal retainer to firewall and push it up on steering column jacket Pull floor mat away from toe pan and remove the toe pan Remove master cylinder attaching bolts and remove master cylinder

BUICK HYDRAULIC BRAKE MASTER CYLINDER

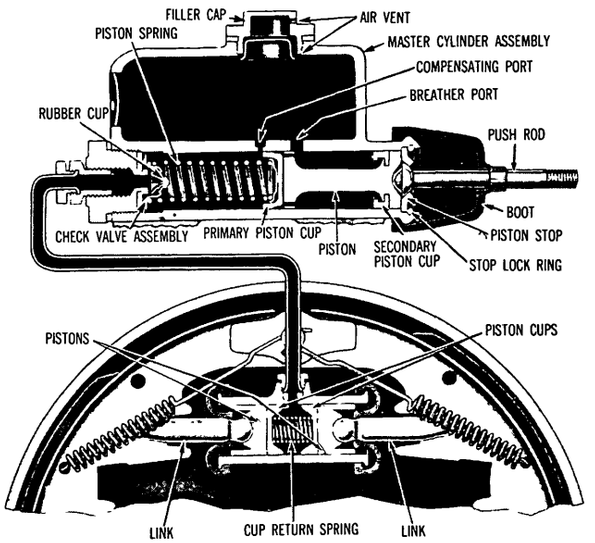
DISASSEMBLY: Remove toe pan from master cylinder (if car is equipped with synchro-mesh transmission, remove heat shield). Clean outside of master cylinder, remove filler cap and drain hydraulic fluid from reservoir. Place master cylinder in vise in vertical position with pushrod up. Remove boot from pushrod and using Truarc Ring Pliers, J-4245, remove retaining ring and guide bumper washer. Remove pushrod and piston from body. Remove return spring, retainer and piston washer. To disassemble pushrod from piston, insert piston into a 9/16" I.D. washer and support washer on jaws of vise *(CAUTION–Protect piston with a cloth. Do not clamp piston in vise).* Hold piston and strike the pushrod with a soft mallet to drive piston out of guide. Remove grommet and pushrod retainer from end of pushrod. Turn cylinder with opposite end up and remove the bolts holding cylinder to body. Remove primary cup insert, cup, and spacer from cylinder. Remove primary cup washer, "O" ring, bearing, secondary cup retainer, expander, cup and cup support from assembly body. Discard primary cup, washer, "O" ring, *bearing, secondary cup, expander, piston guide,* grommet, retaining ring, boot, and filler cap gasket.

INSPECTION: Wash all parts in "Declene" or a good grade of clean alcohol *(CAUTION–*Do not use gasoline, kerosene or mineral base oil) Inspect all parts and replace any that are defective Inspect pushrod bore and counterbore for pits, scoring, rust or dirt. Make sure that bore from reservoir to cylinder bore is clean and open *NOTE–*Bores of master cylinder body and nose piece may be cleaned and reconditioned with fine crocus cloth if not too deeply scratched The piston is chrome plated and sand paper or emery cloth should never be used on its surface

REASSEMBLY: Place piston guide on pushrod and move to a position so that pushrod retainer and grommet can be installed on end of pushrod. Install piston guide on piston so that land of piston guide engages groove of piston. Install piston washer, spring retainer, and return spring on piston. Place pushrod and piston assembly in body and insert guide bumper washer and retaining ring. Replace boot on pushrod and turn cylinder so opposite end is up. Place secondary cup support, cup, expander, retainer, bearing, "O" ring, primary cup washer and insert in body assembly. Install primary cup spacer and primary cup in hydraulic cylinder Bolt hydraulic cylinder to body and check filler cap vent holes to make sure they are clean, then install cap nut and gasket

INSTALLATION: Reverse removal procedure, and bleed brake system

HYDRAULIC BRAKE TROUBLE SHOOTING



Inspecti n & Testing: Inspect brakes at frequent intervals for pedal reserve (clearance between pedal pad and toeboard, when pedal firmly depressed, while brakes are cold). Increase pedal reserve by adjusting brake shoe to drum clearance. Brakes should be tested on dry, clean, reasonably smooth level roadway (not with wheels jacked up). Test at different speeds both with light and heavy pressure. *CAUTION - DO NOT l ck wh ls and slid tir s on roadway.*

Ext mal Conditi ns That Affect Brake Performance: 1) Right and left tires must be of same size with approximately the same non-skid tread pattern.
2) Car must be loaded equally as heavily loaded wheels require more braking power.
3) Loose front wheel bearings permit drum to tilt causing spotty contact with linings and erratic brake action
4) Misalignment of front end (particularly camber and kingpin inclination) will result in unequal action between wheels.
5) Faulty shock absorbers permit car to bounce on quick stop and will give the impression that brakes are too severe.

INDICATION & CORRECTION: Pedal Travel Excessive r G s t T board - 1) Excessive Brake Shoe Clearanc . Adjust brakes to specified clearance.
2) Low Fluid L v l in Reservoir. Fill reservoir and check for springy pedal action.
3) Air in Hydraulic Syst m. Bleed hydraulic system.
4) Fluid L ak in Hydraulic System. Check for external leaks, if none found, check all wheel cylinders for evidence of fluid loss. When neither of above conditions exist, remove master cylinder and inspect for internal leak. Check Power Brake Cylinder for scores or other damage to hydraulic plunger or rubber cups.
5) Impr per Brak Fluid. Flush system and refill with specified type of fluid.

Springy, Spongy Acti n f Brake Pedal: 1) Air in Hydraulic Syst m, Insufficient fluid in reservoir, disconnected or loose line, clogged filler cap vent, or leaky check valve. Correct above conditions, bleed lines and refill reservoir.
2) Brak Sh s Not Properly Adjusted. Adjust brake shoes to specifications (especially anchor pin).
3) Out-of-R und Brak Drum. True up drum as necessary.

Brak s Sev r on Light P dal Pressure: 1) Loose Front Wheel B arings. Check and adjust as necessary.
2) Lo s Brak Backing Plate. Tighten all backing plate bolts and adjust anchor pins to centralize shoes.
3) Excessiv Dust in Brake Assembly. Thoroughly clean brake shoe linings to remove embedded dirt.
4) Faulty Brak Sh Linings or Drums. Charred linings or scored drums. Grease or brake fluid on linings (will cause grabbing action). Replace linings and true up or replace scored drums.
5) Brak Sh Lining R v rsed. Primary and secondary linings reversed. Install brake shoes in proper position.

HYDRAULIC BRAKE SYSTEM (SCHEMATIC)

Excessive Pedal Pressure Required: 1) Brake Shoe Not Properly Adjusted. Adjust anchor pins and brake shoes.
2) Foreign Substance on Brake Lining. Replace grease or fluid soaked linings. Sand off other foreign substance.
3) Improper Brake Lining. Install standard lining.
4) Improper Brake Fluid. Replace rubber cups, flush system and refill with specified brake fluid.

Hard, or Sticky Initial Pedal Pressure on Power Brakes: 1) Binding in Pedal Linkage. Remove and lubriplate linkage pivot pins.
2) **Swollen Hydraulic Cups.** Replace all rubber parts and completely flush system to remove all traces of mineral oil.

Power Brake Cylinder Does Not Boost: 1) Test For Power Cylinder Operation. Stop engine, apply pedal pressure several times to remove all vacuum from system. Hold pressure on pedal, start engine. Pedal will move slightly forward when cylinder is operating.

2) Power Cylinder Does Not Operate. Check following items: A) Vacuum Check Valve stuck closed. Free up or replace valve. B) Vacuum Pipe Bent, Broken or Obstructed. Replace any damaged or plugged parts and make sure all connections are tight. C) Blocked Air Inlet. Clean or replace parts as required. D) Air Valve Sticking in Power Piston. Remove and disassemble power cylinder for inspection.

3) Power Cylinder Operates But Braking Action Not Normal. Check the following items: A) Insufficient Brake Fluid in System. Fill reservoir, bleed all lines and check for leaks. B) Brake Lining Condition. Check for glazed, dirty, or oily brake linings. Clean or replace.

Brak s Drag At One Wheel: 1) Loose Front Wheel Bearings. Check for play in bearings with wheel jacked up and adjust if necessary.
2) Insuf ficent Clearance at Brake Shoes. Adjust brake shoes.
3) Weak or Broken Brake Shoe Spring. Replace spring and make brake shoe adjustment.
4) Wheel Cylinder Piston Stuck or Cups Distorted. Overhaul wheel cylinder and replace damaged or defective parts.
5) Obstruction in Brake Pipes or Hoses. Flush hydraulic system or replace damaged or defective parts as required.

Brakes Drag at All Wheels: 1) Insufficient clearance at brake shoes. Adjust as necessary.
2) Master Cylinder Compensating Holes Closed. Make certain that pedal is free on pivot and at pushrod connection. When freeing up pedal does not correct condition, remove master cylinder for disassembly and thorough cleaning. *CAUTION* - Never insert test wire through compensating holes as wire will leave burr and cause damage to primary cup.
3) Wheel Cylinder Cups Distorted. When rubber parts of master cylinder are swollen or distorted, all wheel cylinder rubber parts will also be affected. Thoroughly flush the entire system and replace all rubber parts.

Power Brakes Do Not Release Properly: *NOTE - S "Brakes Drag At All Wheels" above for causes not caused by power brake cylinder and its linkage.*
1) Binding Pushrod. See item (1) under "Hard or Sticky Initial Pressure on Power Brakes" above.
2) Swollen Hydraulic Cups. See item (2) under "Hard or Sticky Initial Pressure on Power Brakes" above.
3) Plugged Compensating Ports. Remove and disassemble power cylinder, clean thoroughly and flush brake hydraulic system to remove all dirt.
4) Power Unit Internal Friction. Remove, disassemble, and inspect power cylinder, for weak or broken springs and for dry rubber cups and O-ring seals. Reassemble as specified.

Car Pull to One Side: 1) Tires Unequal. Rearrange tires so tread non-skid characteristics are more nearly equal on both sides of car.
2) Brake Shoes Improperly Set, Adjust anchor pins and brake shoes.
3) Loose Front Wheel Bearings. Check play in bearings with wheels jacked up and adjust if necessary.
4) Out-of-Round or Scored Brake Drums. True up or replace as required.
5) Brake Linings Not Matched or Improperly Placed. Replace or change linings as required.
6) Foreign Substances on Some Brake Linings. Thoroughly clean any linings having water, sand, paint, imbedded particles of metal, etc. on surface. Sand and brush affected surface - DO NOT use any liquid cleaning agent. Replace linings that have oil, grease or hydraulic fluid on them as they cannot be cleaned satisfactorily.

CONTINUED ON NEXT PAGE

HYDRAULIC BRAKE TROUBLE SHOOTING (Cont.)

Brakes Squeak: 1) Brake Shoes Not Properly Adjusted. Make uniform clearance adjustment and anchor location, 2) Brake Drum Condition. Rebore any drum that is out-of-round or scored. Replace any drum that is cracked or has hard spots in braking surface.
3) Foreign Material Imbedded in Surface. Clean surfaces of lining and remove all particles of metal. If necessary use portable resurfacing machine to properly clean surfaces and to insure good drum contact.
4) Linings Loose on Brake Shoes. Re-rivet linings to shoes.
5) Bent Brake Backing Plate. True up or replace backing plate.
6) Improper Brake Shoe Lining. Install standard recommended lining.
7) Shoes Scraping on Backing Plate. Clean, smooth up, and lubricate surfaces and reduce shoe movement by adjusting to safe minimum clearance.

Brakes Fade (Fail to Hold): "Fade" is caused by loss of friction due to heat cooking out most volatile ingredients of bonding material in lining that acts as a lubricant. Loss of ingredients through heat affect lining efficiency. Improperly compounded linings will also cause fading. When brake drums have been rebored too thin they will expand under high temperatures causing fade. Replace linings and/or drums as necessary.

SERVICING NOTE: *See following article for directions for bleeding lines and servicing master and wheel cylinders. See separate brake data pages for brake shoe and brake pedal adjustment directions.*

HUDSON MECHANICAL FOLLOW-UP

Hudson, All Models Except Jet (1954-57)

DESCRIPTION & OPERATION: Consists of over-running mechanical linkage between brake pedal and hand lever equalizer bar plate or hand brake bellcrank, by which wheel brakes are set mechanically through hand lever linkage after movement of pedal is sufficient to operate brakes hydraulically. Acts as a reserve if hydraulic application fails or when pedal travel is excessive.

ADJUSTMENT: Adjust models as follows:

1954 Models - With the brakes in fully released position loosen locknut on threaded follow-up rod below brake pedal, and turn adjusting nut until clearance between rear side of brake pull rod slide link retainer pin and rear end of slot in slide link is 1¼", tighten locknut.

1955-57 Models - Disconnect cable from brake pedal and master cylinder piston pushrod from brake pedal. Place a 3½" spacer block between brake pedal rod pad and floor mat. Depress pedal rod until pad contacts spacer block; retain in that position and adjust mechanical follow-up cable length at clevis end so that clevis pin can be installed freely with no slack in cable.

HYDRAULIC BRAKE SERVICING

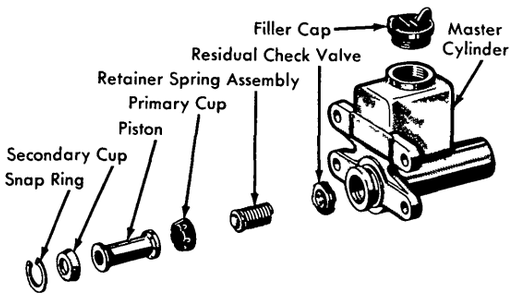
BLEEDING BRAKE LINES: Bleed hydraulic system at all four wheel cylinders if air has been introduced through low fluid level or by disconnecting brake pipe at master cylinder. When pipe at only one wheel cylinder has been disconnected, only that wheel cylinder needs bleeding. If a pipe has been disconnected at any fitting between master and wheel cylinders, then all wheel cylinders serviced by that pipe require bleeding. The system should be bled in the following sequence:
1) Master Cylinder (when equipped with bleeder fitting).
2) Power Unit (when so equipped).
3) Rear wheel farthest from master cylinder, except as follows: Buick, Pontiac and Valiant, bleed cylinders in following sequence, Left Front, Right Front, Left Rear, Right Rear. When car equipped with 2 front wheel cylinders (per wheel) bleed lower cylinder first, then upper cylinder. Bleeding operations can be made with either a Pressure Tank or Manually.

►*PRESSURE TANK CAUTIONS:* To safeguard against air entering system, avoid the following: 1) Do not shake or agitate pressure tank after air pressure has been added. 2) Do not move pressure tank position, bring air line to tank when Additional air pressure is necessary. 3) Be sure that valves on pressure tank lines are not defective and allowing air to be sucked in when fluid passes through lines. 4) Keep pressure tank at least 1/3 full of fluid at all times. 5) When pressure tank is full of air bubbles, release air pressure so bubbles can escape and refill with pressure.

Pressure Tank Bleeding: Clean master cylinder cap and surrounding area, then remove cap. With pressure tank more than 1/3 full and with hose and master cylinder both filled with specified fluid, attach hose to master cylinder filler opening. Attach bleeder valve hose to wheel cylinder bleeder valve (early models, hose screws into bleeder valve, later models, other end of hose slips over bleeder valve. Place other end of hose in clean glass jar and unscrew bleeder valve 3/4 to 1 turn. Open pressure tank hose valve to supply fluid under pressure (not to exceed 35 lbs.). When fluid flowing from wheel cylinder bleeder valve into glass jar is free of air bubbles, close bleeder valve securely and proceed with bleeding other wheel cylinders in same manner.

Manual Bleeding: Fill master cylinder, install bleeder hose and glass jar to wheel cylinder as in pressure bleeding. Unscrew bleeder valve 3/4 to 1 turn. Depress brake pedal a full stroke, then allow pedal to return to released position. *CAUTION - Should pedal return quickly, air will be drawn into system.* Repeat this operation until fluid flowing from bleeder valve into glass jar is free of air bubbles, then close bleeder valve and proceed to other wheel cylinders as in pressure bleeding. *NOTE - Check level of fluid in master cylinder frequently during bleeding operation to insure that air will not enter system.* Refill master cylinder to proper level.

SERVICING: Wheel Cylinders - Removal & Disassembly - Remove wheel, drum, and brake shoes. DO NOT get grease or dirt on brake linings. Disconnect brake hose or pipe from wheel cylinder and cover opening with tape. On Chrysler Corp. Cars, remove support plate and wheel cylinder to backing plate nuts and washers. Slide support plate out of way, then remove wheel cylinder to support plate bolts and lift wheel cylinder from plate. On Other Cars, remove wheel cylinder from backing plate. Remove links, boots, pistons, cups, cup expanders and spring from cylinder.



Cleaning & Inspection - Discard rubber boots, expander assembly, and piston cups. Clean all other parts with hydraulic brake fluid or a good grade of alcohol. *CAUTION - DO NOT USE antifreeze alcohol, gasoline, kerosene, or any other cleaning fluid that might contain mineral oil.* Check piston and bores for scores, scratches or corrosion. Use crocus cloth to clean up light scratches or signs of corrosion (Chrysler Corp. Cars) or crocus cloth for light scratches, steel wool and alcohol for corrosion (Other Cars). Follow manufacturers recommendations regarding limited honing to clean up minor scratches.

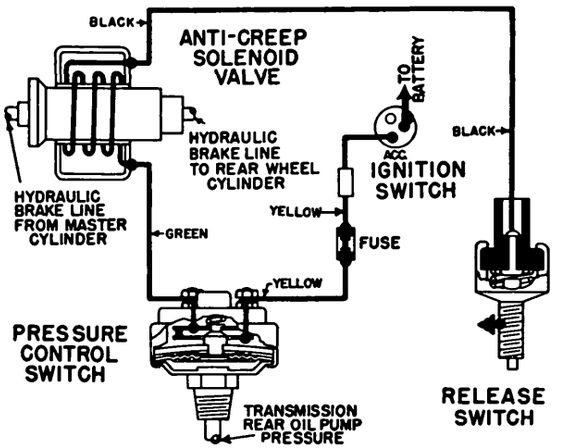
Reassembly - Reverse disassembly procedure, dipping pistons and cups in specified brake fluid as they are assembled.

Master Cylinder: Removal - *See Car Model Pages.*

Disassembly, Cleaning & Inspection - Clean outside of master cylinder, drain all brake fluid and disassemble. Replace scored or corroded piston and all piston cups. Follow same procedure for master cylinder as described for wheel cylinder in regard to use of crocus cloth, steel wool, alcohol, honing and use of other than alcohol cleaning solutions.

Reassembly - Reverse disassembly procedure and dip all parts in specified brake fluid, as they are assembled. *CAUTION - Compensating port in cylinder must be clear, but DO NOT run wire through port as it will form burr which will damage primary cup.* Recheck Pedal Freeplay when piston does not clear port. Follow manufacturers recommendations for clearances.

BRAKE MASTER CYLINDER (TYPICAL)



ANTI-CREEP

Stud bak r 1954-55 Models with Aut . Trans.

DESCRIPTION: System comprises a solenoid valve, pressure control switch and a release switch. With ignition on, or when engine idling and car is not in motion and brakes are applied, the rear brakes will remain on, after releasing brake pedal, until accelerator is again depressed. With car in motion, system is inoperative and brakes function normally.

OPERATION: The solenoid valve mounted on rear of master cylinder holds brake pressure on the rear brakes whenever the Anti-Creep circuit is closed. The pressure control switch which is operated by automatic transmission rear pump pressure, opens the Anti-Creep circuit when the car is moving forward, and closes the circuit when the car is stationary, or moving in reverse. The release switch opens or closes the circuit as the accelerator is depressed or released. With the ignition "on", the accelerator released (release switch closed), and the car stationary (pressure control switch closed), the Anti-creep circuit is completed through these switches and the solenoid valve is energized. When the brakes are applied under these conditions, the anti-creep solenoid valve will retain approximately 200 pounds per square inch pressure at the rear wheel brakes to prevent "creeping." When the accelerator pedal is depressed, the circuit is open at the idle adjusting screw switch allowing the solenoid to de-energize thereby releasing the brakes instantly. When the car is moving forward, normal brake operation is not affected since the rear pump pressure holds open the Anti-Creep pressure control switch, preventing solenoid from energizing.

CONTROL UNITS REMOVAL & INSTALLATION: If

ANTI-CREEP CONTROL WIRING DIAGRAM

operation not satisfactory and checking indicates units defective, remove and replace as follows:

Release Switch: To remove switch, disconnect switch lead, loosen locknut and unscrew switch from bracket.

Pressure Control Switch—To remove, disconnect switch leads, unscrew switch from transmission case.

Solenoid Valve: To remove, disconnect all leads, disconnect brake line at solenoid valve outlet. Take out screw mounting solenoid valve on adapter, lift unit out. Install solenoid valve in same manner.

►***CAUTION—Bleed brakes after installing solenoid valve and connecting brake line.***

ADJUSTMENT: Release switch is only point requiring adjustment. Adjust switch, for each model, as follows:

Champion - After transmission linkage adjustment is completed, loosen switch locknut and screw switch into bracket until switch plunger just contacts plate. Connect switch wire, turn on ignition, screw switch in until an audible click is heard in the anti-creep solenoid. Tighten switch locknut.

Commander & President - After carburetor and transmission linkage adjustments are completed, turn release switch into cross-shaft bracket until carburetor idle adjustment screw starts to break with low step of fast idle cam. Back off the anti-creep release switch three complete turns and secure with locknut. Install wire and test operation.

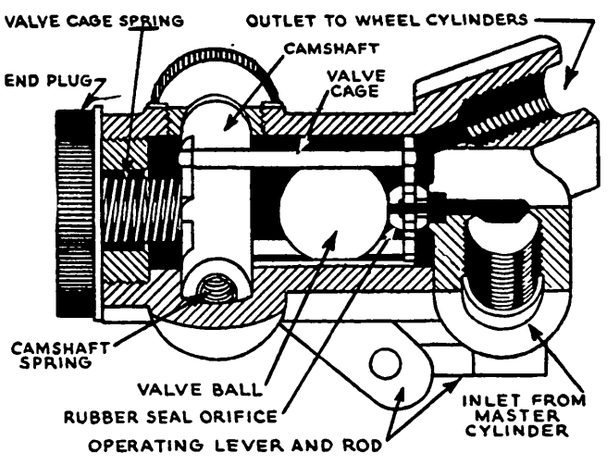
Linkage Adjustment: *See "Studebaker" Automatic Transmission in Transmission Section.*

CHECKING OPERATION: 1) While driving car at approximately 10 MPH, selector lever in "D" position, quickly apply and immediately release brakes. **Do not touch accelerator pedal.** Car should roll freely with no evidence of brake drag after brake pedal is released.

2) While driving car on level ground, release accelerator pedal and apply brakes, bringing car to complete stop. Car should not creep forward until accelerator pedal is depressed.

3) With car standing on level ground and engine idling, selector lever in one of "D" positions, and with anti-creep system preventing car from creeping, touch accelerator pedal lightly, then release it. Car should creep slowly from a standstill.

HILL-HOLDER & NOROL



Std. or Optl. Equipment On:

ALL CAR MODELS WITH HYDRAULIC BRAKES

DESCRIPTION:—These units consist of a gravity and clutch pedal controlled check valve in a housing which is ordinarily mounted directly on the end of the hydraulic brake Master Cylinder so that the check valve is in the brake line between the master cylinder and the wheel cylinders The valve ball is free to roll endwise in the valve cage (when unit tilted by car being on an incline) while the valve cage itself is moved endwise by a cam lever linked to the clutch pedal

OPERATION:—The valve cage with the rubber seal orifice is normally held away from the valve seat by the clutch pedal controlled camshaft (with the clutch engaged) so that the valve is open and brake operation is conventional When the clutch is disengaged, the rotation of the camshaft permits the spring behind the valve cage to force the cage back so that the rubber seal seats against the valve seat If the car is pointed uphill the ball within the valve cage rolls down against the rubber seal, closing the orifice within the seal so that the brake fluid in the lines is prevented from returning to the master cylinder and brakes are held 'on' even though brake pedal is released When the clutch is engaged, the valve cage is pulled away from the valve seat uncovering the return passage to the master cylinder and releasing the brakes If the car is on a level road or pointing downhill, the ball will not close the rubber seal orifice

ADJUSTMENT:—Operating lever position must be checked (to insure correct timing of brake release when clutch is engaged) whenever clutch pedal is adjusted See Clutch pedal adjustment instructions on car model page for special instructions Adjust as follows

HILL-HOLDER & NO-ROL C NTROL UNIT

Adjustment:—Check setting by applying brake on slight incline with clutch disengaged, then shift into low gear engage clutch slowly and note point at which brakes release. If brakes release too soon and car has tendency to roll backward, loosen locknut and turn adjusting nut on end of control rod away from pedal to lengthen rod If brakes release late and engine has tendency to stall, turn nut in to shorten rod. Tighten locknut and check setting.

Mounting:—The unit must be mounted in a level position on car frame. To check, place spirit level on bosses on top of hill-holder body casting with car standing on level floor. Unit must be leveled lengthwise (place spirit level on two bosses on top of unit), and crosswise (place spirit level crosswise on one boss).

SERVICING: Before disassembly, mark shaft and lever and replace in same position Remove ball chamber head plug and spring, withdraw camshaft being careful not to lose camshaft spring, withdraw ball cage assembly In reassembling unit, see that ball cage is installed with two large ball rail rods underneath camshaft, and that camshaft spring is in place at inner end of camshaft

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 PONTIAC BRAKE SILENCER SPRINGS (To Correct Brake "Squeak"):* Brake Drum Silencer Spring Pkg. No. 514278 is available to correct above complaint. To install, make up four tools (see below) and install tools on four of the five wheel studs (use wheel nuts to hold tools in place), place spring on drum over the four tools, roll spring on drum flange using large screwdriver to pry spring on drum at point between two wide spaced installing tools. Install three clips approximately 120° apart to retain spring on drum. Remove tools and re-install wheel.

INSTALLATION TOOL NOTE–Make up tool from 1" wide strap iron with 17/32" hole centered on strap ¾" from one end (to engage wheel stud). Bend opposite end over in form of "U" 3¾" from center of hole and ¾" deep (return on end should be ½" long so as to fit over rim of brake drum).

►*1954 CADILLAC BRAKE PEDAL FREE TRAVEL CAUTION:* **The upper half of brake pedal for the standard brake is not the same as the one for power brakes. Should the incorrect upper half be installed for the standard brake the free travel will not be correct, and full brake action cannot be obtained. The correct measurement (from carpet to lower edge of brake pedal plate) for standard brake is 5¾" (Power Brake 4 7/8"). NOTE– To obtain full brake pedal travel, the rubber grommet should rest against the bottom of toe-board when brake is fully released.**

►*1954 OLDSMOBILE BRAKE RETRACTING SPRING CAUTION:* **Spring load specifications are important to obtain long life from linings. Spring load should be 45-55 lbs. when spring stretched to its normal length (4 7/8"). Free length should be 4½". Measure the distance from end of long hook to inside edge of other hook at opposite end. Replace spring when free length over 4½" or load not within specifications.**

►*1955 BUICK 40 & 60 SERIES LONG BRAKE CABLE CORRECTION (Early Cars):* To correct, disconnect rear brake cable by removing nut and cable sheave. Cut a piece of ¼" steel pipe or tubing that will slip closely over front cable rear shank to length necessary to get ample adjustment. One inch length should be adequate. Install this spacer on shank between rear cable sheave and adjusting nut. Adjust cable to proper tension and lock adjusting nut by installing a plain 5/16" nut as a jam nut and tightening securely against adjusting nut. Check with parking brake in fully applied position to be sure cable sheave does not come up to rubber grommet. There should be at least ½" clearance. If cable sheave within ½" of grommet in fully applied position, remove hand brake cable support (rubber covered bracket) and weld a new one, Part No. 1311223, one or two inches farther ahead on torque tube. Steel shank of front cable must ride in the grommet.

►*BUICK UNEQUAL, ERRATIC, OR SQUEAKING BRAKE CORRECTION:* To correct, proceed as follows: **(1)** Air tires to 24 pounds. Expand brake to a two hand drag in a forward direction (**Do not** tighten excessively so as to distort drum). **Do not** attempt to expand brake by having another mechanic apply pressure to brake pedal. **(2)** Make Anchor Pin Adjustment (See Adjustments below), and repeat adjustment until amount of drag remains constant. **(3)** Make Major Brake Adjustment (See Adjustments below). **(4)** Repeat **(2)** and **(3)** above on all remaining wheels. If any brake has noticeably more drag than others after releasing adjustment 6 notches, repeat anchor pin adjustment on that brake. If still not comparable with others, remove wheel and check brake assembly and backing plate for cause of binding and correction condition. If, during adjustments, anchor pins on one or more brakes were moved, car should be road tested. Usually, during first few applications, original condition will return and then will gradually improve until, after 15 to 20 applications, brakes will begin to operate normally.

►*1954 & EARLY 1955 CADILLAC EXCESSIVE PEDAL EFFORT CORRECTION:* When checking for cause of excessive pedal effort on 1954 Series cars and 1955 Series Cars built prior to Engine No. 22750, examine brake pedal position on shaft. If pedal has moved out over lock ring to such an extent that it is binding, replace shaft and lock ring, using new shaft. Part No. 3510310, and new lock ring, Part No. 1463434. New part numbers are applicable to 1950 through 1955 Series cars equipped with Hydra-Matic transmissions.

►*1955 CADILLAC BRAKE PEDAL BINDING CORRECTION (Cars Built Prior To Engine No. 12725):* To correct bind at clevis and bell crank linkage of brake pedal assembly, install a 1/8" flat washer between frame and master cylinder attaching bosses. After installing washer, check linkage throughout its travel and shim further, if necessary.

►*1955 CADILLAC WHEEL CYLINDER PRODUCTION CHANGE:* Effective approximately Engine No. 54000 a dish type metal expander is being used with wheel cylinder cups. Expander minimizes contraction of cups due to variations in temperature and reduces possibility of air entering wheel cylinder when fluid cools and creates a slight vacuum in cylinder. Wheel cylinders with expanders installed have copper plated bleeder screw assembly. Early cars have a zinc dichromate plated bleeder screw assembly.

►*1954-55 CADILLAC MASTER CYLINDER REPLACEMENT CAUTION:* Service replacement master cylinders for use on 1952-55 Series cars have filler cap designed for use with a remote filler reservoir. Drilled and tapped hole in center of cap for reservoir tube is plugged with red plastic cap. When replacing master cylinder on a 1954-55 Series car, plastic cap must be removed for attachment of remote filler pipe. When using a new master cylinder on a 1952-53 Series car without remote filler reservoir, filler cap must be discarded and filler cap from **ld** master cylinder used.

►*1955 HUDSON HORNET BRAKE PRODUCTION CHANGE & CORRECTION (T Eliminat N is r "Clunk"):* Effective approximately October, 1955 a brake shoe return spring with greater tension (40 lbs.) will be incorporated in production to eliminate noise or "clunk" occurring during initial pedal application in **reverse** direction. New set, Part No. 3119175, including 4 springs (2 wheels), is available for installation on earlier cars.

►*1955 HUDSON & NASH MASTER CYLINDER PRODUCTION CHANGE (To Corr ct "Spongy" Brak P dal):* Master cylinder-to-pedal shaft brace, Part No. 3141435, may not fully engage groove at outer end of pedal shaft, permitting pedal shaft to flex within keyhole slot during application resulting in a "Spongy" brake pedal. Effective at following serial numbers, production enlarged two master cylinder attaching holes in brace to effect a full engagement of keyhole slot to groove in outer end of pedal shaft: Hudson Hornet V8, Y-1483; Hudson Hornet 6, X-1226; Hudson Wasp, W-1347; Nash Ambassador V8, V-1808, Nash Ambassador 6, R-743126; Nash Statesman, K-635418. At same time two original lockwashers on brace to master cylinder attaching screws were replace! with bite washers, Part No. 3138264. When condition occurs in field remove brace and elongate master cylinder attaching holes sufficiently to provide full engagement of keyhole slot to groove in outer end of pedal shaft. When reinstalling brace use two bite washers.

►*1955 HUDSON WASP & NASH STATESMAN BRAKE CHATTER ON LIGHT PEDAL APPLICATION CORRECTION:* Chatter caused by drum distortion occuring when wheels secured to drums (ten wheel-to-hub contact ledges are not uniform in height). Generally, condition will improve with time and mileage. If chattering condition is **sever** , remove wheel and tire assemblies, and clean wheels as necessary. Color a 6½" square of plate glass with a bearing blue or colored crayon. Place the plate glass on the ten wheel-to-hub contact ledges, and oscillate the glass slightly to transfer coloring material to high ledges. With grinding equipment, gradually reduce high ledges to a point where it is not possible to place a .004" feeler gauge between plate glass and any one of the ten ledges. Repeat coloring operation as often as necessary. *Do not remov mat rial in xc ss f .015" from any one of ledges.* If necessary, replace wheel. In cases where severe chattering is encountered it is possible that one or more drums have taken a permanent out-of-round set. Check drums, and in cases where out-of-round exists in excess of .005", a light cut be taken on drum lathe to bring drum within .005" out-of-round limit.

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC (Cont.)

►*1955 OLDSMOBILE BRAKE PRODUCTION CHANGE:* Beginning approximately May 15, a second type front and rear brake assembly was used in production. Primary change in new assembly is use of larger retracting spring and a new anchor pin. In rear brake assembly, new parking brake lever and pin assemblies are used to provide clearance for larger spring, and are held to the secondary shoe by a retaining clip. A new washer is also used in rear brake assemblies between parking brake lever and secondary shoe.

►*1956 BUICK BRAKE SQUEAK CORRECTION:* A new brake anti-squeak spring Part No. 1178586 replaces early spring Part No. 1345469. It is more effective in eliminating brake squeak due to increased tension. To install, remove wheel and tire assembly, hook spring ends together, place spring over upper edge of drum and hold in place while prying spring over balance of drum. Center punch drum at five equal distance points so that point of spring retainer clip will rest in depression.

►*1956 BUICK BRAKE PEDAL TWISTING CORRECTION (DYNAFLOW MODELS WITH MANUAL BRAKES):* On early 1956 Dynaflow models a bending or twisting of the brake pedal plate can be corrected by removing the brake pedal pivot locknut, bolt and pedal as well as the dash insulator retainer. Drill a 9/32" hole through the cowl using the unused hole in brake pedal bracket as a guide. Install a ¼" x 20 x ¾" bolt, washer and locknut and tighten to cowl panel.

►*1956 BUICK BRAKE DRUM REBORE CAUTION:* If brake drum does not clean up when rebored to diameter of 12.083" it must be replaced. Excess reboring will affect dissipation of heat and cause drum distortion.

►*1956 CADILLAC BRAKE (SQUEAL) PRODUCTION CHANGE:* Effective at Eng. No. 021493, paint eliminated from brake drum silence springs and from brake drum in vicinity of springs to reduce brake squeal.

►*1956 HUDSON WASP & HORNET 6 REAR WHEEL BRAKE CYLINDER PRODUCTION CHANGE:* Beginning with Serial No. W-9403 (Wasp), No. X-9204 (Hornet), the diameter of the rear wheel brake cylinder was decreased to 7/8" from 15/16"

►*1957 BUICK BRAKE DRUM PRODUCTION CHANGE:* Motor Wheel drums now used on later production cars on front wheels only. These drums are identified by weld spots around circumference between rim and disk. *CAUTION:* If one drum requires replacement, another drum of the same make must be used. Under no circumstances should two different makes of drums be used on the same end of the car.

►*1957 BUICK ALUMINUM DRUMS:* New aluminum finned drums are used on front wheels of Models 75 & 75R. Special wheel attaching bolts are used with these drums and should not be used with other drums, nor should ordinary bolts be used with aluminum drums.

►*1957 BUICK PEDAL LINKAGE CHANGE:* A change in linkage has been made to increase the clearance between brake pedal arm and idler lever arm. This consists of rotating arm on brake pedal slightly and lengthening brake linkage link which in turn increases clearance between arm of brake pedal and arm of idler lever. New brake pedals and old shorter links are not interchangeable. However, only new pedals are available for replacement which requires a new ty, link also.

►*1958 BUICK DRUM NON-INTERCHANGEABILITY CAUTION:* Cast iron drums (Series 40 front, All Series rear) and aluminum drums (Series 50, 60, 70, 700 front only) are used. Two types of each used (see below) and drums on right and left sides of car must be alike. DO NOT intermix drums.

Cast Iron Drums - Buick and Motor Wheel types used. Motor Wheel drums identified by weld spots around circumference between rim and disk.

Aluminum Drums - Early type have aluminum pegs in iron liner, later type do not.

►*BUICK CAST IRON DRUM FLAKING CAUTION:* When scale is present on edges and in corners of drums, remove with a chisel and hammer, by tapping lightly. This will prevent scale becoming embedded in lining.

►*1957-EARLY 1958 CADILLAC ANCHOR PIN PRODUCTION & TORQUE SPECIFICATION CHANGE:* Heat treated anchor pin nut No. 225857 (identified by three grooves on face of nut) replaced Nut No. 120371 beginning with 1958 Engine No. 038946. This nut should also be used on all 1957 cars. All three backing plate nuts and new anchor pin nut should be tightened to 80-100 ft. lbs.

►*1957 CADILLAC SILENCER SPRING ELIMINATION:* Effective Engine No. 012025 the brake drum silencer spring has been eliminated.

►*1957 CADILLAC "BUZZING" NOISE CORRECTION:* To eliminate "buzzing" or gurgling noise in power brakes caused by air trapped at control valve assembly, thoroughly bleed hydraulic system - twice if necessary. If condition is not corrected, check for leaks.

►*1957 HUDSON & NASH PARKING BRAKE PRODUCTION CHANGE:* A new parking brake cable bellcrank return spring is attached to bellcrank and torque tube. An anchor is welded to torque tube to hold it. Return spring hooks into eye of cotter key at bellcrank.

►*1958 CADILLAC BRAKE SHOE RETRACTING SPRING PRODUCTION CHANGE & CAUTION:* Larger diameter (7/8") brake shoe retracting spring No. 5456495, replaced spring No. 497834 (1/2") on all series FRONT wheel brakes starting with Engine No. 017126. All four front wheel retracting springs must be of same type. All four rear wheel retracting springs (1/2") must be same type (two types - Tile Red and Dark Maroon).

►*1958 CADILLAC PARKING BRAKE PEDAL NO RETURN CORRECTION & PRODUCTION CHANGE:* Make parking brake adjustment as detailed under "Hand (Parking) Brake Adjustment" below. Make sure there is not even a slight bind in brake cable in area of No. 2 body hanger. Entire parking brake pedal assembly must be lubricated and excess friction at pivot points eliminated. Beginning Engine No. 042388, a new pedal assembly with improved locking quadrant entered production on some cars. This pedal uses the 35 lb. retracting spring. At the same engine number, a new 55 lb. retracting spring, Part No. 1472158, was used on cars still having early type pedal assembly. Use 55 lb. spring on early cars if above adjustments and checks do not make brake pedal release.

►*1958 CADILLAC SERIES 75 PARKING BRAKE CABLE PRODUCTION CHANGE:* Beginning Engine No. 058306, parking brake cables were lengthened ¾" to aid in more accurate brake adjustment.

►*1958 OLDSMOBILE PARKING BRAKE HARD APPLICATION AND POOR RETURN CORRECTION:* Caused by binding of front cable at frame bracket which may be bent out of position. To correct, bend bracket so it is at 90° angle to centerline of car.

►*1960 PONTIAC REAR BRAKE ANCHOR PIN NOTE:* Anchor pins on rear brakes are not adjustable (riveted to backing plate). In conjunction with "riveted" anchor pin, production brake drums will not have a feeler slot.

DESCRIPTION: Single anchor, hydraulic type. Fixed anchor pins are used on 1959-60 Oldsmobile and Rambler, 1960 Valiant (front and rear wheels) and on 1960 Pontiac (rear wheels only). Fixed anchor pins are not adjustable and have no major adjustment.

ADJUSTMENTS: Before attempting any adjustments, car should be placed on stands with wheels free. Brake pedal should operate freely and there should be no bind in hand brake lever or cables.

Brake Pedal Adjustment: This adjustment should conform with recommendations before any other adjustment is made. See Car Model below.

Buick - Clearance between pedal and under side of toe board should be 1" (1954), 15/16" (1955). (1956) - No pedal adjustment necessary. Pedal must return to fully released position (piston guide contacting bumper washer). (1957-58) - Make sure large nut holding master cylinder to cowl is tight; tighten brake pedal mounting bracket attaching bolts. Measure from left top side of pedal pad perpendicular to toe pan. With ruler pressed firmly against floor mat, pedal height should be 7½-8" (Std. Brakes through 1959), 5½" (Pwr. Brakes 1957-58). 1959 Pwr. Brakes and 1960 Std. & Pwr. Brakes do not have pedal height adjustment. Adjust by turning pushrod to obtain desired height. *NOTE* - On synchromesh cars, pedal height is same as clutch pedal height.

Cadillac - Rubber grommet on pedal under toe board should just touch underside of toe board (1954-55), (1956) - With power brake pushrod in fully released position, distance between front edge of groove in pedal-to-relay rod and toe board should be 7/8"±1/16". Screw relay rod into or out of trunnion relay to obtain this distance.

(1957-58) - With power brake pushrod in fully released position, pull carpet away from pedal-to-relay rod seal and check distance between pedal reinforcement and seal retainer. Distance should be 4 7/8"±1/8". Screw relay rod into or out of trunnion relay to obtain this distance.

(1959-60) - *See "Pushrod" adjustment in "Bendix Hydraulic (Disc) Reaction" Type, reassembly of Power Brake Unit.*

Hudson & Nash—Pedal free travel should be ¼-½" with master cylinder piston against stop. Adjust at master cylinder pushrod.

Oldsmobil - Two adjustments required.

P dal H ight - 8¼" minus 1/16" from top of brake pedal to top of floor pan. Adjust by loosening locknut and turning stopscrew on underside of brake pedal bracket.

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC (Cont.)

Pedal Free play - 3/16" pedal free travel before pushrod contacts master cylinder piston. To adjust, loosen locknut on the pushrod and adjust pushrod length.

Packard—Brake pedal should have ¼" free play with master cylinder piston against stop. Adjust at master cylinder pushrod.

Pontiac - (1954-57) - Clearance from power side of pedal pad to floor mat with master cylinder piston against stop should be 4 3/8-4 5/8"

(1958) - Adjust pedal stop bracket to give 5½-5¾" pedal height from bottom of pedal to floor mat. Stop lights must operate after ½" pedal travel. Reset pedal stop and bracket separately to correct. Then adjust length of master cylinder pushrod to give 1/64-1/32" clearance between forward end of pushrod and socket seat in master cylinder piston. Tighten locknut.

(1959-60) - Adjust pedal stop bracket to give pedal height from bottom of pedal pad to floor mat as follows: 6¼-7" for 1959 (Std. Brakes), formerly 6¾-7", 3¾" (Pwr. Brakes), formerly 3¼". When pedal height changed, adjust stop light switch so 1/8" of plunger shows when pedal fully released. *CAUTION* - DO NOT lengthen pushrod beyond clearance specification. Primary cup of master cylinder must be completely clear of compensating port.

CAUTION - Do not lengthen pushrod beyond clearance specifications. Primary cup of master cylinder must be completely clear of compensating port.

Rambler - Pedal freeplay should be ¼-½". Adjust by rotating pushrod eccentric bolt. *NOTE* - Compensating port in master cylinder must be wide open when brake pedal is in fully released position. *CAUTION* - Minor adjustment only is made on 1955-57 Nash & Hudson models (anchor pin is fixed)

► *CAUTION:* Minor adjustment only is made on 1955-57 Nash & Hudson models (anchor pin is fixed).

Valiant - No adjustment provided

Minor Wear Adjustment: Check and adjust the brake pedal clearance, then release the hand brake lever, and check to see that the cables are free and are not holding brake shoes against the drum. At each wheel, expand brake shoes by turning adjusting screw up until wheel can just be turned by hand, adjust hand brake (cars where hand brake adjusted with shoes "expanded"-see Hand Brake Adjustment), then back off adjusting screw the number of notches or "clicks" as shown in table below. Check wheel for freedom of drag. If drag noted, tap backing plate to assist centralization of shoes, then recheck. If drag still exists, anchor pin adjustment may be in order. See Major adjustment.

Adjusting Screw Setting

Buick	① 15 notches
Cadillac	14 notches
Hudson & Nash	14 notches
Oldsmobile	16 notches
Packard (1954-56)	②
Pontiac (1954-57)	14 notches
Pontiac (1958-60)	12 notches
Rambler	③ 8 notches
Valiant	10-12 notches

① - Additional 1-2 notches if brakes still drag

② - Turn brake adjusting screw up until wheel can just be turned by hand, then back off screw until wheel turns free. ③ - 10 notches with new lining

Major Adjustment (For New Shoes, Relined Brakes or when Minor adjustment not satisfactory). Jack up all four wheels, loosen or disconnect parking brake cables at equalizer or intermediate lever, remove adjusting hole covers on backing plate and inspection hole cover on drums (remove wheels for access). Check Pedal Clearance (see Brake Pedal Adjustment). Adjust each wheel brake as specified by car manufacturer, given below. *CAUTION*—If hand brake cables not disconnected or loosened, shoes may be held "ON" by cables.

Buick—Turn adjusting screw up to expand shoes until wheel can just be turned with both hands (if wheel off, drum should just turn with long bar). Back off 15 notches. (Max. 17 notches). Wheels should be free at approximately 6 notches. If not it indicates need for anchor pin adjustment or tight parking brake cables.

Anchor Pin Adjustment—Loosen anchor pin nut ½ turn just enough to permit anchor pin to slide in the slotted hole. *(CAUTION*—Loosening anchor pin nut too much will allow brake shoe spring to tilt pin), rap backing plate with hammer adjacent to anchor pin to insure anchor pin assuming central position between shoes, tighten anchor pin nut securely, then recheck drag. (If this has changed recheck anchor pin adjustment). Check and adjust hand brake (see Hand Brake Adjustment). Wheels should be free of any drag.

1952-58 Cadillac - Loosen anchor pin locknut ½ turn, tap anchor pin up with a hammer, then all the way down to bottom of its slot. On front wheels it will be necessary to loosen backing plate upper mounting studs slightly and tap anchor pin up, then all the way down to bottom of its slot. Turn adjusting star wheel to expand brakes until wheel can just be turned with two hands. Tap backing plate near anchor pin to raise it to a central position between shoes. Check brake drag. If centering of anchor pin has released brakes, increase expansion of shoes and reset anchor pin again. Repeat until there is no change in drag with change in anchor pin setting, then tighten anchor pin to 80-120 ft. lbs. torque. Loosen star wheel 14 notches, place .015" feeler through drum slot at bottom and rotate wheel until feeler is wedged between secondary shoe and drum. Primary shoe will be tight against drum for measuring secondary clearance. Reverse wheel rotation until .015" feeler is again at bottom and adjust star wheel to obtain .015" clearance. The clearance at top of shoe should now be .010". If upper clearance is greater or less than .010", loosen anchor pin locknut and reset anchor pin, tapping it up to increase clearance and down to decrease clearance. Reset clearance at lower end with star wheel and recheck upper clearance.

Hudson & Nash (1954); Oldsmobile (1955), Pontiac (1954-59, All Wheels), 1960 Front Wheels. Insert a 015" feeler in slot 1½" from adjusting screw end of secondary shoe, turn screw up to expand shoes so feeler tightly gripped (to move primary shoe out against drum), then back off screw until only a slight drag is felt on the feeler gauge (will insure .015" clearance at this point). Check clearance at point 1½" from anchor pin end of this same secondary shoe. If .015" feeler does not have equal or slightly heavier drag at this point, adjust anchor pin (see notes below on slotted and eccentric type anchors) for correct .015" clearance at this point, tighten anchor pin nut to 75 ft. lbs. torque. Adjust hand brake, check and adjust brake pedal clearance (below).

Eccentric Anchor Pin— Pin has squared end. Can be turned with a wrench after nut has been loosened. Turn pin in direction of forward wheel rotation to decrease clearance. End of anchor pin is beveled and high point indicates high side of eccentric cam. Hold pin with wrench while tightening nut.

Slotted Anchor Pin Hole—Pin hole in the backing plate is slotted. To adjust, loosen anchor pin nut and tap pin out toward drum to decrease clearance.

1955-57 Hudson & Nash - No major adjustment. Anchor pin is fixed.

1956-58 Oldsmobile. Expand shoes until heavy drag felt on brake. Release adjusting screws approximately 16 notches (until brake drums are free of drag) and replace adjusting screw hole covers. Move adjusting screw end at primary shoe against drum by inserting screw driver into slot provided in drum, then turn drum backward to force end of primary shoe against drum. Check clearance at anchor and adjusting ends of secondary shoes with .015" feeler inserted in brake drum slot. Clearance should be equal to within .002". If not adjust anchor and adjusting screw as required. *NOTE* - Clearance at anchor end should not be more than at adjusting screw end.

Packard—Insert a .015" feeler gauge through inspection hole in drum at point 1½" above lower end of secondary shoe. Expand the adjusting screw (star wheel) until a slight drag is felt on the feeler. Remove feeler and insert a .010" feeler through inspection hole in drum at a point 1½" from upper end of secondary shoe. If clearance not within limits, loosen anchor pin locknut and adjust anchor pin. Turn anchor in direction of forward wheel rotation to decrease clearance. At the same time readjust the adjusting screw to maintain .015" clearance at lower end of shoe. Hold anchor in set position and tighten locknut. Turn clearance adjusting screw (star wheel) until drum can just be turned with both hands, then back off screw until drum turns freely (1954-56)

Hand (Parking) Brake Adjustment: *CAUTION—Brake shoes must be expanded on some cars when adjusting hand brake cables.* Adjust each car as follows

Buick (1954-58) - *CAUTION* - DO NOT adjust parking brakes by simply tightening adjusting nut at brake cable sheave. Pull on both ends of rear brake cable to make sure cables operate rear brake shoes freely and do not bind in conduits. Cable must be free in sheave and spring must return lever to fully released position. Adjust brakes at anchor and adjustment screw as described in minor or major brake adjustment. *NOTE* - When brake lever is in fully released position signal switch plunger must be depressed 3/16". Adjust by loosening mounting screws and relocating switch.

Buick (1959-60) - *Make Parking Brake Adjustment when never service brake pedal has good reserve but Parking brake pedal depresses to within 3" of toeboard.* Make Minor Adjustment (see above). Release brake. Cable should have approximately 2" slack when pulled down midway between conduit clip and cable sheave. Adjust cable length at equalizer by holding cable end (to pre

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC (C nt.)

vent twisting) and turning adjusting nut. Make sure rear wheels are free when brake lever fully released.

Cadillac - Make Minor Service Brake Adjustment (see above). Replace relay lever spring if weak or broken. Release pedal. Intermediate cable tension is correct when the ¼" diameter of Gauge Tool J-7503 is a slip fit between relay lever and end of slot in frame. Adjust intermediate cable at front clevis as necessary. Back off equalizer nut so the 1 3/16" portion of gauge will slip between relay lever and end of slot in frame. *NOTE - Cable should have slack when 1 3/16" portion of gauge is in place.* Tighten equalizer nut until rear wheels drag when turned in forward direction. Remove gauge. Parking brake lever should travel 2 1/8 to 2 3/8" with approximately 50 lbs. pressure at pedal.

1954 Hudson - With brake shoes expanded so wheels can just be turned by hand, pull hand brake lever "ON" two notches and check clearance between hand brake cable lever and end of slot in lever guide plate on frame cross-member. If this clearance is not 1/8", loosen locknut and adjust hand brake cable clevis. Pull each rear brake cable taut and adjust clevis on forward end of cable so that clevis pin can just be inserted with all slack removed from cable. Connect cables, release hand brake lever, back off adjusting screw 14 notches for correct shoe clearance, check brake equalization.

1954 Nash - **Do not expand shoes.** Pull hand lever "ON" exactly 3½" (measure from face of bracket to handle). At rear cable equalizer, loosen forward nut and tighten rear nut on hand brake lever cable fitting until rear brakes are fully applied, then tighten forward nut. Release hand brake lever and check brakes for freedom from drag.

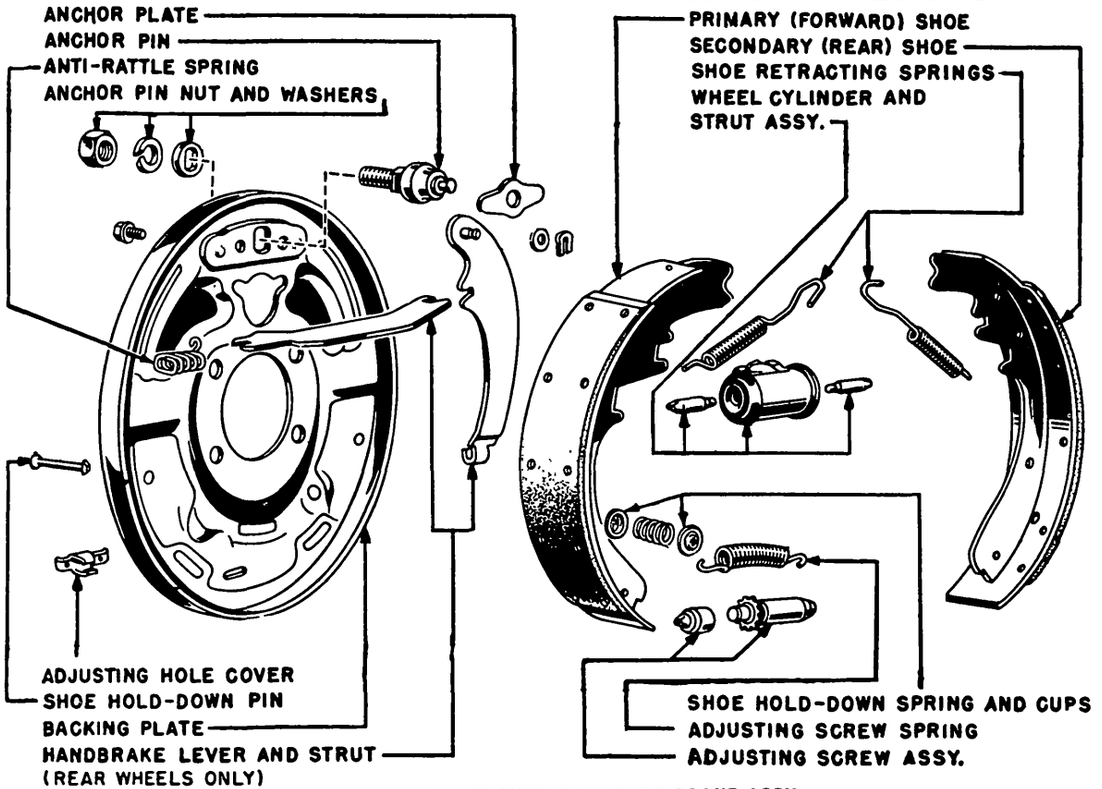
1955-57 Hudson & Nash - Pull hand brake lever to rear to provide a 3½" clearance between hand brake lever handle and bracket face. With lever in this position, tighten hand brake cable at equalizer to a point where rear brakes are fully applied. This will prevent possible brake drag. To release parking brake, apply brake pedal pressure, turn parking brake handle counter-clockwise 70° and push it into released position.

1954-55 Oldsmobile - With hand lever **released** and service brakes properly adjusted, adjust hand brake front cable so that hand brake intermediate lever is held from seating itself on the end of the seat in the left "X" member by 1/32-3/32". Adjust rear cables to remove all possible slack without moving brake shoes from released position. Rear cables must not protrude into clevis more than ¾". The threaded part of front cable must extend entirely through front clevis. Distribute the adjustment between rear cables so that equalizer link is parallel to propeller shaft when clevis pin can just be dropped into place. Lock clevis jam nuts and insert clevis pins. Always install clevis pins with head on top.

1956-58 Oldsmobile - Release brake, and make minor brake adjustment if there is excessive brake pedal travel. Adjust front cable so that the intermediate lever is held from seating itself on end of the seat in left hand "X" member by ½". Adjust rear brake cables to remove all possible slack without moving brake shoes from released position. Distribute the adjustment between cables so that equalizer link is 90° to the propellor shaft when clevis pin installed. Lock clevis jam nuts and install cotter pins. Install clevis pins with head at top.

1959-60 Oldsmobile - Release parking brake, and make minor brake adjustment if brake pedal-to-floor board clearance is less than 2" (1959), 4" (1960) standard brakes, or 1" (1959), 1¾" (1960) power brakes. Adjust the front cable so that the intermediate lever is held from seating on end of seat in left "X" member by ½". Adjust rear cables by tightening equalizer nut until heavy drag is felt at rear wheels, then loosen equalizer nut 6 full turns (1959) 10 full turns (1960) and tighten jam nut.

Packard—Tighten adjusting screws until wheel can just be turned by hand. Pull hand lever to first notch on ratchet. Adjust clevis on hand brake cable so that the clevis pin can be easily installed without any slack in the cable. Release hand brake lever. Back off adjusting screw at each wheel until wheel turns freely. Apply hand brake and check equalization by turning each wheel by hand. If not equal, loosen adjusting screw on tighter brake. Replace hole covers and road test.



1954-60 Pontiac - Apply hand brake to first notch and then check equalization. Loosen adjusting screw of tightest brake if not equal. If more than a few notches are required, loosen clamp screws on spreader and pull downward on the tight side of cable. This should equalize cable. Tighten spreader clamp screws while hand brake lever is still in the applied position. Brake cables are sufficiently tight if rear wheels can barely be turned by hand with lever in first notch. When lever is fully released, wheels should turn freely with cable pulled down approximately 1½" by gripping cable midway between conduit and clearance hole through frame X-member. When adjusting rear end of front cable for close adjustment for tension, be sure to turn clevis on or off cable end but do not twist cable. Coarse adjustment is secured by selecting the correct hole in the spreader.

Rambler (Hand Operated Type) - Pull handle back to give 3½" clearance between handle and mounting bracket. Tighten cable at equalizer until brakes are fully applied.

Rambler (Foot Operated Type) - With lever in fully released position adjust rear cable at equalizer so wheels will turn without drag.

1960 Valiant - With rear brakes properly adjusted (minor adjustment), release parking brake foot lever completely, then slacken front cable until intermediate arm (ratio bar) seats on cross-over stop. Tighten rear cable adjusting nut until rear wheels drag and are dif-

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC SINGLE ANCHOR BRAKE ASSY.

BENDIX HYDRAULIC (C nt.)

ficult to turn, then slacken rear cable adjusting nut until rear wheels rotate freely. Continue to loosen rear cable adjusting nut **three additional turns.** Secure rear cable equalizer in this position with locknut (forward side of equalizer). Tighten anchor nut on front cable until intermediate arm pulled off cross-over stop. *NOTE - Leave 1/16-1/8" gap between arm and stop with nut s ated in intermediate arm.* Apply foot lever several times and check to make sure rear wheels rotate freely without dragging when foot lever released.

RELINING BRAKES: Manufacturer recommends use of replacement shoes furnished with new linings. If shoes relined, use the same type lining as fitted originally (see Car Model page). Lining on primary and secondary shoes may be of different types (woven on primary, moulded on secondary, etc.) or of different lengths.

BRAKE DRUM GRINDING: If new .030" oversize shoe assemblies are to be installed, machining must not remove more than .030" on drum radius or .060" on diameter.

BLEEDING BRAKE SYSTEM OR OVERHAULING BRAKE UNITS: *See "Hydraulic Brake Servicing".*

► *BLEEDING POWER BRAKE NOTE:* Bleed power brake master cylinder first by attaching bleeder drain hose to fitting on end of master cylinder, backing off fitting ¾ of a turn and bleed fluid into a partially full bottle of clean brake fluid until bubbles cease. Then proceed as for standard master cylinder.

► *1957-58 BUICK FILLING & BLEEDING CAUTION:* Avoid spilling fluid on backing plates of finned aluminum drums as the perforated construction of these drums may cause fluid to come into contact with linings and cause damage.

TROUBLE SHOOTING: *See "Hydraulic Brak Trouble Shooting".*

Ⓒ - Bendix Single Anchor also used.

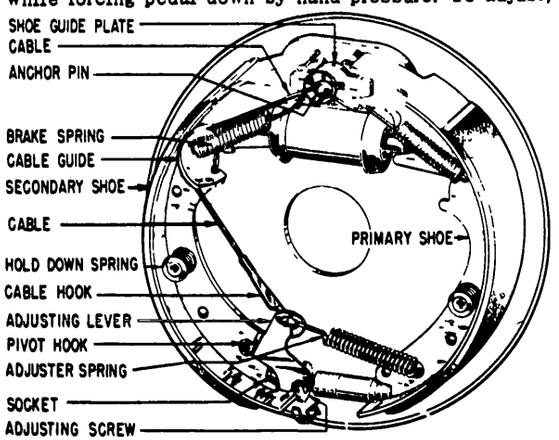
►CHANGES, CAUTIONS, CORRECTIONS

► *1960 LINCOLN REPEATED LOSS OF PARKING BRAKE ADJUSTMENT CORRECTION (EARLY CARS):* Check parking brake equalizer lever for buckling or bending and replace with Part No. COLL-2A606-C if necessary. The later type lever entered production approximately 10-28-59.

► *1960 LINCOLN BRAKE DRUM PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* A new "flared-type" brake drum is used in production starting approximately Nov. 23, 1959. Do not interchange with previous type non-flared drum as intermixing of the two parts will cause an erratic, uneven brake action.

► *1960 LINCOLN INSUFFICIENT BRAKE PEDAL RESERVE CORRECTION:* A low brake pedal or insufficient pedal reserve can be correcgtd by installing a revised brake pedal-to-brake booster operating lever link, Part No. COLL-2466-A. Make sure the brake system is in good operating condition and the low pedal or insufficient pedal reserve is not caused by leakage, adjustment, air in system, or by low hydraulic fluid. *CAUTION - Because of the slight dimensional differences between early and later type links, make sure the proper link is installed. The dimension between holes is 2.700" (early type), 2.600" (later type).*

► *1960 MERCURY "THUMPING" NOISE (WITH LIGHT BRAKE APPLICATION UNDER 30 MPH) CORRECTION:* Remove drum (or drums) and carefully cut drum .003-.005" (make two cuts to assure a smooth surface), then sand with fine sand paper. Use a fine sand paper and sand brake linings lightly. On cars with one brake shoe hold-down spring, remove and discard each spring and replace with springs, Part No. TDAA-2068-A (color black). If car is equipped with two brake shoe hold-down springs on each shoe, DO NOT replace springs.



DESCRIPTION: Similar in design to previous Bendix Single Anchor (Without Eccentric) brakes and incorporating an automatic adjuster to maintain proper lining to drum clearance. The automatic adjuster uses movement of rear (secondary) shoe during a reverse brake application to turn brake adjusting screw a small amount after a predetermined amount of wear on front and rear linings. The adjuster consists of a steel cable with a hook and anchor fitting permanently attached, a cable guide, adjusting lever, adjusting screw, pivot nut, socket and spring.

OPERATION: When lining has worn enough to require adjustment (approximately .0005" on each shoe), secondary shoe on which adjusted is mounted moves far enough from shoe anchor during a **reverse** application to cause cable to lift adjuster lever into engagement with the next tooth in the adjusting screw. When brake is released, secondary shoe returns to the anchor. Movement of the adjusting screw is 1/24th of a revolution each time it is moved by the adjuster. In forward braking, adjusting parts move with secondary shoe as a unit, and there is no lifting of the lever to engage a new tooth in adjusting screw.

INSPECTION: Inspect adjuster and brake assemblies every 10,000 miles (Edsel, Lincoln, Mercury), 16,000 miles (Rambler). Check master cylinder fluid and parking brake at normal service intervals.

ADJUSTMENTS: Make adjustments with drums cool and contracted. If car raised on frame hoist, disconnect parking brake cables.

Pedal Freeplay: (Edsel & Mercury) - 1/4-7/16". Measured while forcing pedal down by hand pressure. To adjust, loosen nut on eccentric bolt and rotate bolt.. When adjusted, tighten nut to 22-28 ft. lbs.

BENDIX AUTOMATIC ADJUSTER ASSEMBLY

(Lincoln) - Freeplay 1/4-3/8".

(Rambler) - Std. Brake Freeplay 1/4-1/2".

Brake Shoe Adjustment: *NOTE - Anchor pins ar fix d in backing plate and no major adjustm nt is r quired.*

On Car (Edsel & Mercury) - When the amount of reverse braking is not sufficient to maintain proper brake shoe to drum clearance the following procedure should be used: Raise car, remove adjusting hole cover, turn adjusting screw upward from backing plate side to expand shoes (use Tool 2018 or screwdriver), until wheel is locked. **Hold adjusting scr w lev r away fr m scr w,** back off screw until wheel turns freely, then back off screw one more notch (approximately 12 strokes – there will be no "clicking" during this operation). Make sure there is no brake drag, replace adjusting hole cover, and then make several reverse stops to complete final adjustment.

On Car (Lincoln & Continental) - Raise car, disconnect parking brake cables. Remove adjusting access hole covers. Rotate wheel. If drum drags on lining at any point in wheel rotation, hold adjusting lever (use small pointed tool through hole in backing plate) away from star wheel and turn star wheel downward (upward motion using pry lever through hole) to bring shoes away from drum. Expand shoes by turning star wheel in opposite direction until a slight drag is felt at some point in wheel rotation, then replace hole cover. Repeat operation on other wheels, and connect parking brake cables. Drive car in reverse, apply brakes 5-6 times to allow adjuster to complete adjustment as necessary.

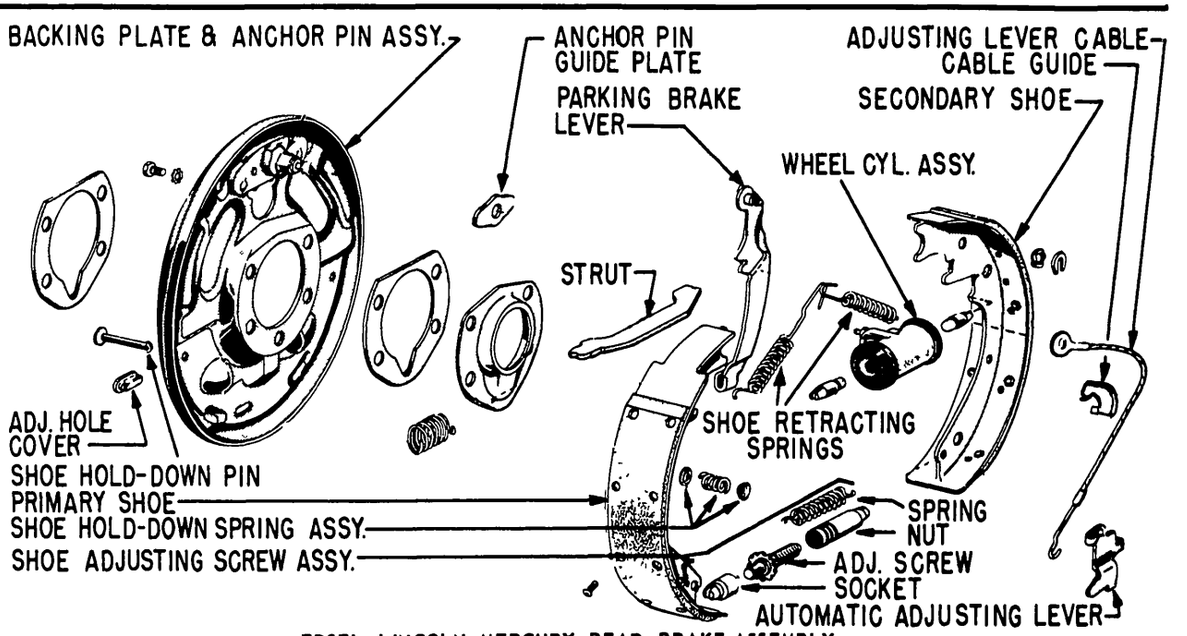
Initial Adjustment After Disass mbly: Eds l, Linc ln & Mercury - For initial adjustment after overhaul, measure inside diameter of brake drum. Raise adjusting lever, turn adjusting screw to expand shoes so the diameter (use calipers) is .030" (1/32" approximately) less (measured across shoes and lining 90° from anchor) than diameter of drum. When calipers are not available, wheels and drums should be installed and initial adjustment made as outlined under **Adjustm nt** above. Drive car cautiously in reverse, while making 7 or 8 brake applications.

Rambler - Lengthen adjusting screw to expose 3/8" of adjusting screw threads, then install drum. Drive car

CONTINUED ON NEXT PAGE

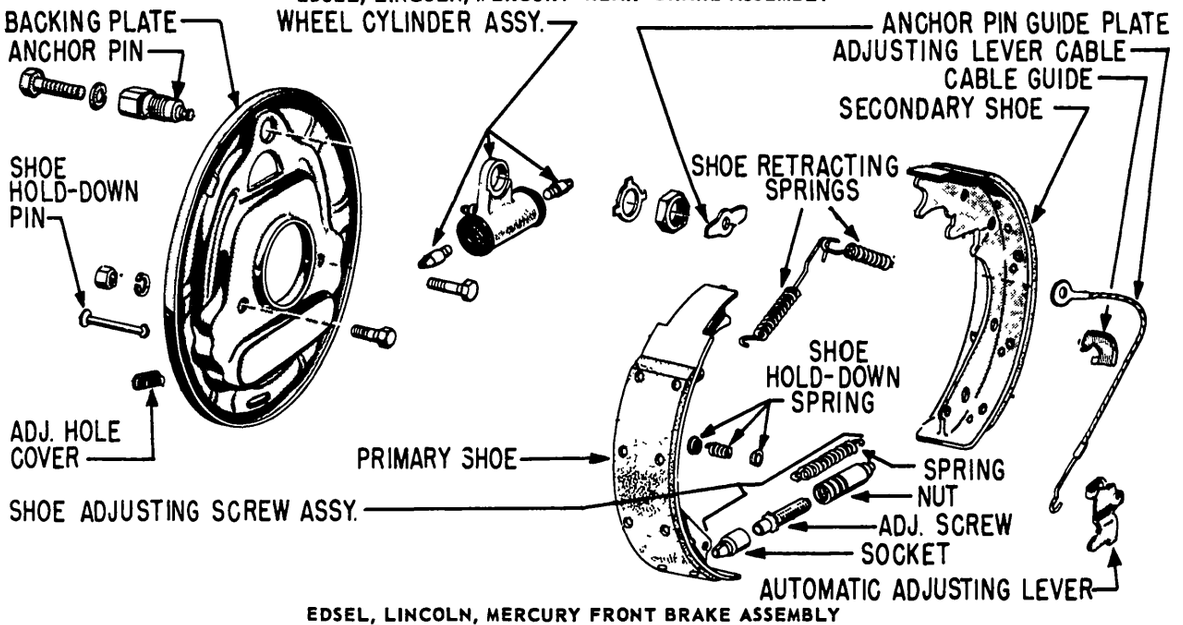
BENDIX AUTOMATIC ADJUSTER HYDRAULIC (C nt.)

cautiously in reverse, making 7 or 8 brake applications before road testing.



Parking Brak Adjustm nt: Edsel, Lincoln, Mercury - Release parking brake pedal, raise car, then loosen parking brake cable at equalizer lever. Depress parking brake pedal 1" (Edsel & Mercury), 1¾" (Lincoln) from its normal released position. Adjust front and rear cables until a slight drag is felt when turning rear wheels. *NOTE - Th adjustment should be evenly divid d b tw en the two cables to maintain proper qualizer l v r acti n.* On Mercury, the equalizer lever will be properly positioned when the distance from rear cable clevis pin on equalizer bar to rear face of cross-member (to which parking brake bracket is attached) is 5½", with parking brake pedal fully released. Tighten locknut on equalizer rod, then release parking brake and check to make sure that shoes return to fully released position. Depress parking brake pedal 2". Under normal conditions, this will hold car satisfactorily.

Rambler (Hand Op rat d Type) - Pull handle back to give 3½" clearance between handle and mounting bracket. Tighten cable at equalizer until brakes are fully applied.



Rambl r (F t Operat d Type) - With lever in fully released position adjust rear cable at equalizer so wheels will turn without drag.

Automatic Adjuster: Rem val - Disengage adjusting lever from adjusting screw by pulling backward on lever. Move outboard side of adjusting screw upward and back up pivot nut as far as possible. Pull adjusting lever, cable and adjusting spring down toward rear to unhook pivot hook from large hole in secondary shoe. *CAUTION - DO NOT pry pivot hook out of hole.* Remove anchor springs and unhook cable anchor. Remove shoe guide plate. Remove cable guide from secondary shoe and remove shoe hold-down springs, shoes, adjusting screws, pivot nut and socket.

Installati n - Install brake shoes on backing plate with hold-down spring pin, springs and cups. Install parking brake link and spring. Connect parking brake cable. Install shoe guide plate on anchor pin. Place cable anchor over anchor pin with crimped side toward backing plate. Install primary and secondary shoe to anchor springs. *CAUTION - Be sure that cable end is not cocked or binding on anchor pin.* Install cable guide on secondary shoe web with flanged hole fitted in hole in web. Thread cable through guide groove, not between guide and shoe web. Turn adjusting screw in to limit of threads then back off ½ turn. *CAUTION - Place left hand screw on right sid of car, right hand screw on left sid of car.* Install adjusting socket on screw, place assembly between shoe ends with adjusting screw nearest secondary shoe. Hook cable hook into hole in adjusting lever from backing plate side. Place pivot hook into large hole in secondary shoe web. Place hooked end of adjuster spring into large hole in primary shoe web and loop end of spring to adjuster lever. Check action of adjuster by pulling cable toward secondary shoe to lift lever past tooth. Spring will pull lever to original position (when cable released) advancing screw one tooth (1/24 revolution). Lever should contact adjusting wheel 3/16±1/32" above centerline of screw. Cable length should be 11 1/8±1/64". Cable guide groove should be parallel with shoe web and body of guide should be flat against web. Pivot hook surfaces should be square with body of lever. Adjusting screw must be seated properly in shoe web. Replace damaged or incorrect parts. Follow adjustment procedures given above.

EDSEL, LINCOLN, MERCURY REAR BRAKE ASSEMBLY

TROUBLE SHOOTING: *See "Hydraulic Brak Tr ubl Shooting" in Brak S cti n of Manual.*

BENDIX (LOCKHEED) SELF-CENTERING

Nash Statesman (1954)
Rambler (1954-56)
Rambler 5710 Series before Serial No. D-360492 (1957)①
Rambler 5901, 10 Series (1959)③
Rambler 6001 (1960)②
Willys, All Models (1954-60)

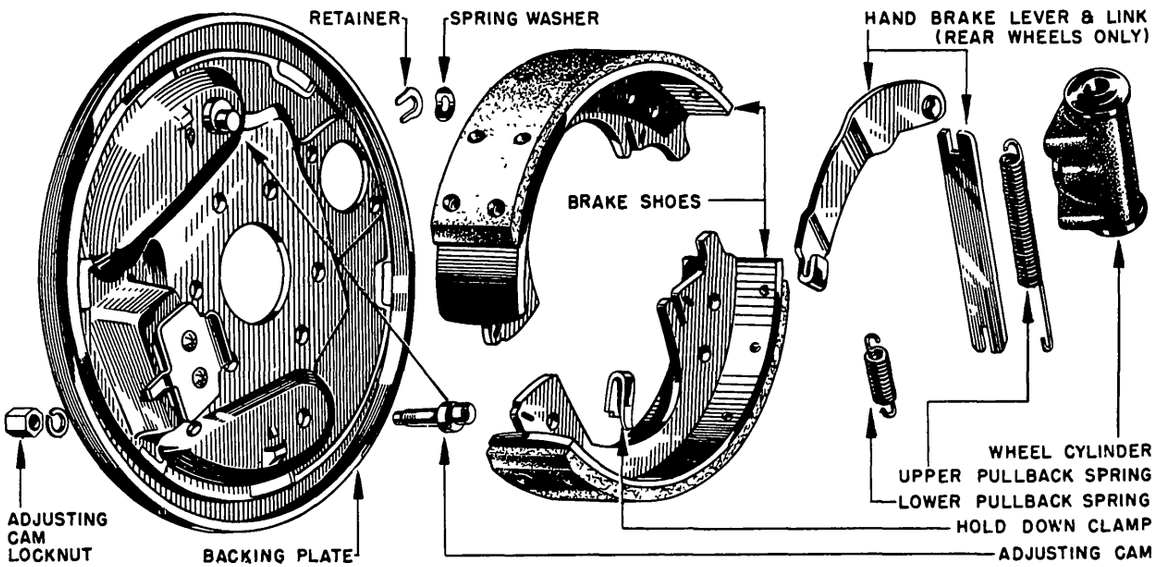
① - Later Rambler 6 Cyl. Cars have Wagner-Lockheed Self-Centering brakes.

② - For cars with automatic adjuster brakes, see "Bendix Automatic Adjuster Hydraulic Brakes".

③ - Used in limited production. See *"Wagner-Lockheed Self-Centering" for Std. production.*

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 RAMBLER BRAKE SQUEAK CORRECTION (Due t Improper Lining-to-drum Contact):* If minor, sanding of lining surface to eliminate visible high spots, may eliminate condition. If severe, shoe support plate contact area may be causing a rocking action on the three embossed ledges of support plate. To correct, remove shoes from support plate and without use of return springs or hold down clips, place each shoe individually in its proper operating location on the three embossed ledges of support plate. Check for any rocking action of shoe on support plate. If found, grind off sufficient material from center of shoe contact edge to eliminate rocking action. Grinding action should cover an area approximately 2" long on shoe edge where it contacts center embossed ledge of support plate. It may also be necessary to lightly dress up the end shoe contact edges to provide proper shoe-to-support plate contact. Lubriplate support plate embossed ledges and shoe pivot points. Reinstall shoes. Make anchor lip adjustment by bending anchor lip slightly toward brake support plate so that 15 lbs. pressure is exerted by spring to retain shoes on support plate (this can be measured with spring scale hooked to end of shoe).



►*1960 RAMBLER AMERICAN REAR WHEEL BRAKE SUPPORT PLATE PRODUCTION CHANGE:* Beginning with Car Code 20215, a new support plate (backing plate) is being used on rear wheels which utilizes a brake shoe anchor pin guide plate, Part No. 3202470, installed between brake shoes and retracting springs.

►*1960 RAMBLER "POPPING" & "SNAPPING" AT FRONT BRAKES (DURING BRAKE APPLICATION) CORRECTION:* This condition may be due to tool marks remaining in brake shoe contact area of drum. To correct, remove tool marks with abrasive cloth or buffing stone.

►*1960 WILLYS (EXC. JEEP & JEEP DISPATCHER) BRAKE SHOE RETURN SPRING PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A new spring, Part No. 924057, identified by an extended portion ½" longer than previous spring and with hooked end of spring (not extended portion) bent away from center of spring, is being used in production and should be used for service replacement.

►*WILLYS FORWARD CONTROL MASTER CYLINDER NOTE:* Master cylinder mounted on inside front panel of cab, just underneath instrument panel. Access to filler plug is through hole cover on panel to right of speedometer.

DESCRIPTION: "Self-Centering" hydraulic type with non-adjustable anchor ramps for each shoe. An eccentric adjusting cam is used for brake shoe adjustment.

BENDIX (LOCKHEED) SELF-CENTERING REAR BRAKE (FRONT SIMILAR EXCEPT HAND BRAKE PARTS OMITTED)

ADJUSTMENT: Before making adjustments, jack up all four wheels, check brake pedal clearance or free travel (see below), fully release hand brake and make certain that rear wheels are free, then adjust each wheel as follows:

Brake Shoe Adjustment (For Wear or New Linings):

►*CAUTION: Brake shoes must be "centralized" by several hard brake applications before adjusting.*

Eccentric Adjustment - Adjust eccentric for each brake shoe by turning eccentric up and out until brake shoe firmly applied and wheel is locked, then back eccentric off until wheel just rotates freely without drag. Shoe clearance will then be approximately .010".

Anchor Lip Adjustment - Pressure required to pull shoe outward from support plate should be 15 lbs. Measure with spring scale hooked in end of shoe. Adjust by bending anchor lip slightly toward brake support plate to obtain this 15 lb. coil spring pressure to hold shoes on support plate ledges.

Hand Brake Adjustment: Remove all slack from rear wheel brake cables as follows:

Nash Statesman - Pull hand brake handle "ON" exactly 3½" (measure from face of bracket to handle). At rear wheel cable equalizer, loosen forward nut, tighten rear nut on front cable fitting until rear brakes are fully applied, then tighten front nut to lock adjustment. Release hand lever and check rear wheels for freedom from drag.

1954 Rambler - Pull lever "ON" two notches, loosen front nut on adjusting rod at rear cable equalizer, tighten rear nut to remove all slack from cables, then tighten front nut to lock adjustment. Release hand lever and check rear wheels for freedom from drag.

Rambler - Pull hand brake lever to rear to provide 3½" clearance between hand brake lever handle and bracket. Tighten hand brake cables at equalizer to a point where rear brakes are fully applied.

Willys (Vehicles with cabl connected to r ar wh l service brakes) -Pull hand lever "on" three notches, loosen front nut on connecting link between intermediate lever on frame crossmember and rear cable equalizer, tighten rear nut on link until slight drag noted at each rear wheel, then tighten front nut to lock adjustment. Release hand lever and check for freedom of drag.

Willys (Vehicles using pr peller shaft m unted parking brakes). Fully release hand brake lever, check linkage for freedom from bind. Rotate brake drum so one pair of three sets of holes are over adjusting screws. Use tool or screwdriver to rotate each adjusting screw away from drive shaft until shoes are snug against drum, then back off each screw 7 notches for running clearance.

Brake Pedal Adjustment: Adjust master cylinder pushrod by loosening locknut and turning rod for following pedal travel with master cylinder piston and pushrod back against stop:

Brake Pedal Free Travel - Nash (All Models ¼-½", Rambler ¼-½", Willys ½" min.

BLEEDING BRAKE SYSTEM & OVERHAULING BRAKE UNITS: *See "Hydraulic Brake Servicing" in Brake Section of Manual.*

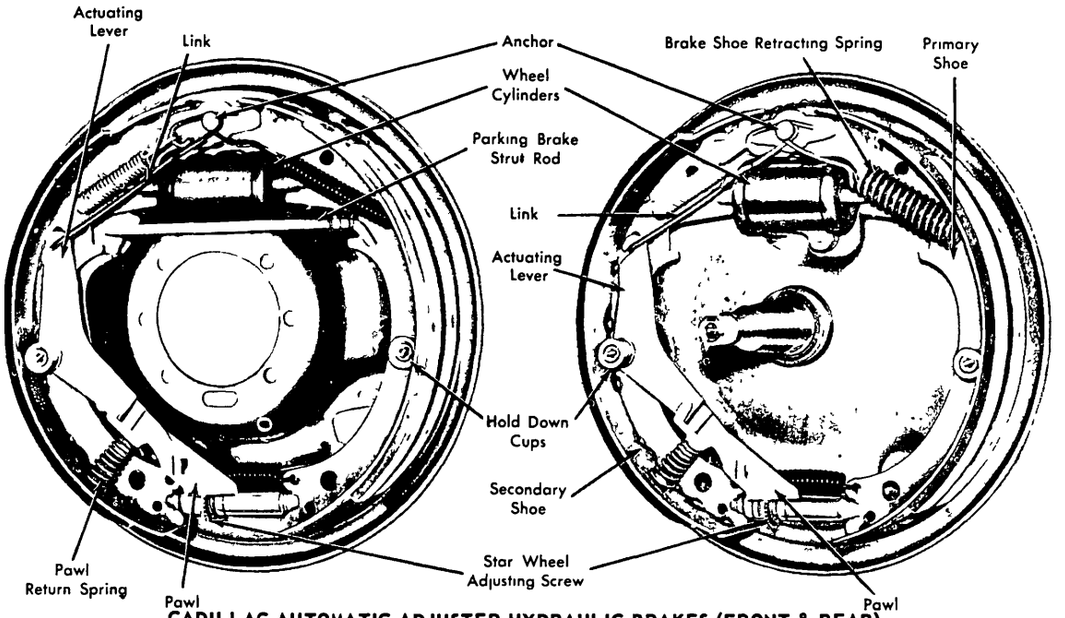
TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" in Brake Section of Manual.*

CADILLAC (BENDIX-MORAINE) AUTOMATIC ADJUSTER BRAKES

Cadillac (1960)

►CHANGES, CAUTIONS, CORRECTIONS

►*1960 CADILLAC BRAKE LINING & SECONDARY BRAKE SHOE RETRACTING SPRING PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* Primary brake shoe lining has been increased in length beginning with Engine No. 090000, and a new secondary shoe retracting spring which is attached to bottom hole in shoe is being used. *NOTE - This spring, Part No. 5460246, replaces the former spring which was attached to center hole in shoe.* A new brake shoe service replacement kit, Part No. 5460218 (standard lining), or Part No. 5460253 (high friction lining) may be used on cars before the above serial number if used with the new type retracting spring.



►*1960 CADILLAC BRAKE SHOE RETRACTING SPRING ATTACHING HOLE LOCATION NOTE:* Primary shoe retracting springs must be installed in lowest of the three holes in brake shoe. Secondary shoe retracting springs must be installed in center hole (early production), or in lowest hole (later production). *See "Production Change & Service Replacement Note" above.*

►*AUTOMATIC ADJUSTER & BRAKE BACKING PLATE SPECIAL LUBRICANT NOTE:* A special lubricant, Part No. 1098903, is available for service use to eliminate possibility of star wheel adjusters and automatic adjuster parts rusting and "freezing up", due to lack of lubrication.

DESCRIPTION: Hydraulic single anchor type brake (without eccentric). Brake shoe anchor pins are the adjustable type. The new "Moraine" automatic adjusting mechanism consists of a link, actuating lever, pawl, and pawl return spring.

OPERATION (AUTOMATIC ADJUSTER): The adjusters operate only when brakes are applied as car is moving in reverse. As the brake drums move rearward, the wrap around action of the brake shoes forces upper end of primary shoe against anchor pin and the secondary shoe away from anchor pin. The link which holds top of actuating lever stationary, forces actuating lever to pivot on secondary shoe. This pivoting action forces pawl downward against end of a tooth on the star wheel adjusting screw. If lining-to-drum clearances are correct, the downward movement will stop before star wheel is turned. If clearances are too wide, the secondary shoe will move outward and the pawl will move downward far enough to turn star wheel one notch and take up the adjustment.

ADJUSTMENTS: Brake Sho Adjustment - *NOTE - Adjustment should be required only after shoe relining, replacement or when length of star wheel has been changed.* With master cylinder properly filled with fluid, remove adjusting hole cover from brake backing plate (rear wheels), and from brake drum (front wheels), then make sure that parking brake cables and linkage (including levers on rear wheel secondary shoes) are free. Insert a .020" feeler gauge in slotted hole in brake drum and rotate drum until feeler gauge is between lower end of secondary shoe lining and drum, then tighten star wheel with feeler gauge in position, until a slight drag is felt on feeler gauge. *NOTE - To loosen an overtightened star wheel, it will be necessary to use a suitable tool inserted through the adjusting hole to disengage pawl from star wheel. On front wheels, use a hooked wire to pull forward, and on rear wheels, use a sharp pointed tool to push pawl outboard.* Rotate brake drum until slotted hole is at top of secondary shoe, and measure clearance with a feeler gauge between drum and lining. Clearance should be .010-.030" when clearance at bottom end is .020". If clearance is greater or less than specified, adjust anchor pin (see below). Install adjusting hole covers, install wheels, then drive car in reverse and apply brakes moderately five or six times while car is moving rearward. *NOTE - This action will operate automatic adjusters if any additional brake shoe expansion is required to bring brakes into proper adjustment.*

CADILLAC AUTOMATIC ADJUSTER HYDRAULIC BRAKES (FRONT & REAR)

Anchor Pin Adjustment: Loosen anchor pin locknut ½ turn. *NOTE - On front wheels it will be necessary to loosen backing plate upper mounting stud.* Tap anchor pin up, then all the way down to bottom of slot. Turn star wheel adjuster to expand brake shoes until drum cannot be turned in direction of forward rotation with a two foot bar placed between wheel stud nuts (this is equivalent to a two-hand drag with wheel and tire installed). Tap anchor upward lightly with a hammer. The drum should free up and rotate easily. Retighten star wheel and repeat tapping anchor nut until drum cannot be rotated without use of a two foot bar (this will cause brake shoes to centralize the anchor). Loosen star wheel until a .015" feeler gauge can be inserted between bottom of secondary lining and drum. Rotate drum forward until feeler is wedged between secondary shoe and drum, then turn drum back until feeler is at bottom of secondary lining. This clearance should be .015". If clearance is not as specified, adjust star wheel to obtain proper clearance. Check clearance between upper end of secondary shoe and drum. Clearance should be .010". If clearance not correct, tap anchor pin up if more than specified, or down if clearance is less than specified. A .010" feeler should clear all the way around, including primary shoe. *CAUTION - Do not attempt to set anchor to obtain a .010" and .015" clearance at primary sho* . Tighten front anchor locknut and backing plate upper mounting stud to 80-100 ft. lbs. Tighten rear anchor locknut to 100-120 ft. lbs. Recheck lining-to-drum clearance with a feeler gauge.

Parking Brake: With service brakes properly adjusted, lubricate parking brake linkage and check for free movement of cables in conduit and equalizer. Check rear relay lever spring and replace if necessary. Check for proper tension of intermediate cable by inserting 17/32" portion of Parking Brake Relay Lever Gauge, J-8530, in gap between relay lever and end of slot in frame. Adjust intermediate lever at front clevis until gauge is a slip fit. *NOTE - Make sure that equalizer nut has been backed off enough to leave cable slack when the 1 7/16" wide end of gauge is in place.* Tighten equalizer nut until a near lockup drag is obtained at rear wheels when they are turned by hand in a forward direction, then remove gauge from relay lever slot in frame side bar. *NOTE - After adjustments are completed, parking brake pedal should travel 2 1/8-2 3/8" with approximately 50 lbs. pressure on pedal.*

BRAKE SHOE REPLACEMENT: Removal - Remove wheel and brake drum assemblies, then loosen brake cable locknut on equalizer. Disconnect secondary and primary shoe retracting spring and remove primary shoe hold-down cups and spring, pin, and secondary hold-down cup and spring assembly, pin, and sleeve. *CAUTION - Hold-down cup and spring are an assembly on secondary shoe and are painted blue. On primary shoes, spring and cup are separate and the spring is painted red. Cups and springs are not interchangeable with previous models.* Remove pawl return spring, pawl, and actuating lever, then spread primary and secondary shoes to disengage shoes from wheel cylinder piston rods, and rotate complete assembly until link disengages from anchor pin. Remove star wheel adjuster, connecting spring, actuator link and secondary shoe retracting spring from shoe assembly. Clean brake backing plate and all brake parts. *CAUTION - Handle all brake parts with clean hands to prevent "grab" or "pull" when brakes are reassembled.*

CONTINUED ON NEXT PAGE

CADILLAC (BENDIX-MORAINE) AUTOMATIC ADJUSTER BRAKES (C ntinu d)

Installati n: Tighten backing plate bolts to 35-40 ft. lbs. (rear wheels), 80-100 ft. lbs. (front wheels). Lubricate all points of contact between brake shoe and other brake parts. Position brake shoes and hook the connecting spring between primary and secondary shoes, then install star wheel adjuster between shoes so that star wheel will line up with backing plate slot. *CAUTION - Make sure that star wheel adjusters with one identification groove in outer diameter (left hand threads) are installed on right side of car. Adjusters with two grooves (right hand threads) must be installed on left side of car. Before installing star wheel adjusters, make sure that small diameter thin washer is installed between end socket and larger diameter spring washer in adjuster assembly.* Install link actuating lever, pawl spring, and pawl, then install primary brake shoe hold-down pin, cups, and spring (spring is painted red), and secondary hold-down pin, cup and spring assembly, and sleeve (cup and spring assembly are painted blue). Install primary and secondary shoe retracting springs. *NOTE - Primary shoe retracting spring must be installed in lowest of three holes in brake shoe. Secondary shoe retracting spring must be installed in center hole (early production), or lowest hole (later production). See "Production Change & Service Replacement Note" above.* Loosen star wheel adjuster to permit installation of brake drums (adjust wheel bearings on front wheels). Adjust parking brake and service brakes.

PARKING BRAKE ASSEMBLY REPLACEMENT: Disconnect parking brake cable at bellcrank under car, then remove cable from clevis on parking brake assembly. Disconnect hose from vacuum diaphragm and remove two parking brake assembly to instrument panel mounting bolts. Remove parking brake assembly to cowl mounting bolts and remove assembly from car. To install, reverse removal procedures.

Vacuum Chamber Replacement: With parking brake assembly removed, straighten retaining tangs on vacuum chamber, then disconnect link from manual release lever and remove vacuum chamber. To install, reverse removal procedures.

BLEEDING BRAKE SYSTEM & OVERHAULING BRAKE UNITS: *See "Hydraulic Brake Servicing" in Brake Section of Manual.*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" in Brake Section of Manual.*

Rambler, Series 10 (1960) Ⓒ
Studebaker, All Models (1954-60)

NOTE - Other Rambler Models have Bendix Lockheed *Self-Centering brakes.*

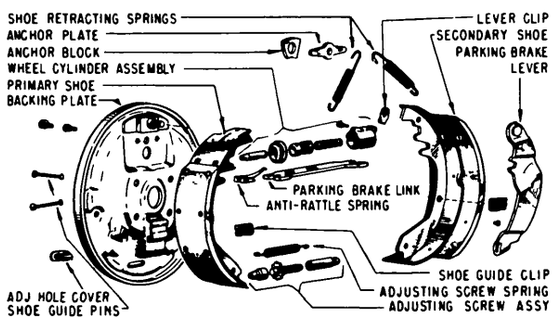
Ⓒ -Wagner Automatic Adjuster Brakes also used in 1959-60.

►CHANGES, CAUTIONS, CORRECTIONS

►*1954-55 LINING REPLACEMENT CAUTION:* On early production cars, some long and some short primary brake shoe linings were used on either front or rear wheel brakes. When it is necessary to replace primary shoe linings on a front or rear wheel, the other front or rear wheel should be inspected and the lining on the primary shoe also replaced, if necessary, to obtain same length primary lining on both front and rear wheels.

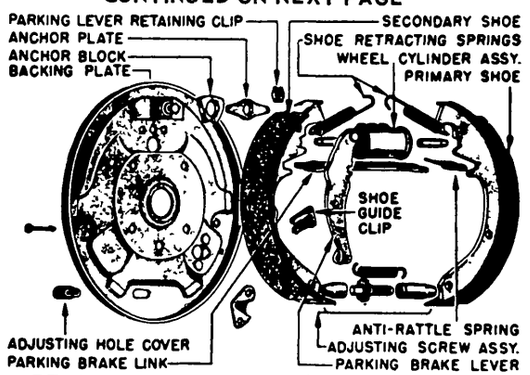
►*1954-55 PARKING BRAKE LEVER CLIP INSTALLATION CAUTION (To Prevent Breakage & Falling Off of Clip):* Above condition is partially result of assembling in reverse or incorrect order the springs that return the shoe assemblies. Assemble rear shoe return spring to the shoe and its spring retainer first, then assemble front shoe return spring.

►*1956-58 STUDEBAKER & PACKARD FRONT WHEEL SECONDARY LINING NOTE:* Front wheel secondary lining is ¼" thick (6 Cyl. Exc. Econ-O-Miler), 7/32" thick (V8 Models) (3/16" thick on all other shoes), and is pre-ground off-center at the factory to eliminate back squeal. This lining is applied to the full length of the shoe and is marked "Secondary" and "Top" and should be installed as marked.



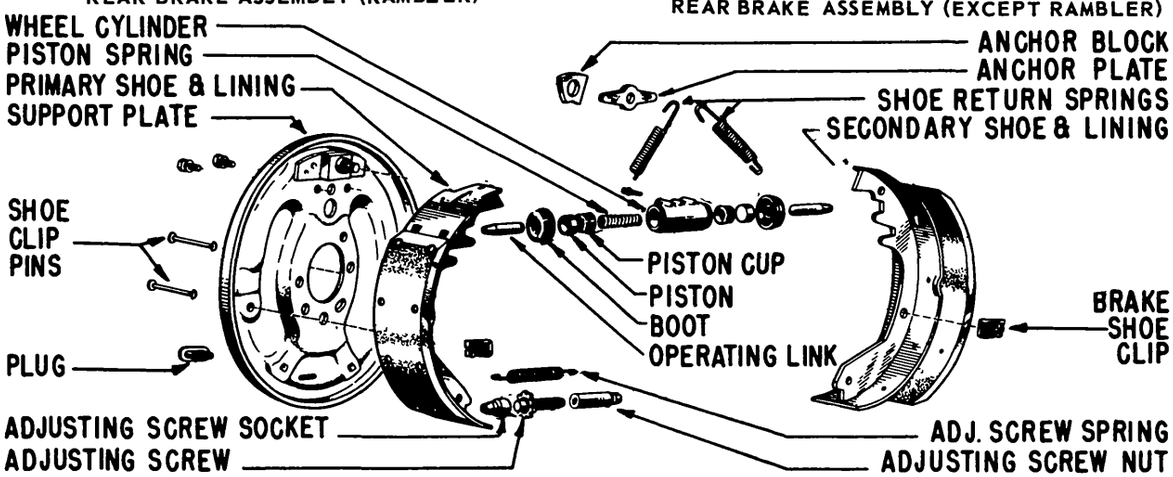
►*1960 RAMBLER "POPPING" & "SNAPPING" AT FRONT BRAKES (DURING BRAKE APPLICATION) CORRECTION:* **This condition may be due to tool marks remaining in brake shoe contact area of drum. To correct, remove tool marks with abrasive cloth or buffing stone.**

DESCRIPTION: Wagner Lockheed Hydraulic self-centering and self-energizing type (with Bendix type brake shoe assemblies). Brakes are not self adjusting, and new adjustment procedure is required. New self-centering device used.



Rambler Rear Brake Cylinder - Single piston type, mounted on backing plate, linked to primary shoe.

Self-centering Device—The upper (anchor pin end of each brake shoe rests against a wedge-shaped anchor block which is mounted on fixed brake anchor pin (shoes do not contact anchor pin directly) so that the shoes are free to move radially. The wide edge of the



CONTINUED ON NEXT PAGE

REAR BRAKE ASSEMBLY (RAMBLER)

REAR BRAKE ASSEMBLY (EXCEPT RAMBLER)

FRONT BRAKE ASSEMBLY (INCLUDING RAMBLER)

WAGNER (LOCKHEED) SELF-CENTERING (C nt.)

anchor block is toward the top. When the brakes are applied, the lining surface pressure tends to force the shoe to adjust its position on the block and center itself in the drum. This centering action takes place on light, or heavy brake application and is continuous with drum expansion. The anchor plate aids in keeping the shoes properly aligned at the self-centering block.

Adjusting D vic —Consists of a "star wheel" adjusting screw and stud assembly mounted between the lower ends of the two brake shoes (similar to Bendix Duo-servo brake shoe assemblies). Adjusting screw spring serves a dual purpose, holding the shoes against notches of adjusting screw, and binding against ratchet on screw to serve as a screw lock.

ADJUSTMENTS: Place car on stands so that all four wheels are free. Check master cylinder and see that fluid level is ½" below top of cylinder. Place parking brake handle in fully released position. Adjust as follows:

Rambler Brake P dal Fr Travel Adjustment: Adjust the brake pedal play ¼" to ½" by rotating the master cylinder piston pushrod to brake pedal attaching eccentric bolt.

Studebaker & Packard Brake P dal Free Travel Adjustm nt: Loosen locknut on brake pedal-to-master cylinder rod, turn master cylinder rod until free travel is ¼" —3/8" (Manual brakes), or 1/8" — ¼" (Power brakes).

Brak Sh Adjustment: Remove adjusting hole cover from backing plate, insert screwdriver or special adjusting tool through adjusting hole and turn adjusting screw to expand shoes until drum is just locked (pivot tool on edge of slot, move handle upward to expand shoes). Then back off the adjusting screw 10 notches (Rambler), 8 notches or clicks (Others) move if necessary until drum is free of any drag. Replace adjusting hole cover, adjust parking brake.

Parking Brake Adjustment: Rambler (Hand Operated Type). Pull handle back to give 3½" clearance between handle and mounting bracket. Tighten cable at equalizer until brakes are fully applied.

Rambler (Foot Operated Type) - With lever in fully released position, adjust rear cable at equalizer so wheels will turn without drag.

Studebaker & Packard - Set control handle four notches from the fully released position. Adjust rear wheel cables at equalizer on frame side rail by backing off front nut and tightening rear nut until all slack is removed from cables and a heavy drag noted when rotating rear wheels by hand. Tighten front adjusting nut. Release control handle fully and see that wheels are free of any drag.

RELINING BRAKES: *See Replacement Caution above.*

BRAKE SHOE REMOVAL & INSTALLATION:

Removal: Install wheel cylinder clamp to prevent hydraulic system leakage. Unhook the two shoe return springs at anchor. On rear brakes, swing the hand brake lever on the secondary shoe toward the axle to slacken cable. Lift cable from lever slot. Compress and remove hold-down spring clip on each shoe. Spread shoes and lift off brake support plate. On rear brakes, remove parking brake link and anti-rattle spring. Separate shoes by removing star wheel adjusting assembly and spring. On rear brakes, pull clip from parking brake lever mounted on secondary shoe and remove lever from shoe. Anchor plate and anchor block may now be lifted from anchor pin.

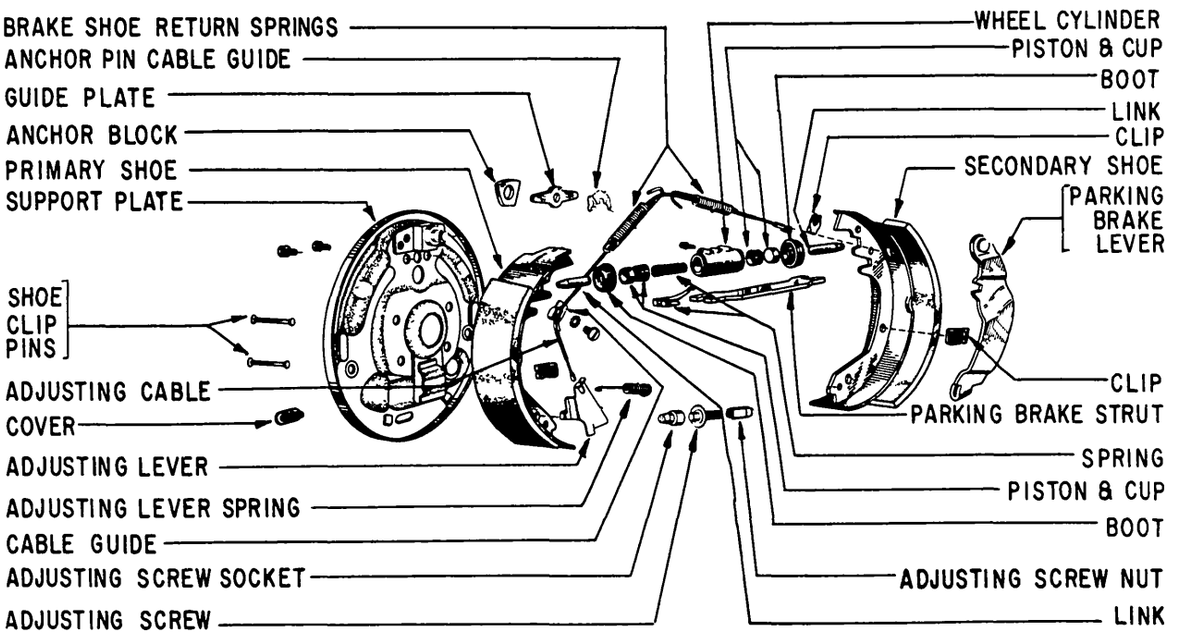
Installation: Reverse removal procedure. *NOTE* - On Studebaker Taxi and all 8 cylinder models, the parking brake lever is mounted on inner side of rear shoe. On Studebaker 6 cylinder models and all Rambler models, the parking brake lever is mounted on outside of shoe.

BLEEDING BRAKE SYSTEM & OVERHAULING OF MASTER CYLINDER & WHEEL CYLINDERS: *See "Hydraulic Brake Servicing" in Brake Section of Manual and note the following: CAUTION* - To bleed power brakes, engine must be stopped and no vacuum in power brake system. *NOTE* - On Studebaker equipped with power brake and/or hill holder, these units must be bled before the rest of the system.

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting".*

WAGNER AUTOMATIC ADJUSTER HYDRAULIC BRAKES

Rambl r, Seri s 01, 10 (1959)
Rambl r, S ri s 10 (1960)



►CHANGES, CAUTIONS, CORRECTIONS

►*1960 RAMBLER SERIES 6010 (& Series 5901, 5910) AUTOMATIC ADJUSTING BRAKE ADJUSTING CABLE WEAR CORRECTION:* If excessive wear is indicated on the adjusting cables at cable guides, install Brake Cable Package, Part No. 3209514 which consists of brake cable assemblies, right and left hand cable guides, special lubricant, and an instruction sheet. The new cable guides have been reworked for smoother operation.

►*1960 RAMBLER SERIES 6010 AUTOMATIC BRAKE ADJUSTER PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* Starting with Car Code No. 20328 an improved automatic adjusting brake became effective in production. The adjuster unit is similar to that previously used, however, special procedures are required for installation of brake shoe return springs and for anchor pin cable guide. See "Brake Shoe Replacement" below.

DESCRIPTION: Hydraulic, self-centering and self-energizing type with Bendix type brake shoe assemblies similar in design to Wagner (Lockheed) Self-Centering Brakes and incorporating an automatic adjuster to maintain proper lining to drum clearance. The automatic adjuster uses movement of the front (primary) shoe during brake applications to turn brake ad-

CONTINUED ON NEXT PAGE

WAGNER AUTOMATIC ADJUSTER BRAKE ASSEMBLY (REAR SHOWN - FRONT SIMILAR)

WAGNER AUTOMATIC ADJUSTER HYDRAULIC BRAKES (Con..)

justing star wheel a small amount as determined by lining wear. The adjuster consists of an adjusting lever, cable guide and an adjusting cable.

OPERATION: After lining wears enough to require adjustment, the adjusting cable will lift adjusting lever into position to engage with next tooth of star wheel when the brakes are applied. When brake is released, shoes return to the brake shoe anchor. This action will repeat on subsequent brake applications, if necessary, until shoe-to-lining clearance is reduced to a point where shoe movement is not enough to cause cable to lift lever to next tooth. The automatic adjuster is located on the front shoe (primary), and the adjusting action, when required, occurs when applying brakes in either forward or reverse motion.

ADJUSTMENT: Place car on stands so that all four wheels are free. Check master cylinder and see that fluid is ½" below top of cylinder. Place parking brake handle in fully released position, then adjust as follows:

Brak Pedal Free Travel Adjustment: ¼" to ½" free travel required. To adjust, rotate master cylinder pushrod-to-brake pedal attaching eccentric bolt.

Brak Shoe Adjustment: Adjustment not normally required, however, if a manual adjustment is necessary (after installation of new lining or shoes), proceed as follows: Remove access hole cover and use a screwdriver to rotate star wheel. To tighten, rotate backing plate side of star wheel toward axle. To back off star wheel, it may be necessary to insert a second tool, past the star wheel, to force automatic adjusting lever off of star wheel. Back off star wheel to eliminate drag.

Parking Brake (Foot Operated Lever): With lever in fully released position, adjust rear cable at equalizer so wheels will turn without drag.

BRAKE SHOE REPLACEMENT: *See "Wagner (Lockheed) Self-Centering" and note the following:*

Automatic Adjuster (Early Type Before Car Code No. 20328): Install adjuster cable guide on primary shoe but do not tighten cable guide screw at this time. Position adjuster lever fitting into large hole near end of primary shoe rib, then connect adjuster lever spring between secondary shoe rib (small hole) and slot in lever. Thread cable through shoe hold-down spring coils and over cable guide at anchor pin, hooking eye end of cable over secondary shoe return spring hook. Route cable around guide and with a screwdriver, swivel lever upward and engage barrel fitting end of cable in lever slide. *CAUTION - At time brake is assembled, the upper end of primary shoe return spring must be installed on top of secondary spring for proper cable alignment.* With brake in released position, push primary shoe cable guide outward pulling cable taut until bottom edge of adjusting lever is engaging star wheel tooth and parallel to star wheel shank. Tighten cable guide screw, then test action by pulling cable.

Automatic Adjuster (Later Typ Aft r Car Code No. 20328): After brake shoes, adjusting screws and adjusting lever have been installed, install the RED secondary shoe return spring with long hook end flat against shoe guide plate. The BLUE primary spring is installed **last** with short hook end flat against shoe table when hooked on tab of primary shoe. Slip anchor pin cable guide down on anchor pin and thread the cable and tubing through return springs from secondary shoe pin cable guide, through the primary spring, over the cable guide, and secure the pellet in slot of adjusting lever. With shoes centered on backing plate, adjust shoe cable guide so that the adjusting lever, which engages star wheel teeth, is on the centerline to 1/16" above centerline of adjusting screw. Be sure cable tubing is properly assembled in grooves of shoe cable guide and the anchor pin cable guide. Test ratchet action by pulling cable.

BLEEDING BRAKE SYSTEM & OVERHAULING OF MASTER CYLINDER & WHEEL CYLINDERS: *See "Hydraulic Brake Servicing" in Brak Section of Manual.*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" in Brake Section of Manual.*

CHRYSLER, DESOTO, DODGE, PLYMOUTH LOCKHEED "SAFEGUARD"

Chrysler 6, All Models (1954)
Chrysler 8, Exc. C53,59,66,70 Imperial (1954-55)
D Soto, All Models (1954-55)
Dodge, All Models (1954-55)
Dodge, 6 Cyl. D-62-1,2 (1956)
D dge, V8 D-63-1,2,3 (1956)
Plymouth, All Models (1954-55)
Plymouth, All 6 Cyl. & V8 Models (1956)

►CAUTIONS & CORRECTIONS

►*1954 POWER BRAKE CAUTION:* Vacu-Ease Power Unit Standard or Optional on Chrysler, DeSoto, Dodge, and later Plymouth cars. *See "Chrysler Vacu-Ease P w r Unit".*

►*1955 POWER BRAKE CAUTION:* Power Brake Standard on all Chrysler Models except C-67 (Windsor). Optional on Chrysler Windsor, DeSoto, Dodge, and Plymouth Models. *See "Chrysler & Imperial, DeSoto, Dodge, Plymouth Power Unit".*

►*1956 PLYMOUTH MASTER CYLINDER COVER BOLT CAUTION:* New replacement covers use ¼" shorter bolt with less body length. New bolt Part No. 1671571. DO NOT use original type cover bolt with new replacement covers (Bolt will bottom before cover tight).

►*BRAKE SQUEAL OR ABNORMAL LINING WEAR: Cam pins which are too high will cause brake shoe misalignment causing brake squeal and abnormal lining wear. Correct as follows:*

Cam Pin H ight Check & C rrecti n—To check cam pin height alter brake adjusting Tool MT-19-L and follow procedure below.

1) To alter Tool MT-19-L, drill and tap gauge holder and install wing type screw so that gauge can be secured to the bushing adapter.

2) (Front wheel). Place gauge on spindle with shoe removed and set gauge to height of wheel cylinder anchor lug. Check height of cam against this gauge setting. Cam pin should be equal or less than this reading.

3) (Rear wheel). Place gauge on axle with shoe removed and set gauge to height of rear wheel brake support. Check cam pin height against this setting. Cam pin should be equal or less this reading.

4) If cam pin height found to be more than height given above, raise brake shoe guide spring and file head of cam pin or replace pin with one of correct height.

Too Low Cam Pin Correction—To help raise cam pin without distorting brake shoe support plate, use stand-C-clamp and Tool C-3248.

Dimpling of Brake Shoe For Pin Clearance—Support shoe on piece of pipe or socket wrench at point to be dimpled. Place ball end of a ball-peen hammer on web directly over pipe or socket. Using second ball-peen hammer, strike first hammer a few sharp blows, until enough metal is raised on reverse side of shoe web to reduce clearance. To increase clearance, strike shoe from reverse side so as to form a slight cavity in web directly above face of cam pin.

Grooving Brake Lining (See CAUTION below)—If above procedures do not correct squeaks (make certain that brake drum dampener spring are in place also), lining can be grooved to secure more perfect contact between lining and drum as follows: Clamp brake shoe in vise, scribe diagonal line on face of lining beginning at point 7/8" in from side at one end and 7/8" from opposite side at opposite end. Cut groove approximately .050" wide (use two fine hacksaw blades clamped together in holder) completely through lining to face of of brake shoe.

►*CAUTION: Do not attempt to groove riveted lining or any of the edge-bonded, wire-backed, cycl -bonded linings.*

Slotting Brake Shoes (See CAUTION below)—If grooving does not correct squeaks, toe end of shoes can be slotted to depth of 1 3/8". Use hacksaw blade to cut web loose from shoe table (lining surface), cutting as close to table as possible.

►*CAUTION: Do not slot front brake shoes which have four 5/8" holes through the shoe table.*

DESCRIPTION: The "Safeguard" brake system consists of two-cylinder type hydraulic brake (front wheels), single double-acting cylinder type hydraulic brake (rear wheels):

Two-Cylinder (Front Wheel) Typ—Consists of two independent single-acting brake cylinders mounted on the backing plate, each cylinder actuating one brake shoe. Each cylinder is mounted on the anchor pin of the other shoe (top cylinder mounted on rear shoe anchor pin and actuates forward shoe, bottom cylinder mounted on forward shoe anchor pin and actuates rear shoes). All shoes are "primary" or self-energizing type.

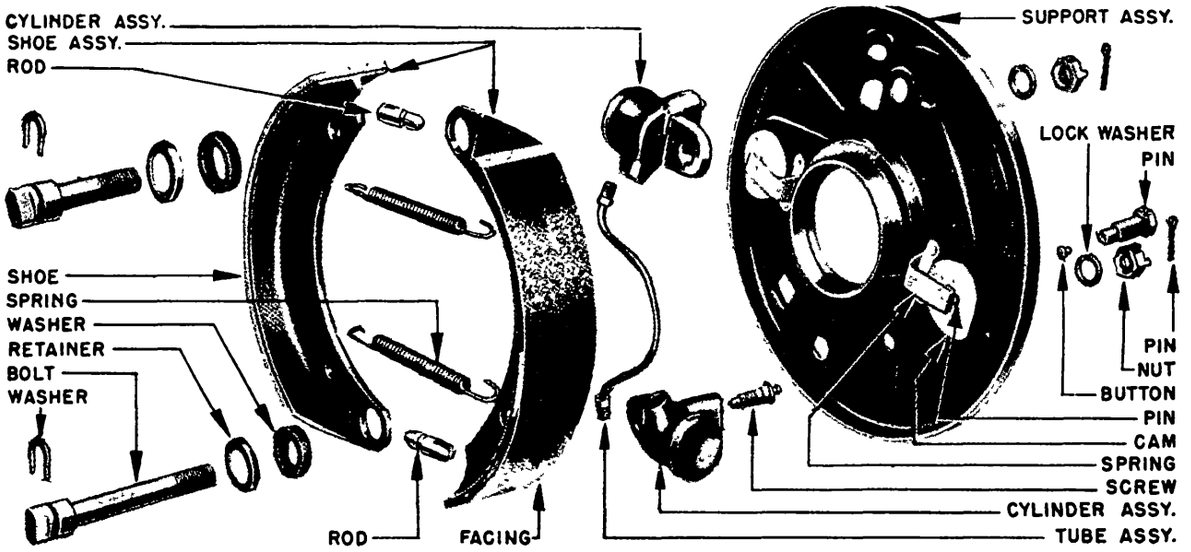
Single Cylinder (Rear Wheel) Type—Same as other "Lockheed Double Anchor Hydraulic" brake cylinders. Consists of single double-acting cylinder mounted at top of backing plate and actuating both brake shoes. Shoes are pivoted on anchors at bottom of backing plate.

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH LOCKHEED "SAFEGUARD" (Cont.)

►*CAUTION:* Before making any adjustment be sure anchor bolts are in correct position. Arrows must point away from the heels of shoes they control.

ADJUSTMENT: Before making adjustments, jack up all wheels, check brake pedal free travel (should be 1/8-1/4" to take up pushrod play) plus additional 5/8-3/4" (to close off master cylinder relief port) before brakes begin to be applied. Total pedal travel to apply brakes should be 1¾-2". If Minor Adjustment does not give correct pedal travel, or if relief port is cut off with less than ¾" pedal travel, check brake pedal free play



Brake Pedal Adjustment: Adjust master cylinder pushrod to obtain 1/8-1/4" (1954-55), 3/32-3/16" (1956) free play with master cylinder piston against stop. On 1955-56 Plymouth distance between brake pedal and pedal stop should be .015-.030", which will result in approximately 1/8" free play at pedal pad.

►*1955 POWER BRAKE NOTE:* Power Brake unit has built-in pedal return spring and a pedal return stop, and **require s n fre play adjustment.**

Minor Wear Adjustment: Turn adjusting cams(pull down on wrench handle) until shoe is locked against drum (Dodge), light drag (Plymouth). Back off cam just enough to remove all drag. Repeat adjustment for each shoe in all four wheels.

Major (New Lining) Adjustment: Use adjusting gauge MT-19-K or feeler gauges and cutaway drum and adjust eccentric and anchor pin for each shoe to obtain .006" clearance at both toe and heel, for all models.

►*CAUTION:* After adjusting brakes on one wheel, do not use same gauge setting for brakes on another wheel. Gauge must be reset according to inside diameter of brake drum of **each** wheel.

CHRYSLER "SAFEGUARD" FRONT (TWO CYL.) BRAKE ASSY.

Hand Brake Adjustment: Hand Brake is independent type mounted on driveshaft at rear of transmission. *See Car Model Pages and individual model Special Data Pages.*

BLEEDING BRAKES (With Integral Power Unit): With outlet line to wheel cylinders connected loosely, attach pressure bleeder to reservoir, open bleeder screw on top of master cylinder, bleed unit until free of air, close bleeder screw, continue bleeding until no bubbles appear at outlet connection, tighten connection. If pedal not firm, bleed all wheel cylinders as on standard manual brakes.

BLEEDING BRAKES (Manual Brakes & with "Bell ws" or "Piston" Power Units): *See "Hydraulic Brake Servicing"*

OVERHAULING BRAKE UNITS: *See "Hydraulic Brak Servicing"*

TROUBLE SHOOTING: *See "Hydraulic Brake Troubl Shooting"*

CHRYSLER, DE SOTO, DODGE & PLYMOUTH "CENTER PLANE" & "TOTAL CONTACT" BRAKES

Chrysler & Imperial (1956-59)
De Soto, All Models (1956-59) Ⓒ
Dodge 500 (1956)
Dodge, All Models (1957-59)
Plymouth, All Models (1957-59)

Ⓒ - Used on early cars. Later cars have "Three Platform" type brakes. See "Brake Identification Note"

►CHANGES, CAUTIONS, CORRECTIONS

►*1956 BRAKE "SQUEAK" CORRECTION:* To correct brake squeaks or other brake noises proceed as follows:

1) Torque axle housing to rear spring U-bolt nuts to a specified torque of 65-80 ft. lbs.

2) Inspect for out of round drums, distorted support plates, or loose anchor pins. To correct loose anchor pins, remove support plates, check alignment, place support plate with the pin resting in vise, repeen end of pin until it is tight.

3) Torque the five rear wheel brake support to axle bolt nuts to 35 ft. lbs. The four front wheel brake support bolt nuts must be torqued to 55 ft. lbs.

4) Brake shoe guide spring, Part No. 1484680, which is held in place by the retainer, Part No. 1486945, must be very tight against brake shoe and support. Loose guide springs should be bent to restore their tension. The retainer must not exceed specifications of 15/32", measured between inside ends.

►*REAR WHEEL REMOVAL CAUTION:* **Do not apply service brakes to hold shoes against drum while using wheel puller.** To hold hub and drum from turning while using wheel puller back off brake shoes from drum with adjusting cams. Apply hand brake and allow one rear wheel to remain on floor, or block wheel.

►*1958 DODGE & PLYMOUTH MASTER CYLINDER PRODUCTION CHANGE & FREEPLAY ADJUSTMENT NOTE:* Later cars have new master cylinder, Part No. 1829400 (Dodge), No. 1829401 (Plymouth), which incorporates a brake pedal stop and eliminates need for brake pedal freeplay adjustment. The brake pedal stop and return spring are eliminated. This results in a somewhat slower pedal return when brakes are released. *CAUTION* - Do not pull brake pedal to released position with more than 50 lbs. of force as this will cause deflection of piston stop and result in excess pedal travel before brakes apply.

►*1959 BRAKE IDENTIFICATION NOTE:* New "Three Platform" type brakes used in production on different cars at different times beginning in January 1959. Some early cars may have one type at front wheels the other type at rear wheels. *NOTE* - Depressions (for platforms) appear on back side of backing plate on "Three Platform" type. For "Three Platform" data, see "Three Platform Total Contact Brakes".

►*1959 PARTS NON-INTERCHANGEABILITY NOTE:* The following parts are the only ones that are interchangeable between the two types of brakes. 1) Brake Drums. 2) Brake Lining. 3) Rear wheel cylinder boots. 4) Front and rear wheel cylinder pushrods, pistons, expanders, and springs. 5) Front wheel cylinder connecting tube assembly.

►*1959 BRAKE LINING REPLACEMENT CAUTION:* Use only a lining set with same color identification as used on opposite wheel.

DESCRIPTION: These hydraulic brakes have two floating shoes mounted between two plates located on the center plane of the lining. On front wheel brakes, two single piston cylinders (single action) are attached to

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE & PLYMOUTH "CENTER PLANE" & "TOTAL CONTACT" BRAKES (Cont.)

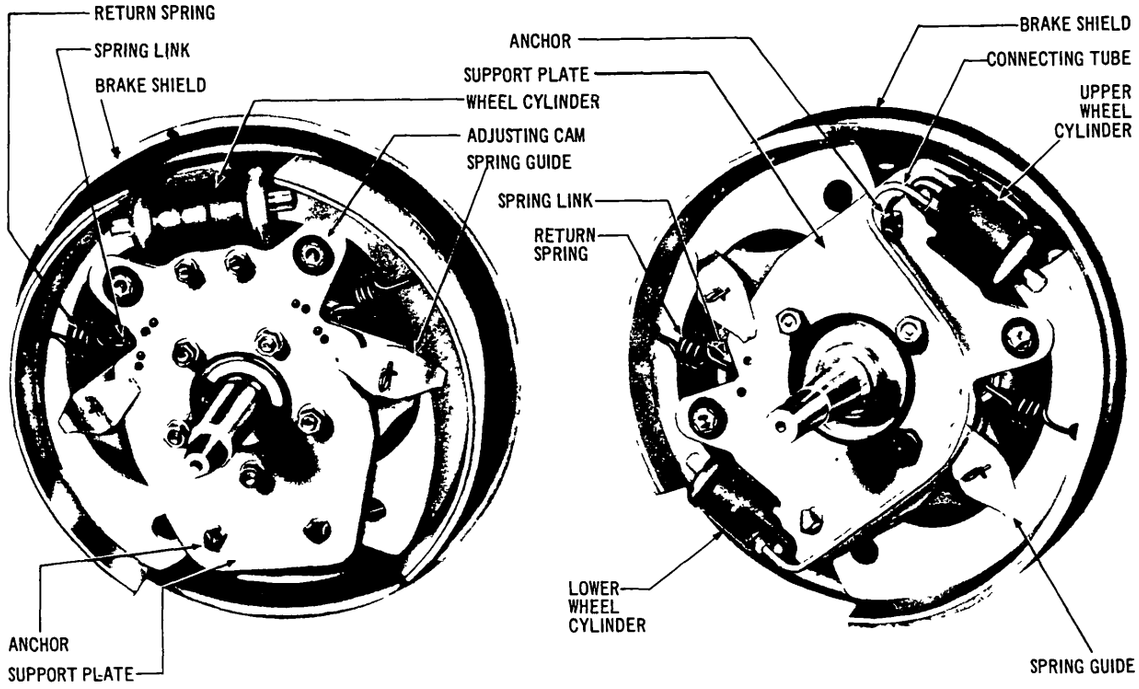
the support plate assembly, the upper cylinder actuating the front shoe, and the lower cylinder actuating the rear shoe. On rear wheel brakes, one double piston cylinder (double action) is attached to the top of the support plate assembly and actuates both brake shoes. An anchor pin in support plate assembly holds spring link in a fixed position at one end. The other end of link is positioned by brake shoe adjusting cam, providing a constant-loaded spring length. Side rattle and twisting of shoe is controlled by spring guide, which maintains a constant pressure against side of web of shoe holding shoe against support plate.

ADJUSTMENTS: Place car on stands, so that all four wheels are free. Check master cylinder and see that fluid level is not over ½" below top of cylinder. Place parking brake lever in fully released position.

Brake Pedal Adjustment: Release locknut on brake pedal to master cylinder pushrod and rotate rod to obtain specified clearance. *NOTE - Pedal adjustment not required on later Dodge & Plymouth cars. See "Production Change & Freeplay Note" above.*

Standard Brakes - 1/32-1/8" (Chrysler & DeSoto), 1/8-1/4" (Dodge & Plymouth, **early cars only**).

Power Brakes - 1/32-1/8" All Cars.



Front Wheel Adjustment: Turn each adjusting cam on both front shoes in the direction of FORWARD wheel rotation until lining is solid against drum and wheel is locked. Turn adjusting cams slowly in opposite direction (each cam a little at a time) until no drag is felt.

Rear Wheel Adjustment: Turn front shoe adjusting cam in direction of **forward** wheel rotation and rear shoe adjusting cam in direction of **reverse** wheel rotation until lining is solid against drum and wheel is locked. Turn adjusting cams slowly in opposite direction until no drag is felt.

►*RELINED OR NEW SHOE ADJUSTMENT NOTE* – Apply brake pedal prior to adjusting brakes to properly center shoes in brake drum and to assist in adjustment.

Hand Brake Adjustment: Hand Brake is independent type mounted on drive shaft at rear of transmission. *See Car Model Pages and individual model Special Data Pages.*

BLEEDING BRAKE SYSTEM: Use compressed air refiller, Tool C-3496 attached to master cylinder to keep master cylinder filled. Back off adjusting cams all the way, then starting with right rear wheel cylinder, attach bleeder hose, Tool C-650 to valve, with other end in jar partially filled with brake fluid. Bleed intermittently, opening and closing valve (at wheel cylinder) until fluid runs out of bleeder hose in a solid stream without bubbles. Repeat this operation on left rear wheel, right front wheel and finally left front wheel. At front wheels (with two cylinders), bleed lower cylinder first to force air out of connecting line to upper cylinder, then bleed upper cylinder. Repeat bleeding operation if brake action indicates air still in lines. Readjust cams after completing bleeding operation.

REAR WHEEL BRAKE **FRONT WHEEL BRAKE**

CENTER PLANE BRAKE ASSEMBLIES

BRAKE SHOE REPLACEMENT: Removal – 1) Remove wheel, hub and drum assembly using puller C-845 to remove drum assembly.

2) Insert wrench C-3462, in the inner support plate hole, with tool cam slot engaging the spring hook. Turn tool handle to disengage spring from spring link, and turn handle in opposite direction to release the spring. Remove both springs in this manner. *CAUTION* - Do not use brake spring pliers or damage to lining will result.

3) Turn brake shoe guide spring retainer 1/4 turn and remove (the lip on end of spring is for correct positioning on outer support assembly). Slide shoes from support assembly.

Installation: 1) Position brake shoe in support plate, (make sure that wheel cylinder pushrods properly engage toe end of shoes and that shoes are in alignment).

2) Check tension of springs which should be 70 lbs. plus or minus 5 lbs., installed length. This can be checked by hooking a scale at toe end of shoe and pulling shoe away from wheel cylinder. Scale should read 35-45 lbs., before contact is broken between web of shoe and wheel cylinder.

LINING REPLACEMENT: Drum diameter should not exceed .004" out of round at any point. Grind lining to specified clearance of .010"-.024" below drum diameter.

WHEEL CYLINDER & SUPPORT PLATE: Removal & Disassembly 1) Disconnect flexible brake hose at wheel cylinder (upper cylinder on front), and remove wheel cylinder mounting screws and lockwashers at rear of brake shield.

2) Remove support plate mounting bolts and remove support plate with wheel cylinders and connector tube attached.

3) With assembly on bench, remove cylinder connector tube and wheel cylinders.

Assembly & Installation: 1) Assemble wheel cylinders on support plate. (Install connector tube on front assembly).

2) Position support plate on brake shield and install cylinder mounting screws and lockwasners, but do not tighten.

3) Install support plate bolts, lockwashers and nuts. Tighten to 35 ft. lbs. and cylinder mounting screws to 20 ft. lbs.

WHEEL CYLINDER OVERHAUL: Wheel cylinder pistons that are badly scored or corroded should be replaced. Use new piston cups when reconditioning cylinders. Cylinder walls that have light scratches, or show signs or corrosion, can usually be cleaned up with crocus cloth. Cylinders that have deep scratches or scoring, may be honed using Tool C-3080. Diameter of cylinder bore should not be increased more than .002". If a cylinder does not clean up at .002" it should be replaced *(NOTE* - Black stains on cylinder walls are caused by piston cups and will do no harm).

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" in Manual.*

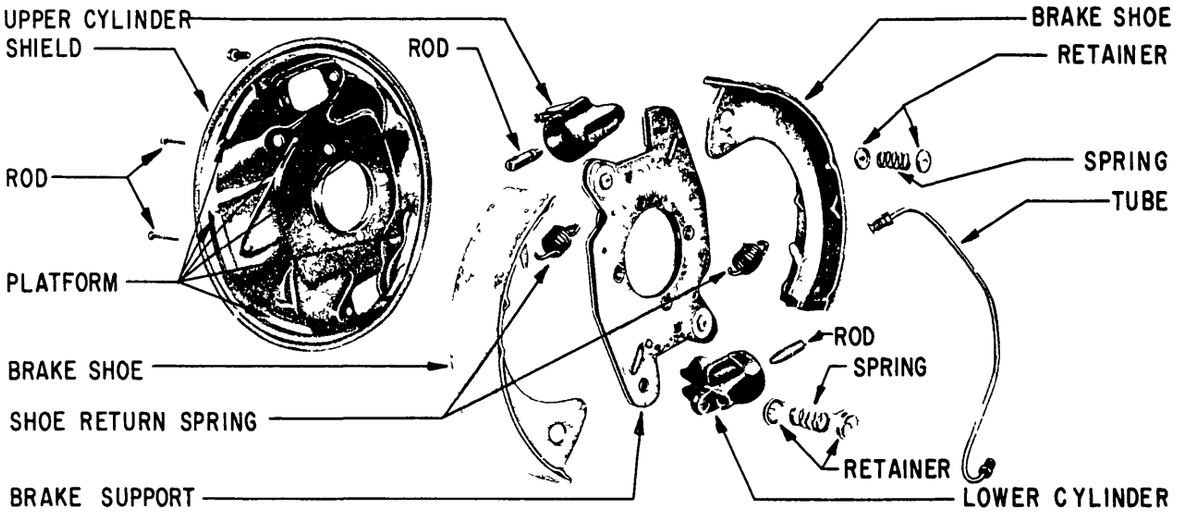
CHRYSLER, DE SOTO, DODGE, PLYMOUTH "THREE PLATFORM" TOTAL CONTACT BRAKES

Chrysler & Imperial (1959-60) ℂ
D Soto (1959-60) ℂ
Dodge (1959-60) ℂ
Plymouth (1959-60) ℂ
ℂ - Early 1959 Cars have "Center Plane" type brakes. See "Brake Identification Note" below.

►CHANGES, CAUTIONS, CORRECTIONS

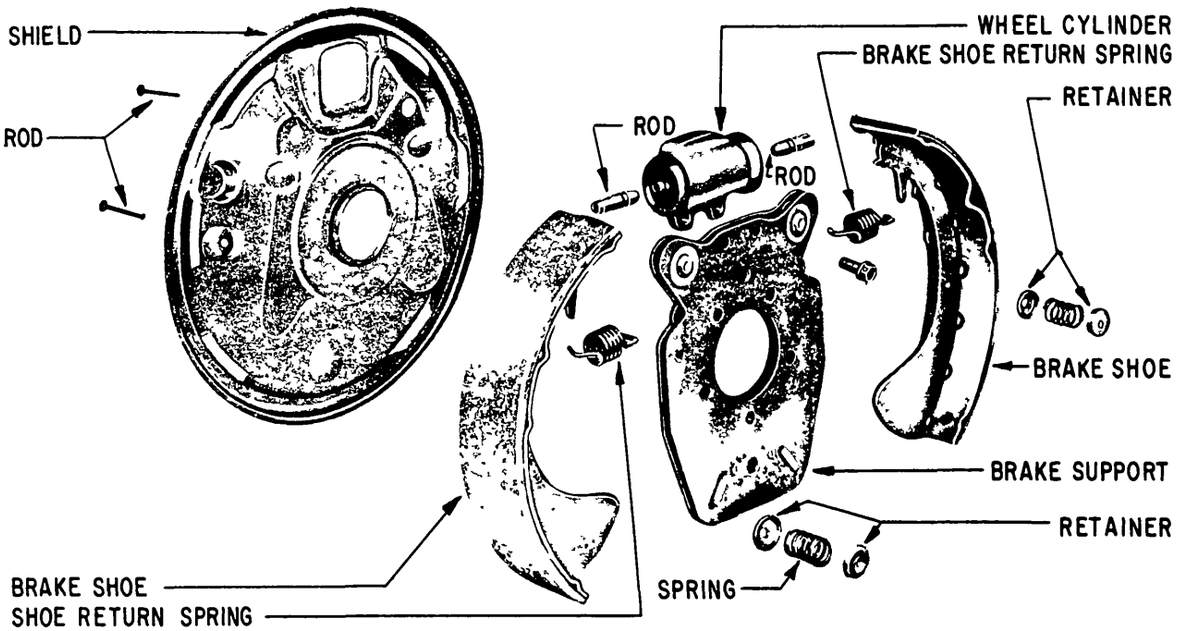
►*1959 BRAKE IDENTIFICATION NOTE:* New "Three Platform" type brakes used in production on different cars at different times beginning in January 1959. Some early cars may have one type at front wheels the other type at rear wheels. *NOTE* - Depressions (for platforms) appear on back side of backing plate on "Three Platform" type. *For "Center Plane" data, see "Center Plane Total Contact Brakes".*

►*1959 PARTS INTERCHANGEABILITY NOTE:* The following parts are the only ones that are interchangeable between the two types of brakes. 1) Brake Drums. 2) Brake Linings. 3) Rear wheel cylinder boots. 4) Front and rear wheel cylinder pushrods, pistons, expanders, and springs. 5) Front wheel cylinder connecting tube assembly.



►*1959-60 BRAKE, DRAG, PULL OR TOO FREQUENT BRAKE ADJUSTMENT CORRECTION:* This condition may result from burrs or sharp edges on brake shoe table loops and/or dust shield platforms. To correct, remove drums and brake shoe assemblies and remove any burrs or paint build-up on dust shield platforms. Lubricate all platforms with a thin film of MoPar "door ease" or Lubriplate. Carefully remove all sharp edges on shoe loop with a file or scraper. *CAUTION - Remove sufficient material to smooth loop edges only.* Reinstall brakes, retainers and return springs. Check brake shoe return spring tension by attaching a spring scale at toe of shoe and pull shoe away from wheel cylinder. Shoe should begin to move away from wheel cylinder pushrod at 45-55 lbs. If more than 55 lbs. is required to move shoe check for cause of drag. If less than 45 lbs. is required to move shoe, replace with new return springs.

►*1960 BRAKE SHOE NOISE OR BRAKE HOWL CORRECTION:* Noise or howl may be caused by loose brake shoe anchors in support plate. Check by removing brake drum and inspect anchors for tightness. If anchors are loose, they may be tightened by peening over the ends, or by a pair of tack welds with an arc welder. *CAUTION - Do not use acetylene weld.* If anchors are tightened by peening, be sure to support the anchor while peening to prevent damage to support plate.



►*1960 DODGE BRAKE HOWL AT LOW SPEEDS:* This condition may be encountered on suburban models and may be corrected by installing rear spring insulators, Part No. 1731797 (upper), 1731798 (lower). If correction is not satisfactory inspect brakes, particularly for loose anchors (see above).

►*BRAKE LINING REPLACEMENT CAUTION:* Use only a lining set with same color identification as used on opposite wheel.

►*REAR WHEEL REMOVAL CAUTION:* **Do not apply service brakes to hold shoes against drum while using wheel puller.** To hold hub and drum from turning while using wheel puller, back off brake shoes from drum with adjusting cams. Apply hand brake and allow one rear wheel to remain on floor, or block wheel in suitable manner.

THREE PLATFORM TOTAL CONTACT BRAKE ASSEMBLY - FRONT WHEELS

THREE PLATFORM TOTAL CONTACT BRAKE ASSEMBLY - REAR WHEELS

DESCRIPTION: These hydraulic brakes have three raised platforms (for each shoe) pressed into dust shield and three contact loops on each brake shoe so that shoe will ride on the platforms. An additional loop in brake shoe is for the attachment of return spring. The platforms act as guides to maintain proper shoe alignment and to reduce vibration and noise. Return spring is hooked in center of brake shoe eliminating need for flat guide springs. On front wheel brakes, two single piston cylinders (single action)

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "THREE PLATFORM" TOTAL CONTACT BRAKES (Cont.)

are attached to support plate assembly, the upper cylinder actuating the front shoe and the lower cylinder actuating the rear shoe. On rear wheel brakes one double piston cylinder (double action) is attached to top of support plate assembly and actuates both brake shoes. An anchor pin in support plate assembly holds spring link in fixed position at one end. The other end of link is positioned by brake shoe adjusting cam, providing constant-loaded spring length. Side rattle and twisting of shoe is controlled by shoe retainer spring which maintains a constant pressure against platforms.

ADJUSTMENTS: Place car on stands, so that all four wheels are free. Check master cylinder and see that fluid level is not over ½" below top of cylinder. Place parking brake lever in fully released position.

Brake Pedal Adjustment: *NOTE - Pedal freeplay adjustment not required on cars with manual brakes. The master cylinder has a fluted dust boot and retainer and the retainer acts as a master cylinder piston stop. Pedal return spring and pedal stop have been eliminated. DO NOT pull on brake pedal and lever as master cylinder pushrod may be pulled from master cylinder.*

Power Brakes - Freeplay should be 1/16"-1/8" (all cars). To adjust, release locknut on brake pedal to master cylinder pushrod and rotate pushrod to obtain specified clearance. Insert a screwdriver blade between rubber collar of trigger pivot and rear side of elongated hole in power brake lever, forcing them apart. *See "Power Brakes".*

Front Wheel Adjustment: Turn each adjusting cam on both front shoes in the direction of FORWARD wheel rotation until lining is solid against drum and wheel is locked. Turn adjusting cams slowly in opposite direction (each cam a little at a time) until no drag is felt.

Rear Wheel Adjustment: Turn front shoe adjusting cam in direction of **forward** wheel rotation and rear shoe adjusting cam in direction of **reverse** wheel rotation until lining is solid against drum and wheel is locked. Turn adjusting cams slowly in opposite direction until no drag is felt.

►*RELINED OR NEW SHOE ADJUSTMENT NOTE:* Apply brake pedal prior to adjusting brakes to properly center shoes in brake drum and to assist in adjustment.

Hand Brake Adjustment: Hand Brake is independent type mounted on drive shaft at rear of transmission. *See Car Model Pages and individual model Special Data Pages.*

BLEEDING BRAKE SYSTEM: Use compressed air refiller, Tool C-3496 attached to master cylinder to keep master cylinder filled. Back off adjusting cams all the way, then starting with right rear wheel cylinder, attach bleeder hose, Tool C-650 to valve, with other end in jar partially filled with brake fluid. Bleed intermittently, opening and closing valve (at wheel cylinder) until fluid runs out of bleeder hose in a solid stream without bubbles. Repeat this operation on left rear wheel, right front wheel and finally left front wheel. At front wheels (with two cylinders), bleed lower cylinder first to force air out of connecting line to upper cylinder, then bleed upper cylinder. Repeat bleeding operation if brake action indicates air still in lines. Readjust cams after completing bleeding operation.

BRAKE SHOE REPLACEMENT: Removal - 1) Remove wheel, hub and drum assembly using puller C-845 to remove drum assembly.

2) Insert wrench C-3462, in the inner support plate hole, with tool cam slot engaging the spring hook. Turn tool handle to disengage spring from spring link, and turn handle in opposite direction to release the spring. Remove both springs in this manner. *CAUTION* - Do not use brake spring pliers or damage to lining will result.

3) Turn brake shoe guide spring retainer 1/4 turn and remove (the lip on end of spring is for correct positioning on outer support assembly). Slide shoes from support assembly.

Installation: 1) Position brake shoe in support plate, (make sure that wheel cylinder pushrods properly engage toe end of shoes and that shoes are in alignment), **2) Check tension of springs by hooking a spring scale at toe end of shoe and pulling shoe away from wheel cylinder. Scale should read 45-55 lbs. (early 1959 cars with first type spring, was 35-45 lbs.), to move shoe off wheel cylinder. If more than 55 lbs. required to move shoe, check for cause of drag. If less than 45 lbs. is required to move shoe, replace springs.**

LINING REPLACEMENT: Drum diameter should not exceed .004" out of round at any point. Grind lining to specified clearance of .010"-.024" below drum diameter.

►*BRAKE BACKING PLATE & BRAKE SHOE LOOP NOTE:* Platforms for each shoe must be uniform in height and flatness (use surface gauge to check) and mating loops on brake shoes must be uniform and smooth. Replace backing plate when platform heights vary more than .010".

WHEEL CYLINDER & SUPPORT PLATE: Removal & Disassembly - 1) Disconnect flexible brake hose at wheel cylinder (upper cylinder on front), and remove wheel cylinder mounting screws and lockwashers at rear of brake shield.

2) Remove support plate mounting bolts and remove support plate with wheel cylinders and connector tube attached.

3) With assembly on bench, remove cylinder connector tube and wheel cylinders.

Assembly & Installation: 1) Assemble wheel cylinders on support plate (Install connector tube on front assembly).

2) Position support plate on brake shield and install cylinder mounting screws and lockwashers, but do not tighten.

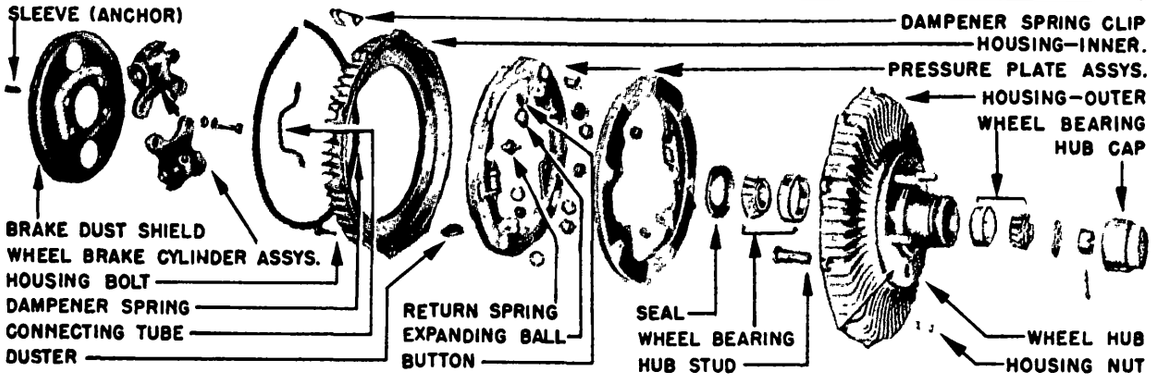
3) Install support plate bolts, lockwashers and nuts. Tighten to 35 ft. lbs. and cylinder mounting screws to 20 ft. lbs.

WHEEL CYLINDER OVERHAUL: Wheel cylinder pistons that are badly scored or corroded should be replaced. Use new piston cups when reconditioning cylinders. Cylinder walls that have light scratches, or show signs of corrosion, can usually be cleaned up with crocus cloth. Cylinders that have deep scratches or scoring, may be honed using Tool C-3080. Diameter of cylinder bore should not be increased more than .002". If a cylinder does not clean up at .002" it should be replaced (*NOTE* - Black stains on cylinder walls are caused by piston cups and will do no harm).

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" in Manual.*

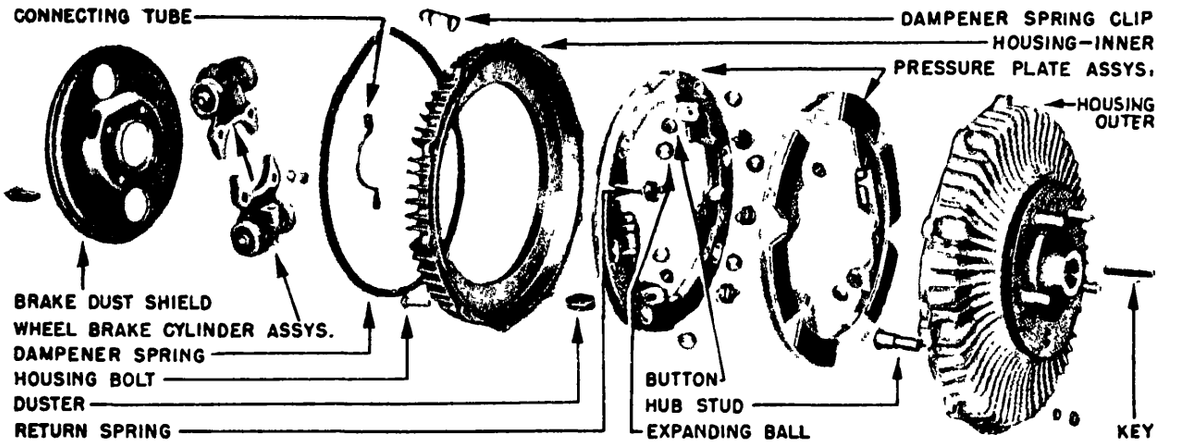
CHRYSLER DISC BRAKE (WITHOUT SPIDER)

Chrysler Crown Imperial C59,66,70 (1954-55)



►*1954 ADJUSTER ROD PRODUCTION & CLEARANCE CHANGE:* The automatic adjuster rod-to-outer pressure plate clearance has been increased from .005-.010" to .015-.020". The rod length is reduced from 2.445-2.446" to 2.435-2.436".

DESCRIPTION: The Chrysler Disc Brake is hydraulically operated, self-energizing. The brake assembly, enclosed in a rotating housing, utilizes two lined pressure plates in the form of annular rings which move apart, contacting the inner surfaces of the rotating housing, when brake application is made. The housing is split and held together by 10 bolts around the outside edge. The pressure plate assembly rests on a duster located at the bottom of each brake housing. Automatic brake adjusters are built into the assembly. Brake lining segments are used, bonded to the outer surface of each pressure plate. Two hydraulic cylinders, mounted on steering knuckle in front and on the rear axle flange, move push rods operating against bosses on the pressure plates.



OPERATION: When the outer plate is rotated with respect to inner plate through action of the wheel cylinder push rods, steel balls between the pressure plates are forced up on ramps located on the inside surfaces of the plates. The movement of the balls up the ramps forces the pressure plates apart and contact is made between the lining and the inner surfaces of the brake housing.

Whe l Brake Automatic Adjuster: The self-adjusting mechanism automatically compensates for lining wear. Desired clearance is maintained, at all times, between pressure plates and brake housing. Two identical automatic adjusters are mounted, one on each plate, operating at 180° to each other, and are identical in operation for either front or rear brakes. Two lugs are provided on each of the two pressure plates, placed to straddle automatic adjusters. Each self-adjusting unit comprises a bracket (integral to the individual pressure plate) with two guide flanges, rod, lubricating washer, 11 steel adjuster balls, adjuster washer, bushing and sleeve. When brakes are applied, outer plate is rotated with respect to inner plate and lug contacts adjuster rod. If brake linings are new, linings contact housing before rod is pushed forward. If linings are worn, lug pushes adjuster rod through bracket guide flanges until linings contact brake housing and relative rotation of outer plate stops. When brakes are released, brake return springs cause outer plate to tend to return to former position. When lug on opposite end of rod comes into contact with the rod, the locking action (provided by the automatic adjuster) prevents adjuster rod from being pushed back, and outer plate cannot return completely to former position. Because difference between length of rod and distance between finished surfaces of lugs has been calculated to provide desired clearance between linings and housing when brakes are released, proper clearance is maintained regardless of wear on linings.

ADJUSTMENT: Self-adjusters used and no service adjustment to compensate for lining wear required during useful life of linings. Manufacturer recommends that plate assemblies be switched from front to rear every 15,000 miles to obtain maximum brake lining life.

FRONT BRAKE

REAR BRAKE

CHRYSLER DISC BRAKE ASSY. (WITHOUT SPIDER)

Brake Pedal: ⅛-¼" free travel. Adjust by loosening locknut on master cylinder end of pedal rod and turning large adjusting nut.

Parking (Hand) Brake: Independent, internal expanding type. *See Car Model pages for adjustment data.*

REPAIR DATA: *CAUTION—Inner and outer housings are balanced as an assembly and should be assembled accordingly. Further, do not install left pressure plates or wheel cylinders on right side or vice versa.*

Wheel Brake Cylinders: Front brake cylinders are 1¼" diameter and rear cylinders are 1" diameter. *NOTE—Because there is no direct connection between pressure plate and wheel cylinders, brake assemblies can be removed as a unit from car without opening housings or disrupting hydraulic system.* Normal inspection or replacement of front brake cylinder parts does not require removal of cylinder from steering knuckle.

Bleeding Brakes: *CAUTION—Do not use fluid from pressure type filler or a container that has been open more than a few hours.* Connect hoses at each wheel position. Fill master cylinder with a bottle type filler with fluid from newly opened, sealed container. Bleed lower cylinder on each wheel first—do by hand, not with pressure bleeder—then refill master cylinder reservoir after bleeding each cylinder. After bleeding all four lower wheel cylinders, bleed four upper cylinders.

►*CAUTION—A short section of bleeder hose should be placed over bleeder valve before opening bleeder. If not done, it is possible for fluid to seep inside housings, contaminating linings.* Bleed only one cylinder at a time. Be very sure all air is expelled from brake lines and wheel cylinders.

►*CAUTION—After brakes are thoroughly bled, brake pedal will be very low. Drive car forward very slowly depressing and releasing brake pedal slowly as car moves forward. After pedal has built up to approximately ¾ of its full height recheck fluid level in master cylinder. Car should then be driven five miles applying brakes at intervals. There should be no brake dive or pulling to one side when brakes are applied.*

CONTINUED ON NEXT PAGE

CHRYSLER DISC BRAKE (WITHOUT SPIDER) C nt.

Brake Lining: Molded asbestos, segment type lining used, Cyclebonded. Thickness 5/32". Clearance between lining and housing—Self-adjusting.

►***CAUTION—With new linings, erratic operation may result for a few miles of operation. Normal brake operation should occur after not more than 25 or 30 miles of driving.***

DISASSEMBLY: ***NOTE—Brake assemblies can be removed from car as a unit without opening housings or disrupting hydraulic system.***

Front Disc Brake: Remove hub cap, cotter key spindle nut, then complete brake assembly from steering knuckle. Transfer assembly to clean bench with assembly resting on outer hub section. Remove damper spring and clips, then housing attaching bolts. Check to see that there are cast cut-outs in each housing (these cut-outs must be matched on reassembly). If no cut-outs, mark. Separate inner and outer housings by tapping lightly, at one of the attaching bolt hole flanges, with fibrenose hammer. Remove pressure plate assemblies ***(do not lose duster at bottom of each housing).*** Place brake pressure plate assembly on clean surface or cloth (to avoid contamination of lining segments).

Rear Disc Brake: Remove cotter pin, axle nut and washer. Install Wheel Puller C-844, remove brake housing, pressure plate and hub assembly. Remove axle shaft key, dampener spring and clips, then remove housing attaching bolts (Check to see that there are cast cut-outs in each housing. These cut-outs must be matched on reassembly. If no cut-outs, mark). Separate inner and outer housings by tapping lightly, at one of attaching bolt hole flanges, with fibrenose hammer. Remove outer brake housing pressure plate and hub assembly ***(do not lose duster at bottom of each housing).*** Place brake pressure plate assembly on clean surface or cloth (to avoid contamination of lining segments).

Inner & Outer Pressure Plates: Release automatic adjusters. (By inserting a thin shank screwdriver between release sleeve in automatic adjuster and adjuster guide, then twisting screwdriver, pressure plates will snap back into fully released position). Remove four pressure plate retaining springs ("V" slot cut into one side of a screwdriver will facilitate removal). Separate discs.

Automatic Adjuster: Push or pull rod out by hand (moves in one direction only). Slide sleeve out from between pressure plate lugs. ***CAUTION—Hold finger over each end of sleeve during removal so contents are not lost.***

INSPECTION & CLEANING: Proceed as follows:

Wheel Cylinders: Examine bores and pistons for score marks or pits. Replace if necessary. Replace piston cups with new ones. ***CAUTION—Only front wheel cylinder piston cups Part No. 77526 bearing letters "AA" or "DT" should be used. Do not use cups bearing letters "BQ".*** Reassemble wheel cylinders using new dust boots.

Automatic Self-Adjusters: ***NOTE—It is not necessary to remove adjusters unless new pressure plates to be installed.*** Inspect adjuster rods to determine if correct rods are present and for scoring or brinelling from adjuster balls.

Adjuster Rod Identification—Rod has radial groove machined at one end. Length of rod is 2.435-2.436".

Scoring & Brinelling Inspection—Insert small screwdriver between adjuster bushing and bracket to release adjuster balls. Move rod to one end. Wipe off pin surface and inspect. Move pin to opposite extreme to inspect other end. Pin should be free of scoring or brinelling. ***Do not lubricate automatic adjusters.***

Brake Housings: Inspect for cracks. If found, replace. Light radial marks on surface of housing may be polished out with fine emery cloth. Similarly with bluish heat spots. ***NOTE—Do not mate 40-fin housing with 60-fin housing on opposite side of car.***

Pressure Plate Expanding Balls: Should be clean and free of flat spots, rust or nicks. Dull coating on balls is not reason for rejection. This is protective coating and does not affect operation. Rusted balls may be cleaned by placing in cloth bag partially filled with sand and shaking vigorously.

Master Cylinder: Remove from car. Clean and inspect for pits and scores. Replace if found. Reassemble using new valve and cups. ***CAUTION—Assemble from push rod end to prevent damage to valve seal ring. Be sure valve seal ring in position before installing valve and spring. Note carefully that valve seal, Part No. 1318447 seats directly on the end plug and the valve, Part No. 1318446, is held against this seal by return spring.***

REASSEMBLY: ***NOTE—Inner and outer housings are balanced as an assembly and should be assembled accordingly. Do not install left pressure plates or wheel cylinders on right side or vice versa.***

Disc Brake: Release both automatic adjusters, install brake pressure plate assembly in outer housing half, place duster in "down" position at bottom of pressure plate. Install inner housing and line up aligning marks (cut-outs) in each housing, tighten 10 attaching bolts, install dampener spring and clips. Apply pressure on push rods of wheel cylinders to facilitate pressure plate installation. ***NOTE—It may be necessary to open bleeder screws to allow pistons to retract. Manufacturer recommends that bleeder screws be tightened with pistons retracted. This holds pistons in position desired until pressure plates installed.*** With pressure plates in down position and duster in position, proceed as follows:

Front Brake—Position housing pressure plate and hub assembly, then slip complete assembly over steering knuckle and wheel cylinders making sure plates are piloted properly over wheel cylinders to avoid damaging or dislocating boots Install outer bearing, spacer washer, nut, and adjust wheel bearings. Install cotter key, hub cap, and wheel assembly.

Rear Brake—Mount housing and pressure plate assembly to axle shaft making sure that plates are piloted properly over wheel cylinders to avoid damaging or dislocating boots. Position key-way, install key, washer and nut. Tighten axle shaft nut to 140 ft. lbs. minimum, then install cotter key, tire, and wheel assembly.

Inner and Outer Pressure Plates: With automatic adjuster properly installed on each of pressure plates, place the six steel pressure expanding balls (7/8" diameter) in the six ramps. Place outer plate in position on inner plate. Automatic adjuster rods must also be centered so that operating lugs on the matching plate will straddle rods. Install four pressure plate retaining springs.

Automatic Adjuster: Make dummy shaft out of round stock 1/4" in diameter and 3/4" long, chamfered on one end. Place adjuster sleeve (slotted end down) upright on finger and insert dummy shaft (chamfered end up) in sleeve. Position bushing over dummy shaft. Hold shaft and bushing in position with large end of common paper clip. Install 11 adjuster balls. Tap lightly to position balls, install adjuster washer, position adjuster spring in sleeve. Holding thumb over spring, carefully remove paper clip. Continue to hold pressure on spring-compress sufficiently to slide sleeve into position on bracket. NOTE—Sleeve is grooved and pressure plate stepped so that installation can only be made right way. Align sleeve assembly so that dummy shaft is in line with holes in pressure plate. Insert adjuster rod in pressure plate hole and force dummy shaft out. Center adjuster rod as nearly as possible. Install lubricating washer on adjuster rod at stepped end of adjuster bracket.

CHEVROLET-BENDIX HYDRAULIC

Chevrolet Pass. Cars, All Models (1954-60)
Chevrolet Corvair (1960)
Chevrolet Corvette (1954-60)
Chevrolet ½ Ton Trucks (1954-60)
Chevrolet Trucks, All Models (Exc. 1½ & 2-Ton Rear Brakes (1954-60) ©
© - For 1½ & 2-Ton Rear Brakes, see Chevrolet "Twinplex Brakes".

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 CHEVROLET BRAKE DESIGN CHANGE (Pass. Cars & ½ Ton Trucks):* Brake anchor adjustment has been eliminated. To compensate for this adjustment, brake shoes have been made .057-.087" smaller in diameter than drum. When a bench mounted shoe grinder is used, shoes should be ground to **undersizes** indicated above. When spindle mounted type shoe grinder is used, shoes should be ground to **actual drum diameter.**

►*PASS. CARS & HALF TON BRAKE SHOE GRINDING CAUTION:* If bench type grinder used, grind shoes to .057-.087" smaller diameter than drum size. If spindle type grinder used, grind shoe to drum diameter.

►*POWER BRAKE NOTE:* Bendix Power Unit optional on passenger cars. Hydrovac Power Unit optional on trucks. *See "Bendix Power Unit" or "Hydrovac Power Unit" under Power Brakes.*

►*BRAKE DRUM REPLACEMENT CAUTION:* Use suitable volatile non-toxic greaseless type solvent to clean oil from braking surface of drum before drum is installed.

►*METALLIC BRAKE LINING CAUTION:* This special purpose optional type lining may be used with the old standard drums provided surface of drum is smooth. Service adjustments are the same as for standard brakes except as noted in data below.

►*BRAKE SHOE ANCHOR PIN INSTALLATION CAUTION:* Tighten brake shoe anchor pins to torque indicated in table below.

Anchor Pin Tightening Torque

Model	Ft. Lbs.
Pass. Car (Exc. Corvair)	65
Corvair (Front)	60-85
Corvair (Rear)	100-126
Truck, 10 Series (Front & Rear)	100-125
Truck, 20, 30 Series (Front & Rear)	150-175
Truck, Others (Front)	150-175

►*METALLIC LINING SERVICE NOTES:* When servicing the special purpose optional type lining it is important that the items below are followed:

Pull Back Spring Installation - Heat resistant type springs used as follows; PINK pull back springs must be used with front primary shoes and both rear shoes. YELLOW pull back springs must be used with front secondary shoes. Use GREEN hold down springs on all eight shoes. Paint on the springs will become blistered and burnt in operation but does **not** indicate that springs have been excessively hot.

Hold Down Spring Cup Installation - Install large hold down spring cup against web and small cup at outer end of hold down spring.

Drum Replacement - Blue heat discoloration is normal and drum should not be replaced if surface of drum is smooth.

DESCRIPTION: Duo-Servo, single anchor, hydraulic type without eccentric adjustment.

ADJUSTMENT: Adjustments are made differently for wear (Minor Adjustment) and for new lining or shoe assemblies (Major Adjustment). Major adjustment should also be made whenever a minor adjustment is not satisfactory.

Brake Pedal Adjustment (1954): 7/16" (Cars), 13/16" (Trucks except Fwd. Control), 1" (Fwd. Control) between top of pedal arm and toe pan with brakes released and master cylinder pushrod against its stop. Adjust as follows:

Pass. Cars—Loosen check nut on eccentric pedal bolt, turn bolt, tighten check nut to 20-25 ft. lbs.

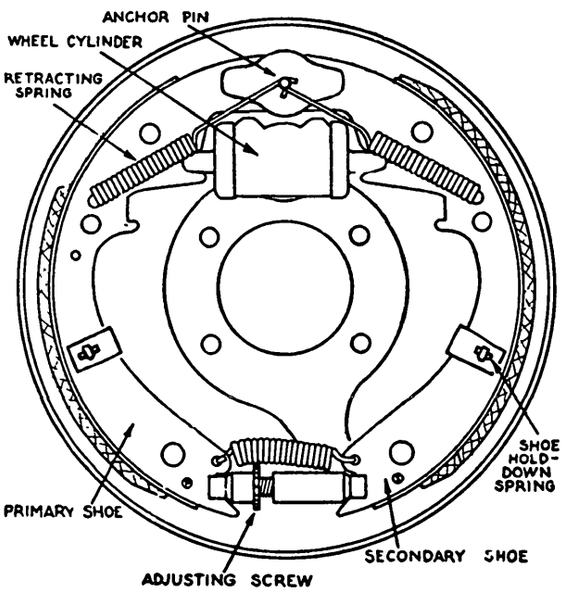
►*CAUTION:* If correct 7/16" clearance cannot be secured by turning eccentric bolt, adjust by installing shims under front or rear master cylinder bolts.

Trucks (Exc. Fwd. Control)—Loosen locknut at pushrod clevis, turn pushrod, tighten locknut against clevis. *NOTE*—Hold pushrod while tightening locknut.

Trucks (Fwd. Control)—Remove floor pan and cotter and clevis pins from upper end of brake pedal lever rod. Adjust for proper clearance, install upper end to brake pedal, inserting clevis and cotter pins, replace pan.

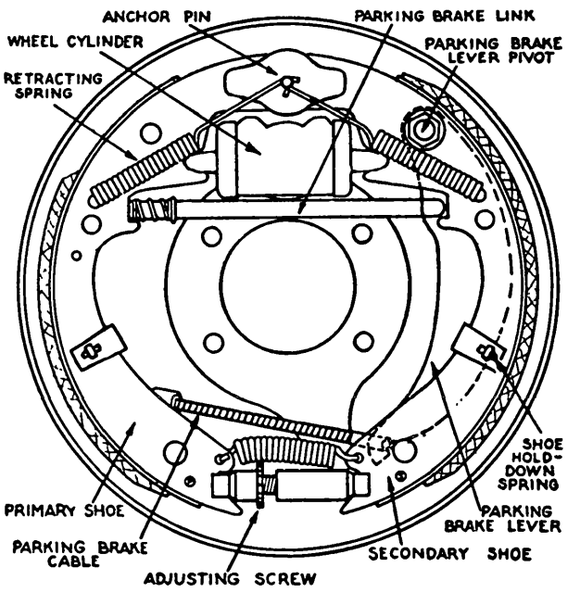
Brake Pedal Adjustment (1955-60): Before adjusting make sure pedal returns to fully released position freely, with no binding, and that pedal retracting spring has not lost its tension.

Passenger Cars - 1/16" (1955-56), 1/8-3/8" (1957-60) pedal movement before contact of pushrod and main cylinder piston. To adjust loosen check nut on clevis. Turn pushrod in proper direction to secure adjustment. Tighten check nut on clevis.



Trucks (Fwd. Contr. 1954-59) - ¾" clearance between top of pedal arm and toe board. To adjust, loosen check nut at rear of clevis on main cylinder pushrod. Turn main cylinder pushrod by knurled portion ahead of boot, in proper direction to secure desired clearance. Tighten check nut.

Trucks (Others 1954-59) - 1¾" (Low Cab Forward), 11/16" (Others except Fwd. Control), clearance between upper corner of lower pedal arm and seal around upper pedal arm in toe board. To adjust, remove cotter pin and loosen castle nut on adjusting bolt, then rotate adjusting bolt in required direction to obtain desired clearance, tighten adjusting bolt nut, recheck clearance, reinstall cotter pin in adjusting bolt nut.



Trucks (1960) - **Rotate eccentric bolt or adjust pushrod so that pedal free travel measured at center of pedal pad is 1/8". *NOTE* - Stop light switch should be adjusted to make electrical contact at approximately 13/16" pedal travel.**

Minor Adjustment (For Wear): Jack all wheels clear of floor. On passenger cars, loosen check nut at brake cable equalizer to remove tension from brake cable. On trucks, disassemble clevis of parking brake pull rod. On all cars and trucks, remove adjusting hole covers from flange plates. Expand brake shoes by turning adjusting screw with Tool J-4707 until a light uniform drag is felt on brake drum (move outer end of tool toward center of wheel to expand shoes). On passenger cars and ½ Ton truck, turn adjusting screw in opposite direction 12 notches (supersedes previous specification of 7 notches), Corvair rear wheels 15 notches, to relieve brake drag. On all other Truck Models, back off

CONTINUED ON NEXT PAGE

FRONT BRAKE ASSY.

REAR BRAKE ASSY.

CHEVROLET-BENDIX HYDRAULIC

(C ntinu d)

adjusting screw just enough to eliminate drag (not to exceed 7 notches). Replace adjusting hole covers, then reconnect and adjust parking brake.

Major Adjustment (New or Relined Shoes) (1954-Early 1955 Pass. Cars; 1954-59 Trucks): Loosen anchor pin nut just enough so that pin can be rotated (*CAUTION*–if nut loosened too much, brake springs will tilt anchor pin). With tool J-4707, turn brake adjusting screw to expand brake shoes until a heavy drag is felt on the drum. Tap brake flange plate and turn eccentric pin in direction tending to reduce drag by allowing shoes to center in drum. If drag on drum is reduced, expand shoes by tightening adjusting screw several more notches and again turn eccentric anchor pin while tapping brake flange plate Repeat this operation until drag remains constant. Then tighten anchor pin nut to 60-85 ft lbs (Pass , ½ & ¾ Ton Front & Rear Brakes, 1 Ton Front Brakes), 125-150 ft lbs (1 Ton Rear Brakes, 1½ & 2 Ton Front Brakes). Back off adjusting screw just enough to eliminate drag but **not more than 7 notches.** If more than 7 notches required to eliminate drag, repeat adjustment procedure. Adjust parking brake (below). *NOTE*–If heavy intermittent drag noted, brake drums should be rebored and new linings installed

HAND (PARKING) BRAKE ADJUSTMENT: Passenger cars and ½ & ¾ Ton Trucks adjusted differently 1,1½,2 and some ¾ Ton Trucks have propeller shaft mounted parking brakes. *CAUTION - Service brakes must be properly adjusted before making parking brake adjustment*

1954 MODELS

Adjustment (Pass. Cars): Pull hand brake handle "on" 7 clicks of the pawls (*CAUTION*–this is not 7 notches). Loosen both check nuts at forward end of each wheel cable, tighten front nuts against clevis plates to tighten each cable until moderate drag secured at each rear wheel, tighten rear nuts securely to lock adjustment. Set hand brake handle 2 clicks from fully released position. No brake drag should be noticed.

Adjustment (½ Ton Truck): Set parking brake foot pedal in fully released position Adjust pedal pull rod clevis so that clearance between brake cross-shaft and frame crossmember at center is 1/8" Depress foot pedal 1½". Pull each wheel cable forward out of the conduit as far as possible, loosen locknut and adjust clevis on forward end of cable until hole in clevis lines up with hole in cross-shaft outer lever, connect cables Depress foot pedal until heavy drag noted, check both wheels for equal drag readjust wheel cable clevis as necessary Release foot pedal, check clearance between release rod handle and rod support bracket This clearance should be ½", correct by adjusting handle

Adjustment (¾ & 1 T n Truck): With parking brake pedal pedal in fully released position, adjust brake pedal pull rod clevis for correct position of cross-shaft outer levers Center of hole in end of lever should be to rear of center-line of cross-shaft the following distance on each model: 29/32" (¾ Ton exc Fwd Control), ¾" (¾ Ton Fwd. Control), 11/32" (1 Ton exc. Fwd. Control), 19/32" (1 Ton Fwd Control) Then adjust wheel cables in same manner as on Half-Ton (above).

Adjustment (1½ & 2 Ton Truck): Parking brake is independent type on propeller shaft at rear of transmission *See "Chevrolet Twinplex" Brakes*

1955-59 MODELS

Adjustment (Pass. Cars & Corvette): Jack up both rear wheels Check clearance between idler lever and mounting bracket at equalizer (approximavely ¼") To correct, disconnect equalizer, tighten check nuts on forward cable. On Pass Cars, remove floor cover and push in parking brake pedal to 6½" from toe pan On Corvette, pull hand brake out 7 "clicks" (not same as notches) Loosen forward check nuts on equalizer and tighten rear one until there is a slight drag on both rear wheels when rotating drums Tighten check nuts securely Set parking lever back to 2 clicks from full release position, no brake shoe drag should be felt

Adjustment (½ & ¾ Ton Trucks using cable connected to rear wheel service brakes) Jack up both rear wheels. If clevis of parking brake disassembled, place parking brake lever in fully released position, then install clevis to brake pull rod to obtain a dimension of 1 7/16' from end of pull rod to centerline of clevis. With parking brake lever in fully released position and pull back spring in place, adjust parking brake cable at idler lever to obtain a clearance of ¼' between idler lever and rear end of slot in guide. Pull hand brake lever back four notches from fully released position. Pull cables out of conduits by hand as far as possible and assemble cables into idler lever links Tighten nuts and locknuts. Pull back hand lever until heavy drag is felt at one wheel. Check other wheel for drag, and if any difference is noted, loosen tight wheel until equal drag is obtained With hand lever pulled out nine notches both rear wheels should be locked so that they cannot be turned by hand. *NOTE*–If more than nine notches are required to lock brakes, check service brake adjustment

1960 MODELS

Adjustment (Chevrolet Pass. Cars): *NOTE - A spring loaded pedal return and a ratcheting mechanism to permit a second stroke of pedal, if necessary, is used. Parking brake application is assured even if rear service brakes are out of adjustment. Pedal returns to normal position after each stroke and will not indicate brake application. When parking brake is applied, the release handle will "pop out" about 2", indicating that brakes are applied. If more than two strokes are required to set brakes, check both service and parking brake adjustment.* Raise rear wheels and adjust front cable by means of the cinch bolts at front of idler lever extension so that forward edge of idler lever is approximately ½" behind rear edge of frame bracket. *NOTE - Pull r arward on idl r l v r wh n making this adjustment to assur that all slack is r moved from front cabl .* Press parking brake pedal until release lever just reaches limit of its travel (approximately 3 clicks). Adjust equalizer bolt nuts until moderate shoe drag is felt at rear wheels, then release brake and check that brakes are not dragging. Parking brake should be as tight as possible without having any significant drag upon release.

Adjustment (Corvair): Raise rear of car and pull parking brake lever up 3 notches from fully released position Loosen forward check nut on equalizer and tighten the rear one until a heavy drag is felt at rear wheels. Tighten check nuts securely. Fully release parking brake and rotate rear wheels, no drag should be felt

Adjustment (Corvette): Pull hand brake out 7 clicks of pawl (not notches). Looseh check nuts on cable ends, then turn forward check nuts against clevis plates until a moderate drag is felt when rotating brake drums. Tighten check nuts and set parking brake lever to 2 notches from full released position. No drag should be felt.

Adjustment (Trucks Without Pr p ll r Shaft Parking Brake): With service brakes properly adjusted, raise rear wheels and apply parking brake lever 4 notches from a fully released position. Loosen jam nut on threaded rod at end of forward cable. *NOTE - If threaded rod length is insuffici nt to obtain adjustm nt, move primary lever to n xt supplem ntal adjusting hole toward rear of truck.* Tighten rear nut on threaded rod until a light drag is felt at rear wheels, then tighten jam nut and lower truck to floor. Test parking brake.

1954-60 MODELS

Adjustment (¾ & 1 Ton Trucks using pr p ller shaft mounted parking brakes): Adjust clevis on brake pull rod so distance from end of rod to center line of clevis pin hole is 1 7/16" Place the hand brake lever in fully released notch of ratchet sector Loosen locknut on brake pull rod Remove cotter pin from clevis pin holding brake rod to brake cam (leave loose) Set brake cam rest flat on upper brake band bracket Back off adjusting nuts (at lower end of spring) and adjusting nut at top of adjusting bolt (bolt joins lower part of band to bracket) (*CAUTION* - Do not remove nuts, loosen only) Remove lock wire from anchor screw. Adjust anchor screw until there is 010- 015" clearance between lining and drum at anchor screw Tighten adjusting bolt (bolt without spring) until there is .020" clearance between drum and lower end of brake band Tighten locknut Tighten adjusting nut at lower end of spring until there is 020" clearance between drum and upper end of brake band Tighten locknut Adjust brake pull rod so clevis pin can be installed while brake cam rests flat on upper brake band bracket Install cotter pin in clevis pin of brake pull rod and tighten locknut on brake pull rod Install lock wire on anchor screw Recheck all points of facing for correct clearances

Adjustment (1½ & 2 Ton Trucks): Use independent type *See "Chevrolet Twinplex" for data.*

BLEEDING BRAKE SYSTEM: *S "Hydraulic Brak S rvicing" for compl t data.*

TROUBLE SHOOTING: *S "Hydraulic Brak Troubl Sho ting" for c mpl t data.*

Form 49 A

CHEVROLET TRUCK TWINPLEX

Ch vrol t Trucks, 1½ & 2 T n R ar Brak s (1954-60)

►*BRAKE BOOSTER NOTE:* Hydrovac Power Unit is Standard or Optional on all models.

DESCRIPTION: Two cylinder, four anchor type (each shoe anchored at each end and linked to wheel cylinder at each end). Brakes are radially self-centering.

ADJUSTMENT: Each shoe has one adjustment (adjusting screw at adjustable anchor end). Adjustment is same for both wear and for new or relined shoe clearance.

Brake P dal Adjustm nt: *See "Chevrolet-Bendix Hydraulic" for data.*

Brak Sho Adjustm nt: Jack up both rear wheels, remove adjusting hole covers from backing plates (two holes at each wheel—one for each shoe). Use tool J-4707 or screwdriver inserted through rear (lower shoe) adjusting hole and turn adjusting screw up (move outer end of tool toward center of wheel) until light brake drag is felt on wheel, then back off adjusting screw 3 notches for correct running clearance. Adjust upper shoe similarly by inserting tool through front adjusting hole.

Parking (Hand Brak) Adjustment: Parking brake is independent type mounted on propeller shaft at rear of transmission.

1½ & 2 T n—Fully release brake lever. Loosen locknut on outer shoe adjusting screw then tighten to secure a clearance of .010" to .015" measured at point directly above screw. Tighten locknut. Loosen locknut on link between hand brake lever and shoe actuating lever. Tighten adjusting nut on link to secure a clearance of .010" to .015" between inner shoe and drum. Tighten locknut.

BLEEDING BRAKE SYSTEM: Pressure or manual methods can be used.

Pr ssur Bl ding: 1) Back off adjusting screw all the way on upper shoes of both rear wheels. Fill master cylinder reservoir to top of filler plug opening. Connect pressure bleeder to master cylinder and open valve in bleeder tank line. (*NOTE*—Bleeder tank should be charged with 25-35 lbs. air pressure and kept at approximately this pressure during bleeding operation. End of bleeder tube must be in a bleeder jar or bottle and covered with fluid while performing all bleeding operations).

2) Connect bleeder tube to bleeder valves in following sequence, open bleeder valve and bleed until all air bubbles disappear, then close bleeder valve. Sequence as follows:

a) Hydrovac slave cylinder (No. 2 bleeder valve on end cap). *NOTE*—Will take approximately ½ pt. of fluid.
b) Hydrovac valve (No. 1 bleeder valve on top of control valve).
c) Front, rear wheel cylinder on left side.
d) Front, rear wheel cylinder on right side.
) Left front wheel cylinder (one only).
f) Right front wheel cylinder (one only).

3) Adjust upper shoe on each rear wheel with pressure tank still connected. Push down hard on brake pedal several times to centralize shoes. Disconnect pressure tank and readjust all brake shoes..

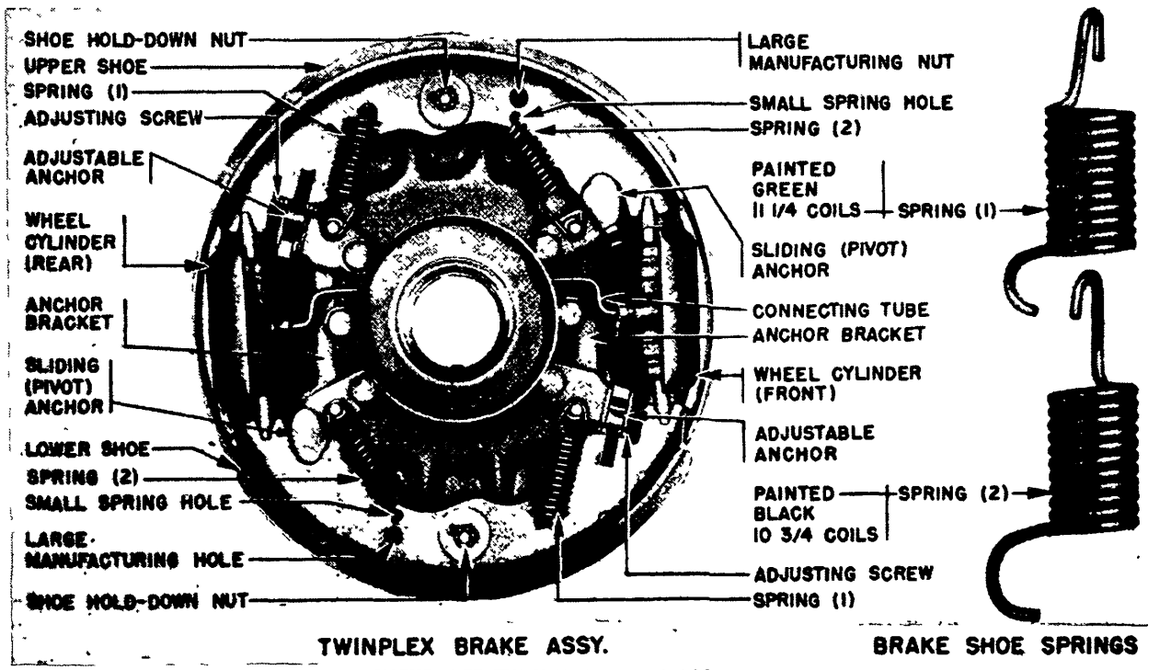
4) Apply approximately 75 lbs. pressure on brake pedal and check pedal clearance from toe board to forward edge of pedal pad. Clearance should be a minimum of 5" with floor mat removed. If reserve less than 5", rebleed Hydrovac and rear brakes in sequence outlined above.

Manual Bleeding: 1) Install adapter and automatic filler J-713. Connect bleeder tube to Hydrovac bleeder valve No. 2 (on end cap). Place end of tube in container having sufficient fluid to cover end of tube.

2) Open bleeder valve approximately ¾ of a turn, depress brake pedal a full stroke and allow it to return slowly, making sure end of tube is under surface of liquid in container. Continue operating pedal, refilling jar at master cylinder when necessary, until liquid emerging from bleeder tube is air bubble free. Close bleeder valve. Proceed to bleed system as outlined in steps **2) b)** through **f), 3) and 4)** under "Pressure Bleeding" above, using automatic filler in place of pressure tank.

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

BRAKE SHOE REPLACEMENT: Brake linings are riveted type and can be installed in the field after shoes have been removed.



Removal: Support rear end of truck on stands, remove rear wheels, back off adjusting screw for each shoe (two per wheel), remove brake drums by taking out 3 retaining screws on face of drum. Disconnect and remove all shoe pull back springs, remove hold-down nut on washer on web of each shoe. Disengage shoes from cylinder links, lift shoes out.

►*CAUTION: Stops on backing plate will prevent wh el cylinder pistons from coming out but brake pedal must not be depressed when drums are off.*

Installation: Lubricate shoe primary (sliding pivot) anchors and all shoe bearing surfaces on brake flange plate with light film of Lubriplate or Brake Lube. Install shoes, engaging ends of shoes with anchors and slotted ends of wheel cylinder links, and making certain that hold-down bolt enters hole in shoe web. Lubricate hold-down bolts and washers lightly with Lubriplate or Brake Lube, install washer and nut on each hold-down bolt and tighten nuts loosely. Install shoe pull back springs (*CAUTION*—see illustration and Note below for correct spring installation). Tighten each hold-down bolt nut until clearance between edge of shoe and contact face on flange plate is .010" (measure with feeler gauge). Install drums and adjust brakes.

►*BRAKE SHOE PULL BACK SPRING NOTE:* Different spring used at each end of shoes. Install springs thus: **Spring at Primary (Sliding Pivot) Anchor End of Sho** — 10¾ coil, 90 lb. type, painted BLACK for identification, with LARGE hook at shoe end of spring. Install spring with this large hook engaging small hole in shoe web.

CONTINUED ON NEXT PAGE

TWINPLEX BRAKE ASSY. BRAKE SHOE SPRINGS

CHEVR LET TWINPLEX BRAKE ASSY.

Form 49 B

CHEVROLET TWINPLEX (C nt.)

►*CAUTION: This spring must not be engaged in larger manufacturing hole in web adjacent to spring hole.* **Spring at Secondary (Adjustable) Anchor End of Shoe**—11¼ coil, 70 lb. type, painted GREEN for identification, with SMALL hook at shoe end of spring. Install this spring with this smaller hook engaging the large hole in the shoe web adjacent to the shoe adjusting wheel.

►*CAUTION: Interchanging springs or incorrect installation will result in uneven brake shoe wear and unsatisfactory brake operation.*

OVERHAUL: Brak Drums—Rebore brake drums if more than .010" out-of-round. Manufacturer recommends reboring to .060" oversize and use of .030" oversize lining (max. available oversize). Drum runout must not exceed .005".

Master Cylinder: *See "Hydraulic Brake Servicing".*

Wheel Cylinders: To remove wheel cylinders, first remove brake shoes, then take out capscrews holding wheel cylinder on backing plate and remove **both cylinders and connecting line as a unit.**

Disassembly—Disconnect line linking the two cylinders, remove rubber boots and shoe connecting links, withdraw pistons and rubber cups and springs from cylinder. *CAUTION—Do not remove rubber cups (piston rings) from grooves in pistons unless the cups be ing replaced.*

Inspection & Repair—Inspect cylinders for scores, scratches, and corrosion. Light scratches or lightly corroded areas may be cleaned up with crocus cloth, replace cylinder if these cannot be polished out. *(CAUTION*—Honing cylinders not recommended). Replace piston cups and cylinder boots if swollen or damaged. Piston clearance in cylinder .002-.004".

Reassembly—Dip all parts in brake fluid. Install piston and cup assemblies with cupped side toward spring or inward. *(CAUTION*—use care not to damage edges of cups). If new cups being installed, use tool J-4705 and install cups with open end toward flat end of piston.

FORD TRUCK BENDIX UNI-SERVO

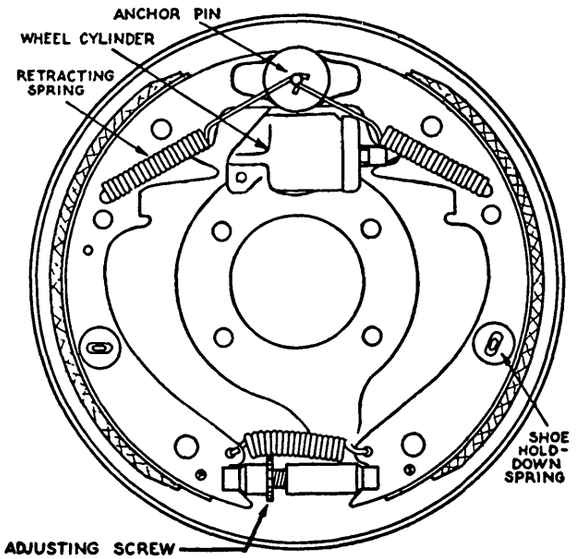
Ford Trucks - F-250; F, P-350; B, C, F, P-500; B, C, F-600 (1954-57). Front Wheels Only.
Ford Trucks - F-250; F, P-350; P-400; B, C, F, P-500; C-550; B, C, F-600 (1958-60). Front Wheels Only.

►*REAR BRAKE CAUTION: Different type brakes used on rear wheels as follows:*

F-2, 3; F-250; F, P-350—Ford-Bendix Hydraulic, Duo-Servo type. *See "Ford, Lincoln, Mercury Bendix".*

B, C, F, P-500; C-550; B, C, F-600 - Ford "Self-Centering" type. *See "Ford Truck Self-Centering".*

►*POWER BRAKE NOTE: "Hydrovac" or "Midland Hi-Power" Standard or Optional on these trucks. See "Hydrovac" or "Midland Hi-Power" under Power Brakes.*



►*1955 MASTER CYLINDER PUSHROD INSTALLATION CAUTION:* On F-100 Trucks master cylinder pushrod and clevis pin are installed in upper hole in brake pedal; on F-250, F-350 and F, B-500 pushrod and clevis pin are installed in upper hole with conventional brakes, and in lower hole with booster brakes; on B, C, F-600 pin and pushrod are installed in lower hole of brake pedal for both conventional and booster brakes.

DESCRIPTION: Bendix "Uni-Servo" single anchor, hydraulic type with single-acting wheel cylinder mounted on the backing plate and actuating the primary shoe through a strut (no direct connection to secondary shoe). Brake shoes are conventional Bendix type (joined by adjusting screw at lower end, single anchor between shoes at upper end with retracting springs hooked to each shoe and anchor pin). Wheel cylinder has single piston and cup with a return spring seated in the end of the cylinder.

ADJUSTMENTS: Make adjustments with brake drums at normal temperature and with wheels either jacked up or contacting road (if wheels on road so they cannot be checked for drag, make this check by striking drum with a hammer—sound will be deadened if shoes contacting drum).

Minor Adjustment: Remove adjustment hole cover from brake carrier plate. Rotate adjusting screw, with a suitable tool, until shoe begins to drag, then back off shoe 10-12 notches until drum can be turned without drag.

Major Adjustment: Rotate drum until feeler slot is at lower end of Secondary (rear) shoe, then insert a .010" thick feeler gauge between brake shoe and drum. Rotate drum and feeler gauge up along secondary shoe until feeler is wedged between secondary shoe and drum. Turn adjusting screw (star wheel) to expand shoes until a heavy drag is felt against drum, then back off adjusting screw just enough to give clearance of .010" between shoe and drum at a point 1½" from each end of secondary shoe. *NOTE - This clearance will give operating clearance for both primary and secondary shoes* When this clearance cannot be obtained, anchor pin must be adjusted.

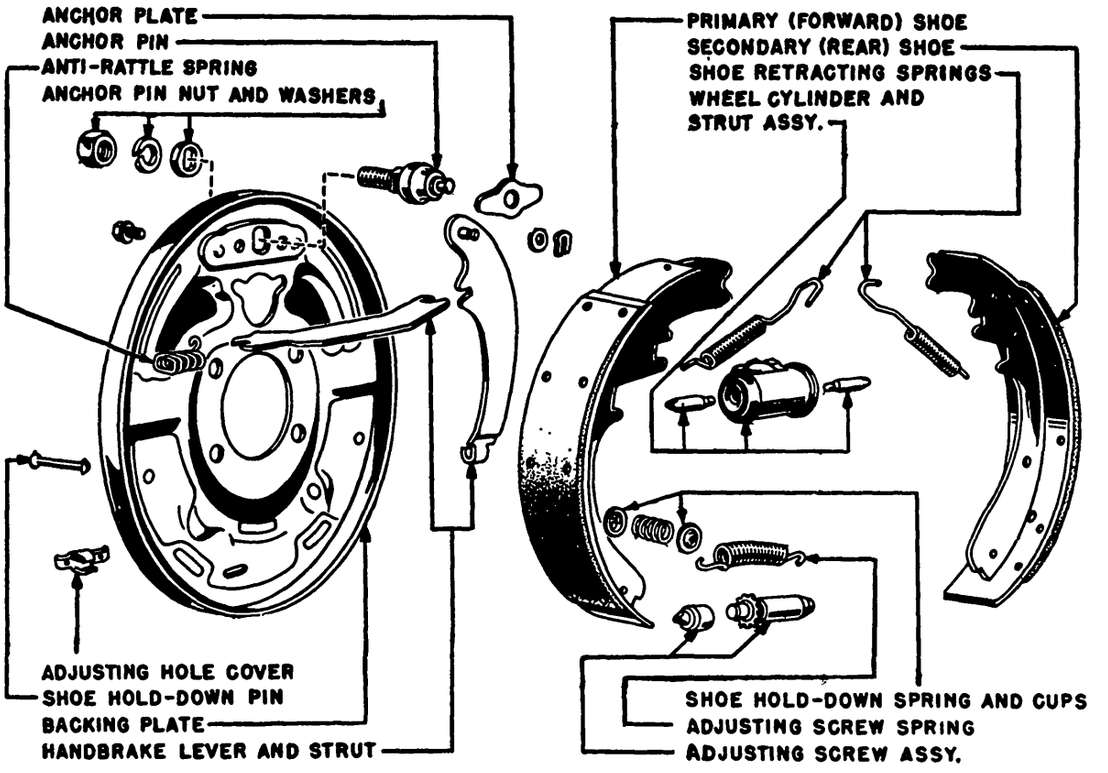
UNI-SERVO BRAKE ASSY.

Anchor Pin Adjustment - Loosen anchor pin nut just enough so anchor pin can be moved up or down (by tapping with soft hammer) centering shoes in drum and providing the 010" operating clearance at above positions Tighten anchor pin nut to 80-100 ft. lbs. Check other brake assembly.

Brake Pedal Adjustment: Brake pedal free travel should not be less than 3/16" nor more than 3/8" before push-rod touches master cylinder piston. Adjustable at master cylinder pushrod.

Parking Brake Adjustment: Set lever to first notch. Observe position of cam to make sure flat portion is resting on brake band bracket. If cam not flat with bracket, remove clevis pin from upper part of cam, then adjust clevis rod to allow flat portion of cam to rest on brake band bracket. Install clevis pin and cotter pin. Remove lock wire from anchor adjusting screw, turn adjusting screw clockwise until clearance of .010" is established between brake lining and brake drum at anchor bracket. Loosen locknut on adjusting screw for lower half of brake band, adjust screw to establish .010" between brake lining and drum at lower half of brake band. Tighten locknut. Turn upper band adjusting nut until .010" clearance established between upper half of band and drum. Be sure to install lock wire in anchor adjusting screw.

BLEEDING BRAKE SYSTEM: *See "Hydraulic Brake Servicing".*



BRAKE SHOE & DRUM REPLACEMENT: *See "Ford, Lincoln, Mercury Bendix".*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting".*

FORD MOTOR CO. BENDIX HYDRAULIC

FORD-BENDIX REAR BRAKE ASSEMBLY (WITH ADJUSTABLE ANCHOR PIN)

►CHANGES, CAUTIONS, CORRECTIONS

►*FORD TRUCK FRONT BRAKE CAUTION:* Ford-Bendix "Uni-Servo" used on front wheels of above listed trucks except F-1, 100.

►*1954 DESIGN & ADJUSTMENT CHANGE:* Front brakes of all 1954 Passenger cars have eccentric adjustment. Position of front brake assembly has been rotated to give access to anchor pin. A secondary shoe adjusting spring holds secondary shoe in released position. An eccentric, located behind secondary shoe, provides the stop. See Major & Minor Adjustments (With Eccentric) for adjustment procedures. Rear wheel brakes remain the same as previous models (without eccentric adjustment).

►*1955 FORD TRUCK MASTER CYLINDER PUSHROD INSTALLATION CAUTION:* On F-100 Trucks master cylinder pushrod and clevis pin are installed in upper hole in brake pedal for both conventional and booster type brakes; on others, master cylinder pushrod and clevis pin are installed in upper hole in brake pedal for trucks with conventional brakes and in lower hole for trucks with booster brakes.

►*1955 FORD PASS. CAR BRAKE LINING PRODUCTION CHANGE:* Effective approximately August 1, 1955, under-ground brake lining became effective in production. Adjustment procedures for both underground and uniform-ground linings are the same.

►*1954 FORD P-350 TRUCK HAND BRAKE CABLE INTERFERENCE CORRECTION:* To prevent interference between hand brake cable and clutch pedal, attach one clip, Part No. 91A-2279, to upper bolt in seam of left front wheel splash shield, and another clip, Part No. 352605-S8, to boss at top left rear corner of cylinder block. Cable should pass from hand brake lever to 91A-2279 clip, then up to 352605-S8 clip on engine. Be sure cable is positioned between steering column and sheet metal.

►*BRAKE SHOE RETRACTING SPRING PRODUCTION CHANGE & REPLACEMENT CAUTION (Pass. Cars):* Effective production Aug. 24, 1955 a new oil tempered brake retracting spring, Part No. B5A-2035-A, has been used to improve brake life and performance, and should be installed on units produced prior to above date. When installing spring, avoid bending end hooks or stretching beyond attaching point.

►*1955 FORD PASS. CAR PRIMARY BRAKE LINING & SHOE PRODUCTION CHANGE:* A new primary brake lining and modified brake shoe has been released for front and rear wheels. New lining is shorter in length, and is intended to reduce "pulling or diving" on brake application. **New linings may be installed on earlier type shoes,** and earlier type linings may be used on the new type shoes. In either case, two new holes must be drilled in the shoes using the holes in the lining as a template. *NOTE*—Shortened end of primary linings must be located at anchor (upper) end of shoe. When installing new linings on earlier type shoes, two holes must be drilled at anchor end. When relining brakes, make sure new type (shorter) and old type linings are not mixed.

Car Model	Lining Kits Front Wheel Kit	Rear Wheel Kit
Car	B5A-2007-G	B5A-2007-H
Car (Hvy. Duty)	B5A-2007-L	B5A-2007-M

Thunderbird	B5S-2007-B①	

①—Lining kit for both front and rear wheels.

►*1955 FORD PASSENGER CAR ADJUSTMENT CHANGE:* Eccentric is located on primary shoe. Initial adjustments made on primary instead of secondary shoe. Adjusting spring is no longer used.

►*1955 FORD PASS. CAR BRAKE LINE INTERFERENCE WITH OIL FILTER CORRECTION:* Clip, Part No. B4A-2244-A, and attaching screw, Part No. 39883-S7, now available to secure brake line to rear side of No. 2 crossmember. On vehicles not equipped with additional clip (now used in production), and on which interference is encountered, proceed with installation of additional clip as follows Locate and mark spot on No. 2 crossmember 4½" to left, and 4 15/16" up from center of existing clip at left hand rear side of crossmember. Drill 9/32" hole at this spot. Position brake line on crossmember, and secure line with clip and screw. *NOTE*—Brake line will move far enough to permit installation without bending or crimping line.

►*1955 LINCOLN & MERCURY FRONT BRAKE PRODUCTION CHANGE:* Front brake eccentric adjuster has been eliminated on later cars and no eccentric adjustment is required. See Adjustments below

►*1955 LINCOLN & MERCURY BRAKE ADJUSTMENT CHANGE:* Adjustment procedures are affected in that eccentric cam is now spring loaded, which eliminates need for lockout to retain it in position. See Adjustments below and also Production Change above.

►*1956 LINCOLN & CONTINENTAL BRAKE SQUEAL CORRECTION:* An anti-squeal spring, Part No. 51A-1140, is available for installation on outside of brake drum. Spring should be installed on a clean drum only.

►*BINDING BRAKE PEDAL CORRECTION:* Brake pedal spacer, Part No. LD-22483-A, is manufactured with large chamfers on the ends. If brake pedal shaft nut is over-tightened, ends of spacer tend to score side walls

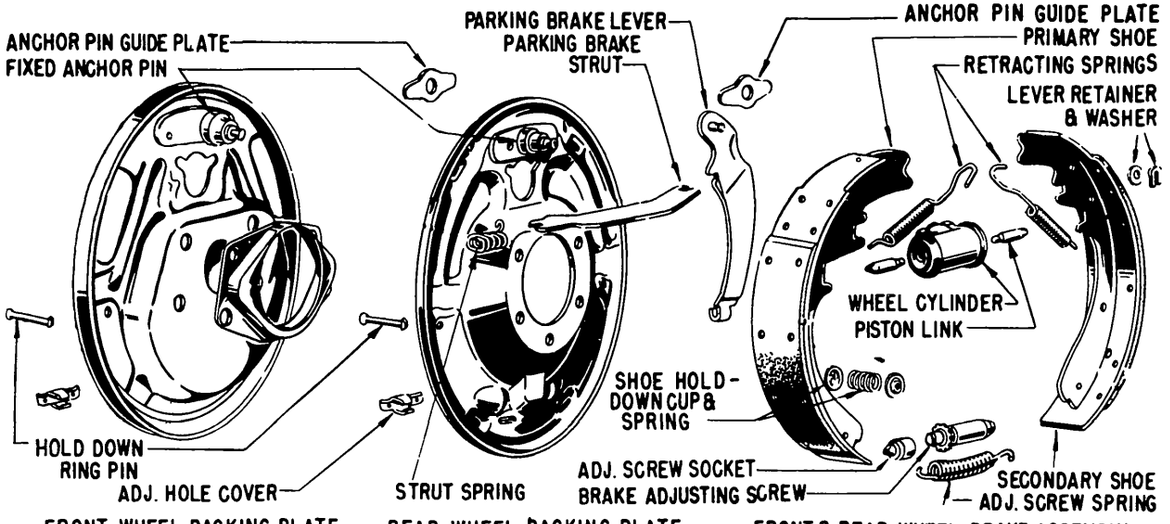
C NTINUED N NEXT PAGE

FORD MOTOR CO.
BENDIX (C n't.)

of the support, reducing side wall spacing and causing interference with brake pedal hub. Paint in this area can also be a contributing factor to interference. Replace worn or damaged parts. Reduce length of hub to provide fit but do not remove more than .020" or a rattle may develop.

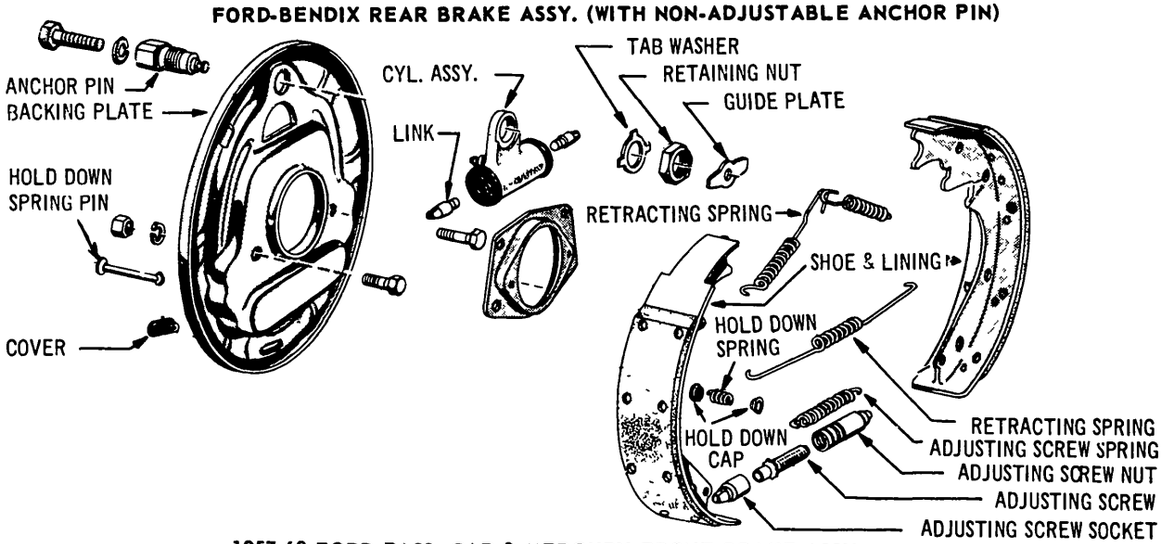
►*1954-56 MERCURY BRAKE SHOE RETRACTING SPRING PRODUCTION CHANGE:* New oil-tempered spring (painted brown) Part No. B5A-2035-A released to improve spring action.

►*1955 FORD & THUNDERBIRD BRAKE LINING CHANGE & REPLACEMENT CAUTION:* Later cars have "shorter" Primary Shoe Brake Lining and modified brake shoes to reduce any tendency toward pulling or diving when brakes applied. This new primary lining should be installed only as sets and must not be mixed with previous longer lining. If new lining installed on old shoes, shorter end of lining must be toward anchor end of shoe and it will be necessary to drill two additional holes for rivets at anchor end of lining (use new lining as template in drilling holes). *NOTE* - Previous type lining can also be used on new shoes but also requires drilling of two holes. *Install first type (longer) or later type (shorter) Primary Linings only in sets and DO NOT mix linings.*



►*1957 FORD ANCHOR PIN BOLT TORQUE:* Torque specifications for front brake anchor pin attaching bolt is 80-100 ft. lbs. When checking sources of trouble for a brake pulling condition, it is recommended that anchor pin bolt be backed off and retightened to 80-100 ft. lbs.

►*1957 MERCURY BRAKE HOSE RUBBING CORRECTION (EARLY CARS):* Rear brake hose may rub on left rear shock absorber. To correct, install new rear axle brake tube fitting Part No. MG-2074-B. *NOTE - Station wagons use Part No. MG-2074-A only.* If old fitting used, twist hose by removing from brake tube and twisting counterclockwise 1 hex flat.



►*1957 MERCURY REAR BRAKE HOSE TENSION CORRECTION (EARLY CARS):* Rear brake hose on some early cars may be under tension. Correct by bending frame bracket tab approximately ¼" to rear *(CAUTION - Do not damage connection between hose and brake tube),* or install ¾" longer hose, Part No. ED-MA-2078-A.

►*1957 MERCURY SPONGY PARKING BRAKE CABLE CORRECTION (EARLY CARS):* If cable has spongy feel, install dash panel retaining clip, Part No. 361767-S8-UP. Drill 13/64" hole in upper portion of "Y" dash panel reinforcement. Install clip with ¼" x 20 self-tapping screw no longer than ½". *CAUTION* - Cable must be free of binding and kinking and not interfere with speedometer cable.

►*1957 MERCURY PARKING BRAKE SPECIFICATION CHANGE:* Two equalizer lever retracting springs installed on later cars to assure positive release of parking brake. When releasing difficulties occur install the second spring, Part No. MG-22794-A. *NOTE - It is important that brake for installing a second retracting spring, the parking brake mechanism be checked and any binding condition and/or improper adjustments be corrected.*

FORD-BENDIX REAR BRAKE ASSY. (WITH NON-ADJUSTABLE ANCHOR PIN)

1957-60 FORD PASS. CAR & MERCURY FRONT BRAKE ASSY.

►*1958 FORD PASS. CAR BRAKE LINE INTERFERENCE WITH FUEL LINE CORRECTION:* On cars except Station Wagons and Retractable Hardtops, brake line may interfere with fuel tank line during rear axle jounce. To correct, position brake line flush against rear axle and make sure there is ½" minimum clearance between fuel line and floor pan.

►*1958 LINCOLN PARKING BRAKE PEDAL NO RETURN CORRECTION:* May be caused by insufficient tension of retracting spring at equalizer. Tension should be 18 lbs. Reform hooks on spring ends to correct.

►*1960 FORD PASS. CAR & THUNDERBIRD LEFT REAR WHEEL ADJUSTING SLOT NOTE:* This slot will be located rearward of vertical centerline (instead of forward of centerline) which changes position of adjusting screw and also reverses the brake adjusting screw rotation (left rear wheel only).

►*1960 COMET REAR WHEEL BRAKE CYLINDER CRACKING NOTE:* Over tightening rear wheel brake tube nut to rear wheel cylinder may result in damage to tube seat surface and possible cracking of the boss in rear wheel cylinder. It is recommended that a "crowfoot" adaptor be used with a torque wrench to tighten tube nut. With the adaptor, tighten nut to 10-11½ ft. lbs.

CONTINUED ON NEXT PAGE

FORD MOTOR CO.
BENDIX (C nt.)

DESCRIPTION

DESCRIPTION: Duo-Servo, single anchor, hydraulic type. *NOTE* - Eccentric used on front wheels of all 1954 Models, 1955 Pass. Car Models and Early 1955 Lincoln and Mercury Models. All 1956 and later Models (Exc. Ford Trucks and Thunderbird), do not use eccentric and the anchor pins are fixed so no major adjustment is required. On Ford (1957-60 Exc. 1957 Thunderbird), Mercury (1957-58), the front wheel anchor pin is mounted on wheel spindle through wheel cylinder and backing plate.

Parking Brak P dal (1958 Lincoln, 1957-58 Mercury) - Toe-set parking brake pedal used instead of T-handle. Located to left of regular foot brake pedal. Set by pushing forward on pedal. On Mercury, release by pushing bar on left end of instrument panel (Auto. Trans. - mounted on selector keyboard).

ADJUSTMENTS

ADJUSTMENTS: Before making any adjustments, jack up all four wheels, check brake pedal clearance (see below), fully release hand brake lever and make certain that all wheels turn freely (Parking brake cables should be disconnected when vehicle is raised on frame hoist). Anchor pin bolt should be tightened to 80-100 ft. lbs. Drums should be at normal room temperature.

BRAKE PEDAL ADJUSTMENT

Brake Pedal Adjustm nt: Adjust as follows:

Comet, Falc n, Ford Pass. Cars (Exc. 1960), Lincoln Thunderbird - 5/16-7/16"; Mercury 1/4-7/16"; Ford Trucks 3/16-3/8" pedal freeplay. *NOTE - 1960 Ford Pass. Cars have non-adjustable pushrod.*

Ford Trucks (1954-56) - Loosen locknut on master cylinder pushrod, remove clevis pin on brake pedal, turn pushrod in or out as necessary, tighten locknut.

Ford Trucks (1957-60) & All Other Models - Loosen master cylinder pushrod to brake pedal eccentric bolt locknut and rotate bolt until free play is within specications.

MINOR ADJUSTMENT

Min r Adjustment (1954-55): Lincoln & Mercury - Use feeler gauge to set shoe clearance to .010". See *Major adjustment for data.*

Minor Adjustment (1954-55 Ford Pass. Car Front Wheels): Check anchor pin with 16" wrench (if loose, Major Adjustment is necessary). Expand brake shoes by turning adjusting screw (star wheel) toward center of brake until it is just possible to rotate drum. Back off adjusting screw 10 to 14 notches. While slowly rotating drum, turn eccentric cam in direction of forward rotation until slight drag is felt, then back off eccentric cam to have a freely rotating drum. *NOTE*—Tap backing plate with hammer when backing off eccentric cam to center shoes. If drum does not rotate freely after backing off adjusting screw and carefully setting eccentric cam, a Major Adjustment is required.

Minor Adjustment (1954-55 Ford Pass. Rear Wheels): Disconnect parking brake cable at equalizer clevis pin. Turn adjusting screw (toward axle) until wheel can just be turned by hand. Back off adjusting screw 10 to 14 notches (away from axle). Wheel should rotate freely. If drag felt, Major Adjustment is required. Connect parking brake cable and adjust. Apply brakes and measure distance from pedal pad to floor board. If distance less than ½ of total travel, Major Adjustment is required. *NOTE*—If car has booster brakes, check must be made with engine running.

Minor Adjustment (Lincoln & Mercury Front Wheels): Two adjustments required as follows:

Eccentric Cam Adjustment—Raise car and remove front wheels. Insert .010" feeler gauge through drum slot and check clearance at lower end of secondary shoe. Feeler gauge should be just snug. To adjust clearance, rotate cam adjusting stud in direction of forward wheel rotation to decrease clearance. To increase clearance, rotate cam in opposite direction. Check clearance at upper end of secondary shoe (.010"). The clearance at both ends should be same within .003". Where variation is greater, make Major Adjustment.

Adjusting Screw Adjustment—Remove adjusting hole cover and insert .010" feeler between lining and drum near lower end of primary shoe. Hold primary shoe snug against feeler. To decrease secondary shoe clearance, rotate adjusting screw from top to bottom, and to increase secondary shoe clearance rotate adjusting screw from bottom to top. Then recheck clearance at both ends of primary and secondary shoes. Check that all brake drums are free of lining drag.

Minor Adjustment (1956-60 Exc. Thunderbird; 1957-58 Mercury; 1958 Lincoln): Remove adjusting hole cover and rotate adjusting screw until shoe begins to drag (Ford Pass. Cars & Trucks), or tight against drum (Lincoln & Mercury). Then back off adjusting screw 10-12 notches (Ford Pass. Cars & Trucks), 12-14 clicks (Lincoln & Mercury) until no drag is felt.

Minor (Wear) Adjustment (Thunderbird): Raise car, make sure brakes are fully released. Loosen eccentric bolt locknut. Remove adjusting hole cover and turn adjusting screw until shoes drag on drum. Then back off screw 14 to 16 notches. Turn eccentric bolt in direction of forward wheel rotation until secondary shoe drags on drum. Back off eccentric bolt until no drag is felt. Tighten locknut.

MAJOR ADJUSTMENT

Major Adjustment (Except 1954-55 Ford Pass: Cars): ►*CAUTION: Recommended procedure for Ford is not the same as for Lincoln & Mercury.*

Ford—Wedge the primary shoe out against the drum by inserting a .010" feeler gauge through the slot in the drum at the center of secondary shoe and expand shoes by turning adjusting screw. Then adjust adjusting screw and anchor pin (slotted type) for .010" clearance at each end of secondary shoe (measure 1½" from each end of shoe).

Lincoln & Mercury—The shoe clearance should be .010" at all points. Check by inserting .010" feeler through slot in brake drum and measuring clearance at several points. Adjust by turning adjusting screw (accessible through slot in backing plate) and by shifting anchor pin if necessary (pin hole is slotted and will allow an up-and-down shifting of anchor pin to correctly center shoes). Torque anchor pin nuts to 80-120 ft. lbs.

Major Adjustment (1954-55 Ford Pass. Car Rear Wheels): Adjust in manner similar to front brakes, omitting eccentric cam adjustment. Connect parking brake cable and adjust.

Major Adjustment (Lincoln & Mercury Front Wheels): *NOTE:* Major adjustment performed only if Minor Adjustment unsatisfactory, or that upper end of anchor has less clearance than lower end.

Anchor Pin-Eccentric Adjustment—Complete operations of rotating Cam Adjusting Stud for secondary shoe clearance as shown in Minor Adjustment. Then adjust anchor pin and eccentric to obtain .010" clearance at each end of secondary shoe. To adjust anchor pin end, loosen anchor pin nut one full turn, tap pin lightly upward, with soft hammer, to decrease clearance or downward to increase clearance. Recheck lower clearance to insure that anchor pin adjustment did not alter lower end of secondary shoe clearance. If lower secondary shoe clearance not correct insert .010" feeler between lining and drum of primary shoe at lower end of shoe and with shoe snug against feeler turn adjusting screw from top to bottom to decrease secondary shoe clearance and from bottom to top to increase clearance. Recheck all clearances and repeat anchor pin adjustment if necessary to maintain a greater clearance at anchor pin end not to exceed .003". Recheck all clearances, replace wheels and road test. Torque anchor pin nuts to 80-120 ft. lbs.

Major Adjustment (1954 Ford Pass. Car Front Wheels): Expand brake shoe by turning adjusting screw (star wheel) toward center of brake until it is just possible to rotate drum. Back off screw 10 to 14 notches. Position drum so inspection slot is within 1" of upper end of secondary rear lining. Insert a .010" feeler between lining and drum at this point. Loosen anchor pin nut one turn and tap with a soft hammer to establish a .010" clearance. Do not tighten anchor pin locknut at this time. Insert .010" feeler 1" from adjusting screw end of secondary lining. Adjust eccentric to obtain .010" clearance. Recheck clearance at anchor end of secondary lining. After clearance has equalized at .010" at both ends of lining, tighten anchor pin locknut to 65-85 ft. lbs. Recheck clearance on secondary shoe to make sure anchor pin has not moved. Check clearance at center of primary lining with .010" feeler. Turn adjusting screw (star wheel) to obtain a .010" clearance on primary lining.

Major Adjustment (1955 Ford Pass. Car Front Wheels): Turn adjusting screw toward center of brake until shoes are tight in drum. Push adjusting screw star wheel toward primary shoe lining. Position drum so inspection hole is within 1" of upper end of secondary (rear) shoe lining. Insert a .010" feeler between lining and drum at this point. Push secondary shoe against feeler by pushing on adjusting screw star wheel. Remove feeler, rotate drum until slot is 1" above lower end of secondary shoe. Do not force shoe out of position. Check clearance at this point with feeler gauge. If greater or less than .010", loosen anchor nut approximately 1 turn. Tap anchor pin in direction of greater clearance (up or down) with soft hammer. After clearance of secondary shoes have been equalized at .010" at both ends, tighten anchor pin nut to 65-85 ft. lbs. Recheck clearance on secondary shoe to be sure

CONTINUED ON NEXT PAGE

FORD MOTOR CO.
BENDIX (C nt.)

anchor pin did not shift. Rotate drum so slot is over any part of primary shoe lining. Insert a .010" feeler between drum and lining. With feeler in place, move drum back and forth keeping inspection slot and feeler over primary shoe lining, at same time rotating eccentric cam in same direction as forward wheel rotation, until a .010" clearance is established between closest point of lining and drum. This should provide clearance for both shoes. If any drag noted, adjusting screw may be backed off another 1 or 2 notches.

Major Adjustment (Ford Trucks with Adjustable Anchor Pin): Rotate drum until feeler slot is at lower end of Secondary (rear) shoe, then insert .010" feeler between brake shoe and drum, and rotate drum, moving feeler gauge up along secondary shoe until shoe assembly is wedged forward as much as possible. Turn adjusting screw until primary shoe contacts drum securely and secondary shoe is snug against feeler. Back off, adjusting screw to obtain .010" clearance 1½" from each end of secondary shoe. If .010" clearance cannot be obtained at both ends of secondary shoe, an anchor pin adjustment is needed.

Anchor Pin Adjustment - Loosen anchor pin nut just enough to permit moving pin up or down by tapping nut with soft hammer. *NOTE - DO NOT BACK NUT OFF TOO FAR AS SHOES WILL MOVE OUT OF POSITION WHEN NUT IS TIGHTENED.* Move anchor pin up or away from center of drum to reduce clearance at anchor end of secondary shoe, and down to increase clearance. Tighten anchor pin nut securely and recheck secondary shoe clearance.

HAND BRAKE ADJUSTMENT

Hand Brake Adjustment: All Pass. Cars and F-1, 100 Trucks (Exc. 1957-58 Mercury and 1958 Lincoln) (1954-60); F-250 and P-350 Trucks (1957-60). Adjust service brakes. With service brakes fully released, place parking brake lever in fully applied position. Equalizer should not touch frame crossmember. Adjust cable from control handle to equalizer lever as necessary. There should be no slack in parking brake cables with control lever in fully released position. To adjust, loosen locknut on equalizer rod, tighten adjusting nut to remove slack. Pull cables alternately to equalize tension on each through yoke, tighten locknut. *CAUTION* - Overtightening cables will pull rear brake shoes off their anchors.

Mercury Parking Brake Release Rod Adjustment (1957): Disconnect parking brake release rod trunnion from release arm of pedal assembly. Turn trunnion on rod until it freely enters hole in pedal release arm with arm in locked position. Turn trunnion 1 turn to shorten rod.

Mercury Parking Brake Adjustment (1957): Depress parking brake pedal 1". Make adjustment as in Ford above. Distance from end of equalizer bracket to center of equalizer rod hole should be 2 1/16" ± 1/16". Parking brakes should be fully applied when pedal is depressed 2".

Lincoln Parking Brake Adjustment (1958): Depress pedal 1" and adjust equalizer until a slight drag on rear drums is felt. Release pedal and make sure brakes are released and that there is no drag.

Mercury Parking Brake Adjustment (1958): With parking brake fully released and rear wheels free to turn, loosen parking brake cable at equalizer lever. Depress pedal 1" and adjust front and rear cables until slight drag is felt on rear drums. *NOTE - Adjustments should be equally divided between both cables. Distance from end of equalizer bracket to center of equalizer rod hole with pedal depressed 1" should be ¼".* Tighten equalizer locknut. Release parking brake and make sure rear shoes return to released position. Car should be held with brake pedal depressed 2".

F-2, F-3, F-250, 350; P-350 Trucks (1954-56); P-400, All 500 & 600 Series Trucks (1957-60) - These models have independent brake on propeller shaft at rear of transmission. *See "Ford Truck Bendix Uni-Servo" for data.*

OVERHAUL

BLEEDING BRAKE SYSTEM: ***See complete "Hydraulic Brake Servicing" for bleeding instructions.***

►*1958 LINCOLN BLEED SCREW CAUTION:* A bleed screw is provided in master cylinder to aid in bleeding operations. DO NOT tighten screw more than 80 INCH LBS. or aluminum housing of master cylinder may crack.

TROUBLE SHOOTING: ***See "Hydraulic Brake Trouble Shooting" for complete data.***

BRAKE DRUM REPLACEMENT: Brake drums are "demountable" type (removable without disturbing wheel hub) on all models except Ford Pass. Car & Station Wagon **front wheels.** To remove brake drums take off nuts or remove capscrews or bolts holding drum on wheel hub or axle shaft flange. **Drum Regrinding Note**—When refinishing drums, inside diameter must not be increased more than .060" (not more than .030" removed from drum wall).

BRAKE SHOE REPLACEMENT: With wheels and brake drums removed, brake shoes are removed and replaced as follows:

Removal: Disconnect brake shoe return springs at anchor pin, remove hold-down cup, spring, and pin on each shoe. Disconnect hand brake cable at lever on rear wheel brake rear shoe. Pull shoes out at top to free wheel cylinder piston links, lift shoe assembly out, lift out hand brake strut and anti-rattle spring on rear wheel brakes. Disassemble shoes by removing adjusting screw spring (free spring by moving anchor pin end of shoes together) and lifting off adjusting screw assembly.

Relining Brake Shoes: Lining should be replaced when worn to point where rivet head less than 1/32" below surface of lining. Inspect shoes for distortion or looseness between rim and web. Clean shoe rim and remove all burrs or high spots before installing new lining. After riveting, new lining must be snug against shoe with not more than .005" separation midway between rivets.

►*BRAKE LINING NOTE*—Lining furnished in brake lining kits is ground in production and does not require grinding after installation.

Installation: Lubricate all points of contact between brake shoes and other brake parts with Lubriplate. Assemble both brake shoes with adjusting screw and spring (see illustration). On rear wheel brakes, assemble parking brake lever on rear (secondary) shoe and install link. Install shoe assembly on backing plate, install hold-down cups and springs, install return spring. Install drums and adjust brakes.

OVERHAUL: Master Cylinder & Wheel Cylinders. ***See "Hydraulic Brake Servicing" for complete data.***

►***BRAKE OVERHAUL NOTE:*** *When overhauling front wheel brake assemblies with eccentric cam adjustment, it is necessary to remove eccentric spring before removing shoe. Replace spring after shoe installed.*

FORD TRUCK SELF-CENTERING

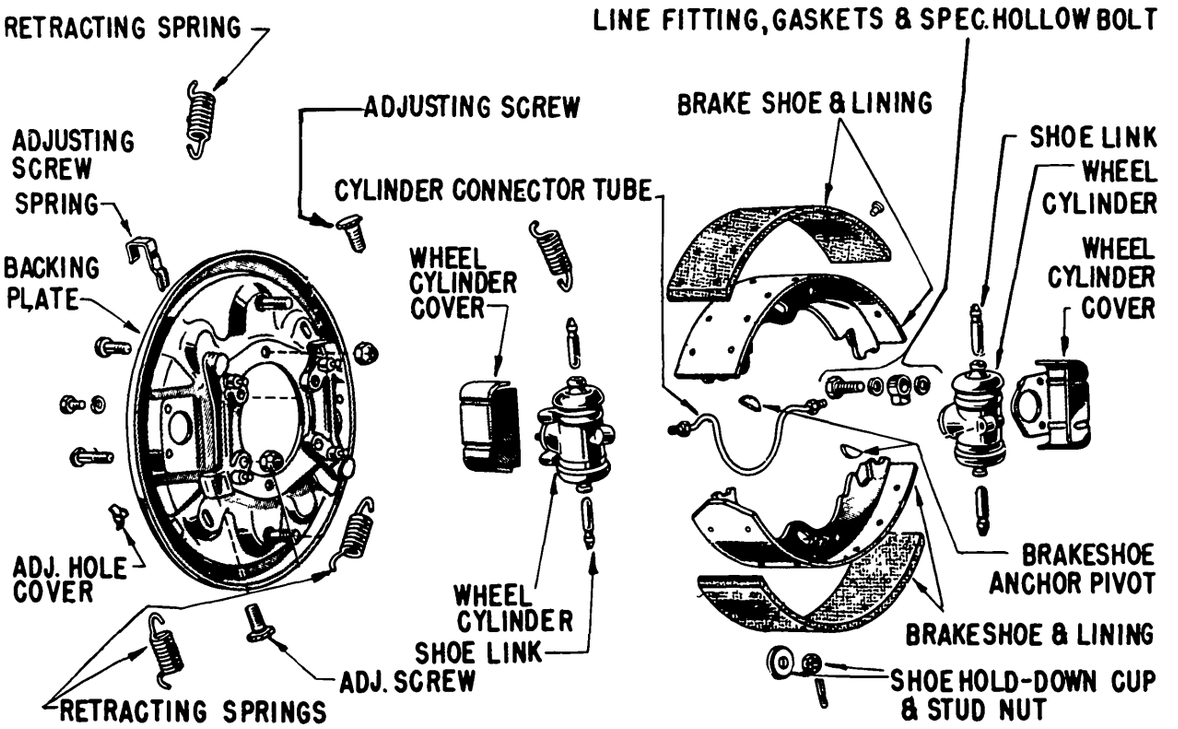
Ford Trucks - Series 500, 550, 600 (1954-60). Rear Wheels Only.

►CHANGES, CAUTIONS, CORRECTIONS

►*FRONT WHEEL BRAKE CAUTION: Ford-Bendix "Uni-Servo" type brakes used on front wheels of these models.*

►*POWER BRAKE NOTE: "Hydrovac" or "Midland Hi-Power" Standard or Optional on these trucks. See "Hydrovac" or "Midland Hi-Power" under Power Brakes*

►*1959 BRAKE PRODUCTION CHANGE & ADJUSTMENT CAUTION:* On later type brakes, the wheel cylinder were changed from a 60° off vertical position to a vertical position. When installing new lining on later type brakes, it will be necessary to adjust brake hold down bolt until a clearance of .045" is obtained between brake shoe gauge surface and brake backing plate. On earlier brakes, the clearance remains at the original .025" clearance.



►*BRAKE SHOE RETRACTING SPRING REPLACEMENT NOTE:* If retracting springs are stretched to the point where the free length exceeds 3", measured between inner side of hook on elongated end of spring and inner side of opposite end coil, or if a .010" feeler gauge can be inserted between two or more spring coils, replace the spring.

DESCRIPTION: Two-cylinder, two-shoe, four-anchor type hydraulic brakes. Each shoe is anchored at each end and linked to wheel cylinder at each end so that all shoes are self energizing for both forward and reverse motion. All shoes are radially self-centering.

ADJUSTMENT: Make adjustments with brake drums at normal temperature and with wheels either jacked up or contacting road (if wheels on road so they cannot be turned to check for drag, make this check by striking drum with a hammer - sound will be deadened if shoes contacting drum). Remove two adjusting hole covers on backing plate (adjacent to right hand anchor bolt at each wheel cylinder), insert tool through slot and turn notched adjusting screw "star wheel" until linings drag on drum, then back off adjusting screw until wheel is free of drag. Depress pedal to centralize shoes and recheck wheels. Adjust each shoe in each wheel in this manner. *NOTE* - When brake linings are replaced, an additional adjustment is required. Adjust shoe hold-down bolt until a clearance of .025" (1954-59), .045" (1960), is obtained (measure from brake shoe to gauge surface on backing plate). Gauge surface is machined boss on brake plate which is in line with hold down bolt.

Brake Pedal Adjustment: Pedal must have at least 3/16" but not more than 3/8", free travel measured at pedal pad before master cylinder piston begins to move. To adjust, loosen locknut on brake pedal to master cylinder pushrod, rotate rod until free travel within limits, tighten locknut to 25-30 ft. lbs. torque.

Parking Brake Adjustment: On cable controlled parking brakes, move parking brake lever to fully released position. On transmission mounted parking brake levers set lever to first notch. Observe position of cam to make sure flat portion is resting on brake band bracket. If cam not flat with bracket, remove clevis pin from upper part of cam, then adjust clevis rod to allow flat portion of cam to rest on brake band bracket. Install clevis pin and cotter pin. Remove lock wire from anchor adjusting screw, turn adjusting screw clockwise until clearance of .010" is established between brake lining and brake drum at anchor bracket. Loosen lock nut on adjusting screw for lower half of brake band, adjust screw to establish .010" between brake lining and drum at lower half of brake band. Tighten locknut. Turn upper band adjusting nut until .010" clearance established between upper half of band and drum. Be sure to install lock wire in anchor adjusting screw.

FORD TRUCK SELF-CENTERING BRAKE ASSEMBLY

DISASSEMBLY: *NOTE* - Brakes can be serviced without removing hubs or disturbing wheel bearings. Remove wheels, then screws holding drum to hub (mark drum and hub to insure correct assembly). *(CAUTION - If wheel cylinder connecting tubes and bleeder screws removed, mark ports to which tubes attached to assure correct reassembly).* Disassemble brakes as follows: Remove retracting springs. *CAUTION - On 500 or 600 Series note location of each of four retracting springs before removal (2 each of 2 different springs used).* Remove shoe guide bolt nut, washer and bolt, remove shoes.

REASSEMBLY: *(NOTE* - For best results, new shoe and lining assemblies should have the lining of correct thickness ground to proper radius concentric with brake drum. If linings are not ground, it may be necessary to readjust the linings after the linings have been "worn in". Make sure no nicks or burrs are on shoe edge at point of contact with brake plate). Place light film of Lubriplate on primary (sliding pivot) anchor and shoe bearing surfaces on brake plate. Position brake shoes in anchors and in slotted ends of wheel cylinder. Apply light film of Lubriplate to hold-down screw, then install hold-down screw, washer and nut. Tighten hold-down nut until there is a clearance of .025" (1954-59), .045" (1960) between center of machined bosses (three lugs) on plate and edge of shoe. This clearance is necessary to hold shoe parallel to drum and prevent shoe from binding against outer machined bosses. Install retracting springs, wheel cylinder brake pipe, drum assembly and wheel, then adjust brakes.

BLEEDING BRAKE SYSTEM: Bleed **top** wheel cylinder **first,** then lower. If power unit used, unit must be bled before wheel cylinders, with engine off and no vacuum in power unit system. *See "Hydraulic Brake Servicing" in Brake Section of Manual.*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" in Brake Section of Manual.*

AUBURN

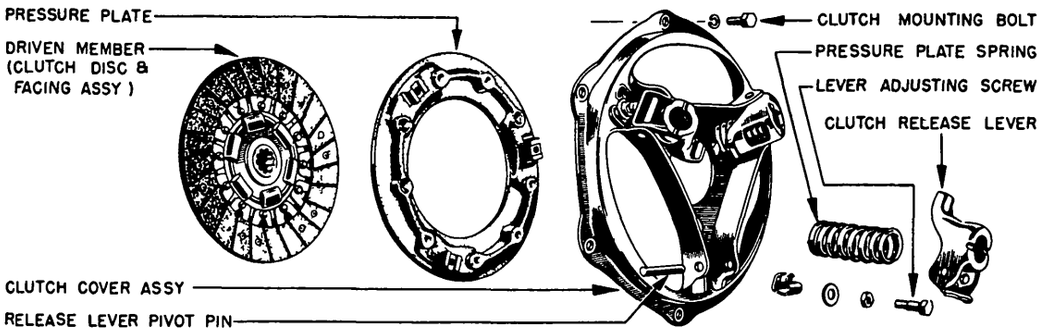
Dodge & Dart 6 Cyl. (1954-60) ①
Plym uth 6 Cyl. Exc. Ov rdrive (1954-60) ①
Willys (Exc. 6-226) (1954-57) ①②
Willys 6-226 (1955) ①
Willys, All M dels (1958-60) ①③
① - Borg & Beck Clutch also used
② - Rockford Clutch also used
③ - Two types used (heavier springs used on 6 Cyl. 2-Wheel Drive Models)

►CHANGES & CORRECTIONS

►*1958 WILLYS CLUTCH PRODUCTION CHANGE NOTE:* Improved Clutch Pressure Plate, Willys No. 917257 used on Models 6-226 4x4 & 4WD beginning Engine No TW-6-L-T-75827, and on FC-170 beginning Engine No. TW-6-L-F-13801

►*1958 WILLYS 4-CYLINDER CLUTCH VIBRATION CORRECTION:* Install improved clutch driven plate, Willys No 918870, which replaces No. 804327 New clutch driven plate identified by two helper springs located inside two opposed standard vibration springs

AUBURN-ATWOOD NOTE: Clutches made by Auburn Company and formerly listed as "Atwood" now called "Auburn" clutches.



►**RELEASE LEVER INTERFERENCE (causing premature clutch w ar on first CJ-3A Jeeps):** On these cars and other models, check for interference between edges of clutch release lever and lever opening in bell housing which prevent full clutch engagement and cause premature wear of the clutch facings. If interference noted, enlarge opening in bell housing by using a 1/8" or 3/16" drill to drill line of holes vertically 3" forward of rear edge of original opening, and horizontally 3/16" above top edge, and 1/8" below lower edge of original opening, joining the vertical line of holes with the original opening. Break out section of metal within this area with a wrench or drift.

WILLYS DRIVEN MEMBER NOTE: Borg & Beck driven members used on all models. *See Borg & Beck Type "A" Clutch s.*

DESCRIPTION: Clutch is single plate, dry disc type. Cover consists of a three-legged spider with channel section legs in which the clutch springs and release levers are mounted. Release levers pivot on pins riveted in cover legs and actuate pressure plate through adjustable screws in pressure plate under outer end of each lever. Springs are mounted in cups on cover under each lever Hairpin type retracting springs are mounted on each adjusting screw and are retained by the adjusting screw locknut

Willys Pr ssure Plat Assembly (8501-19 Clutch). Has neoprene rubber inserts at sides of pressure plate plate driving lugs (to prevent rattling or fizzing noise when disengaged) and flat Return Clip Spring on each release lever (to insure full disengagement)

REMOVAL OF CLUTCH: *See "Clutch" on car pag .*

AUBURN CLUTCH

►*OVERHAUL TOOL NOTE Use Tool C-585A (Dodge & Plymouth), Tool C-585-C (Willys)*

OVERHAUL: Disassembly (Using Special Tool) - Place cover support plate over main screw of fixture Install clutch cover assembly on the tool Mark the cover and pressure plate with punch and install compression washer and fully compress fingers. Remove adjusting screw, washer, and plate return spring or clip. Place ½" steel block under outer end of each finger. Back off compression nut slowly until release levers rise and contact steel blocks. Remove nut and compression washer, lift off cover. To remove release levers from cover, grind off one end of pin and drive out pin.

Clutch Springs: Three springs used Spring pressure should be as shown in tables below

1954-58 Spring Specifications

Model	Lbs. Pressure
Dodge (9251-12)	251 lbs. at 1 13/16"
Dodge & Plymouth (100052-2)	254-280 lbs. at 1 11/16"
Plymouth (9251)	222-246 lbs at 1 13/16"
Willys (Exc 8501-36, 39)	180-195 lbs. at 1 9/16"
Willys (8501-36,39)	180-203 lbs. at 1 9/16"
Willys (6-226 4WD)	220-230 lbs. at 1 9/16"
Willys (6-226 2WD)	239-264 lbs at 1 13/16"

1959 Spring Specifications

Model	No. & Color	Lbs. Pressure
Dodge	3 Pink	280 lbs. at 1 13/16"
Plymouth	3 Dark Blue	254-280 lbs. at 1 13/16"
Willys		
4 Cyl Utility	3	245-265 lbs. at 1 9/16"
Jeeps	3	220-230 lbs at 1 9/16"
4 Cyl Fwd Cont	3	220-230 lbs. at 1 9/16"
6 Cy 4-Whl Dr.	3	220-230 lbs at 1 9/16"
6 Cyl 2-Whl. Dr.	3	239-264 lbs. at 1 13/16"

1960 Spring Specifications

Model	No. & Color	Lbs. Pressure
Dodge Dart 6 Cyl	3 Aluminum	258-286 lbs at 1 53/64"
Plymouth 6 Cyl.	3 Aluminum	258-286 lbs. at 1 53/64"
Willys 4 Cyl		220-230 lbs. at 1 9/16"
Willys 6 Cyl 2WD		239-264 lbs. at 1 13/16"

R assembly: Assemble levers to cover, peen over ends of lever pins. Install pressure spring between lever and cover. Make sure springs rest on bosses of cover and are seated in the embossed seats of levers. Press down on release lever and then insert steel blocks under outer ends of levers. Place pressure plate on fixture and place cover assembly over the pressure plate Match up punch marks so parts are in original positions Place spacer (see below) on center screw of fixture. Install compression plate, self-aligning washer, thrust washer and compression nut on center screw. Tighten compression nut on fixture. Install washers and adjusting screws in pressure plate. Release fixture compression nut slowly and install pressure plate return springs.

Release Lever Setting: Install the clutch cover plate assembly on fixture and make certain that housing clamps line up with holes. With the spacer (see below), compression washer, self-aligning washer, and compression nut installed, tighten nut until release levers are completely compressed Install clutch housing clamps and tighten securely. Adjust clutch release levers until each of the three feeler gauges has the same slight drag when being pushed in and out. Tighten release lever screws to decrease drag or loosen them to increase drag Recheck adjustment of each lever, tighten locknuts

Release Lever Setting Spacer

Model	Spacer

Willys Return Clip Spring Installation—Engage slot on flat end of spring under head of release lever adjusting screw, engage loop on curved end of spring over ridge on outer end of release lever

►*INSTALLATION ON CLUTCHES IN SERVICE:* Clips can be installed by working through inspection hole in bell housing without dismantling clutch. *CAUTION*—Use string attached to clip to prevent it dropping down into bell housing during installation.

DRIVEN MEMBER: *S Car Mod l pag s for Part Nos. or facing specifications.*

BUICK (OWN) CROWN SPRING

1954-55 Series 40 (Synchro-mesh Cars)
1954 Series 50 (Synchro-mesh Cars)

►*1954-55 REPLACEMENT CLUTCH ASSEMBLY (Series 40 & 50):* New "finger type" Clutch Assembly, No. 1392653, similar to 1956 Series 40 Clutch is furnished for service to replace previous "Crown Spring" Clutch No. 1393485 (used on 1954-55 Series 40). Individual parts are still furnished for Crown Spring Clutches. New Release Bearing should be used with this replacement clutch as follows:

Replacement Clutch Release Bearing – When "finger type" clutch installed, it is recommended that new type Clutch Release Bearing, Buick Part No. 1310983, be used with this clutch. This bearing has flat face for release lever contact (previous type release bearing has rounded face).

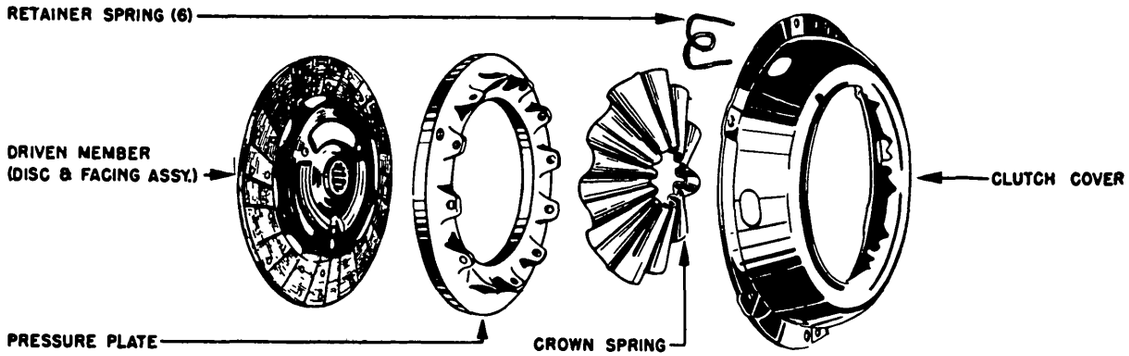
►**Excessive Pedal Pressure and Noisy Clutch Disengagement Correction:** If the clutch pedal pressure required to disengage clutch exceeds 35 lbs., check for dry release linkage and apply small amount of Lubriplate to clutch spring disc at points where it contacts cover. Check clutch release bearing support for correct assembly, brush Lubriplate on bearing surface between bearing retainer and support.

►**Clutch Dragging Correction:** If drag not caused by pedal free travel adjustment, remove clutch housing lower cover, hold pedal in disengaged position and check for clearance between crown spring disc and edge of cover with feeler gauge. Spring must contact cover at all points (clutch will not disengage properly unless firm bearing secured at all points). To correct this condition, disassemble clutch, place cover assembly on surface plate, check height of six ears to which retainer springs are hooked and bend ears so that distance from surface plate to upper edge of each ear is exactly 1⅝". Replace retainer springs if they are weak or distorted. CAUTION—Replace springs as complete set only (necessary to assure even spring tension).

DESCRIPTION: Single plate, dry disc, of new design with corrugated spring disc which replaces both pressure springs and release levers used on former clutch. Corrugations on disc engage ears on inner rim of clutch cover and lugs on pressure plate. Disc pivots on cover plate ears when it is flexed to release clutch, relieving pressure on pressure plate which is then pulled away from driven member by hairpin type retainer springs which pass through holes in pressure plate lugs and are hooked over cover ears.

REMOVAL: *See "Clutch" on car model page.*

DISASSEMBLY: Mark pressure plate, spring disc and cover. Use tool J-1039-2 to unhook retainer springs from the clutch cover ears working springs slightly toward center to permit tool engagement (do not hammer on tool which will distort cover), lift clutch cover off. Unhook retainer springs from spring disc by working one leg of each spring in through pressure plate lug toward center of clutch and other leg out, lift off spring disc, remove retainer springs from pressure plate lugs.



Clutch Cover Inspection—Check height of spring retainer ears by placing cover on flat surface and measuring from surface to top surface of each ear. Distance should be 1 5/8". Correct by bending the ears (*CAUTION*—use care not to crack or distort cover). Replace cover if cracked or distorted.

Crown Spring Inspection—Check for excessive flattening of the spring due to taking on a permanent set, by placing spring on flat surface and measuring height of top surface of spring at inner rim. Normal height is 1 13/16" and height should not be less than 1 11/16"

REASSEMBLY: Install the retainer springs in pressure plate lugs with curved legs of springs up toward spring disc (push one leg of each spring in toward center of clutch and position the other spring leg that it is just entered in hole in lug). Apply 'Lubriplate' lightly on spring disc at points where it contacts pressure plate and retainer springs (excess will ruin clutch facings), place spring disc on pressure plate, maneuver retainer spring loops over disc by turning springs so that they are properly aligned. Install cover, use special tools to engage retainer spring loops on cover ears. Make certain that marks on pressure plate, spring disc, and cover are lined up. This completes clutch assembly (no release lever adjustment, etc. required).

DRIVEN MEMBER: Both Borg & Beck and Long Driven Members used. Driven members serviced as an assembly and parts not furnished separately. When installing driven members, see that large washer or oil baffle is toward transmission.

See Borg & Beck and Long "CF" clutches for complete driven member data.

BUICK "CROWN SPRIN " CLUTCH

1954-55 BUICK (OWN) SINGLE PLATE

1954-55 Series 50 (Synchro-mesh Cars)
1954-55 Series 60 (Synchro-mesh Cars)

►CHANGES, CAUTIONS, CORRECTIONS

►**Excessive Pedal Pressure and Noisy Clutch Disengagement Correction:** If the clutch pedal pressure required to disengage clutch exceeds 28 lbs., check for dry release linkage and lubricate clutch pressure plate driving lugs as follows: Remove clutch housing lower cover, turn clutch so that driving lug is at bottom, brush small amount of 'Lubriplate' on each lug as pedal is being operated (lubricate all 3 lugs in same manner). If clutch still noisy, check clutch release bearing support for correct assembly, brush Lubriplate on bearing surface between release bearing retainer and support. Release lever pins that are dry and noisy can be corrected by spraying dry powdered graphite into pressure plate assembly (graphite will work into bearing when clutch is operated).

►**Clutch Rattle Correction:** Rattles when the engine accelerated with clutch disengaged (similar to noise caused by loose connecting rods or pistons) may be caused by excessive clearance between pressure plate driving lugs and cover. To correct this condition, remove lower cover, turn clutch so that driving lug is down, **hold clutch pedal in disengaged position,** prick punch trailing edge of lug in 3 places so as to swell lug and take up clearance. Clearance between lug and cover should be .005-.008". Correct each lug in same manner.

DESCRIPTION: Single plate, dry disc type. Clutch mounted in slight recess in face of flywheel with pressure plate lugs in grooves cut in flywheel rim so that drive transmitted directly from flywheel to plate. Clutch is actuated by three release levers pivoted on adjusting bolts in cover plate and linked to pressure plate by pins in lugs on plate. Servicing directions below apply to pressure plate assembly and need not be followed unless pressure plate, springs, or release levers to be examined or replaced.

REMOVAL: *See "Clutch" on car model pages.*

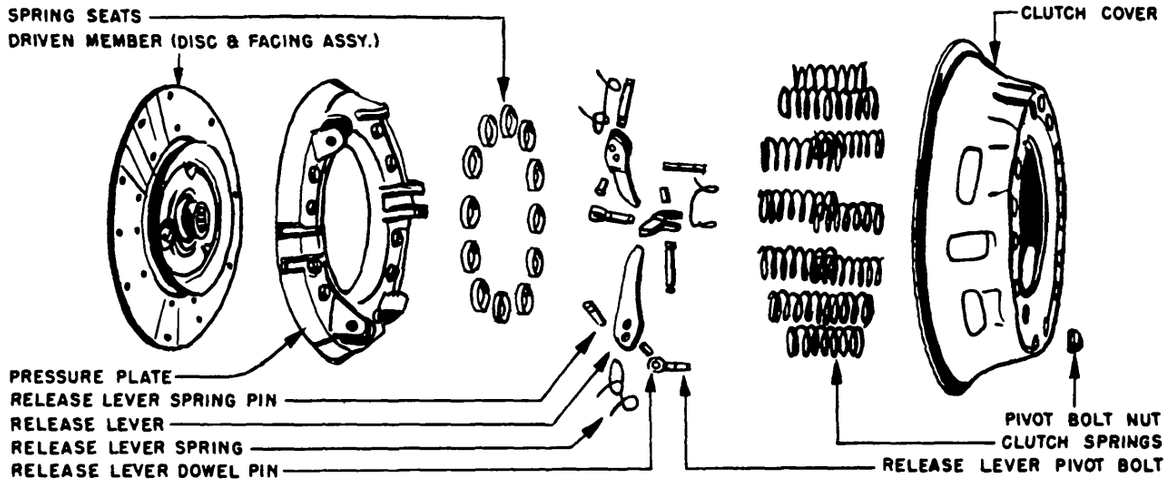
OVERHAUL: Mark all parts before dismantling and reassemble in same position to maintain balance.

Disassembly: Place pressure plate assembly on arbor press, place block on cover (clearing release lever adjusting nuts) to take pressure, compress cover slightly, remove adjusting nuts, release pressure slowly. Lift off cover. This will expose all parts for inspection. Replace worn parts, check clutch springs.

Clutch Springs: Check spring pressure and replace if weak or burned. Twelve springs (3 groups of 4) used. **Spring Pressure**—135-145 lbs. at 1¾" spring length.

Assembling:—Place pressure plate on arbor press. Install pressure springs on plate. Place cover in position on springs, install guide pins on release lever adjusting bolts. Compress cover slightly guiding adjusting bolts through holes in cover, install adjusting nuts on bolts, remove assembly from arbor press.

Releas Lever Height Adjustment:—Assemble gauge plate in flywheel in place of driven member, centering gauge in clutch with lugs on plate under release levers. Place short straightedge on top of gauge hub,



CONTINUED ON NEXT PAGE

1954-55 BUICK (OWN) SINGLE PLATE (C nt.)

or use dial indicator & service tool J-1013 mounting indicator on clutch so as to contact release lever tips. Turn adjusting nut until release lever just contacts straightedge or dial indicator and all levers are equal within .005", lock adjusting nut by crimping thin edge against flat on screws, using large pliers.

Gauge Plate—No. J-1036.

DRIVEN MEMBER: Spring dampener type hub used on all models. When replacing facings, drill out old rivets to avoid distorting clutch disc when removing old facings. Both Borglite type and new Long type Driven Members are used. Both types have woven facings which are grooved for quicker release. Driven members are balanced by use of extra rivets or clips on driven member hubs and these balance weights should not be removed. Driven members are serviced as an assembly (parts not furnished separately). CAUTION—Install driven member with large oil baffle toward transmission.

BUICK "SINGLE PLATE" CLUTCH

1956 BUICK (OWN)

1956 Series 40

NOTE - This clutch is a Long 11LC No. 265226

►CHANGES, CAUTIONS, CORRECTIONS

► *CLUTCH EQUALIZER INTERFERENCE CORRECTION (Early Cars).* To correct, grind approximately 1/8" off end of equalizer and remove 1/4" off each end of reinforcement ridge. Correction has been made in later production cars.

► *CLUTCH RELEASE LEVER PRODUCTION CHANGE (Elimination of Release Lever Adjustment After 1st 5000 Cars).* First 5000 cars had release lever adjustment and can be identified by buttons threaded into inner ends of release levers. All later release levers have buttons welded into release levers and are not adjustable.

DESCRIPTION: Single plate, dry disc type.

RELEASE LEVER ADJUSTMENT (1st 5000 Cars): Mount dial indicator on Support J-1013, set support on flat surface, press indicator stem down against surface until indicator hand has made one revolution, then tighten indicator to support and set indicator at zero. Place adjusting gauge, J-1036 on spare flywheel, then place clutch assembly on gauge so release levers are directly above machined bosses of gauge. Install cover bolts and tighten each one several turns at a time until all are uniformly tight. Place support and indicator on machined hub of gauge so that indicator bears on adjustable button. Indicator should read plus or minus .031" and release levers should read within .031" of each other. Adjust buttons to bring levers within limits. Stake buttons to release levers and recheck settings.

RELEASE LEVER CHECK (After 1st 5000 Cars - Non-Adjustable Levers): Proceed as in "Release Lever Adjustment" above. If variation between levers exceeds .031" or any part of clutch assembly is defective, clutch pressure plate and cover assembly must be replaced as a unit.

REMOVAL: *See "Clutch" on Car Model pages.*

OVERHAUL: Clutch cover and pressure plate serviced by replacement.

INSPECTION: Wash all metal parts of clutch, except release bearing and driven plate, in suitable cleaning solution.

Flywheel & Pressure Plate - Examine friction surface for scoring or roughness. Smooth with fine emery cloth, but if deeply scored or grooved, replace part.

Clutch Cover - Inspect cover for cracks or distortion. Check clearance between pressure plate driving lugs and edges of slots in cover with feeler gauges. Clearance should be .005-.008" (excessive clearance may cause rattle when engine intermittently accelerated with clutch disengaged).

Driven Plate - Inspect condition of facings, for loose rivets, broken or very loose torsional springs, and flattened cushion springs. Replace as required.

Driven Plate Run-Out Check - Slide driven plate, **front side first,** over transmission main drive gear until it is tight on spline, then set up dial indicator to bear against plate facing. While holding firmly against front end of main drive gear to take up play in main drive gear bearing, slowly rotate driven plate and observe amount of run-out. If run-out exceeds .025", replace driven plate.

Bearings - Inspect for scoring or excessive wear on front contact face. Test for roughness of balls and races by pressing and turning front race slowly. Inspect main drive gear pilot bearing in crankshaft. Replace if rough or worn, using Puller J-164 for removal.

DRIVEN MEMBER: Long No. CD873. Buick No. 1391632.

BORG & BECK (CORVAIR)

Car Model	Borg & Beck Assy. No.
Corvair	361537

DESCRIPTION: Single plate, diaphragm spring type with starter ring gear mounted on clutch cover. Diaphragm spring is riveted assembly with cover and cannot be disassembled. Pressure plate is bolted to three drive-straps riveted within cover and can be removed.

OVERHAUL: *NOTE* - Servicing is limited to removal of pressure plate and inspection of cover assembly and plate for wear or damage. Parts are not furnished and cover assembly should be replaced as a unit.

Disassembly: Mark cover and pressure plate to insure reassembly in same relative position. Working through slots in cover, take out bolt in each driving strap, remove retracting springs (under bolt head on each driving strap), lift cover off.

Reassembly: Reverse disassembly procedure. Tighten drive strap bolts to 15-20 ft. lbs. torque.

DRIVEN MEMBER: *See Car Model pages for data.*

Ⓒ - Plus or Minus 5 lbs ② - Plus or Minus 6 lbs. ③ - Plus or Minus 7 lbs

BORG & BECK MODELS (Continued)

consist of surface plate(duplicates the driving surface of flywheel), clamp screws to clamp clutch cover against plate, arbor press to compress springs in dismantling clutch, and gauge standard for use in setting up release levers.

DESCRIPTION: Single plate, dry disc type. Three release levers, mounted on bolts piloted in pressure plate and retained in clutch cover, actuate clutch struts which provide "knife-edge" action.

Semi-centrifugal Clutch Note - These clutches have three roller assemblies in grooves in pressure plate directly under the clutch cover. Centrifugal action on these rollers increases the pressure plate load as the engine speed increases.

REMOVAL OF CLUTCH: *See "Clutch" on car pages.*

►*MERCURY & PONTIAC CLUTCH OVERHAUL NOTE:* Parts are not furnished and these clutches are serviced by replacement.

OVERHAUL: Mark all parts before dismantling clutch and reassemble in same position (necessary to maintain balance). Replace grooved, checked or warped pressure plates. Replace springs when pressure plate discolored from heat.

Disassembly: Place clutch on fixture or arbor press (support pressure plate under release levers), place block across cover resting on spring bosses, compress cover slightly, remove metal staking in adjusting nuts by running hacksaw blade through slot, remove nuts. Release pressure slowly, remove cover and springs. Remove release levers by grasping lever and eyebolt between thumb and forefinger, so that inner end of lever and upper end of eyebolt are pressed together, lift strut over ridge in end of lever(press lower end back against lug), lift lever and eyebolt out.

Reassembly: Place pressure plate on fixture or arbor press supporting plate under release lever lugs. Install lever, eyebolt and strut assemblies by reversing removal procedure. Place pressure plate springs on the plate, and install anti-rattle springs in cover. **(Chevrolet** - Install centrifugal rollers). Place cover on pressure plate. Make certain that springs are seated in cover recesses and anti-rattle springs in place on release levers. Compress cover slowly and guide eyebolts through holes in cover. If assembly made in fixture, use clamps to clamp cover flange to plate at mounting holes. Install eyebolt nuts and turn nuts down flush with head of bolt. Compress and release clutch several times to seat all working parts. Then adjust release lever heights.

Clutch Springs: Note spring color and install in same relative position (groups of two different springs used on some clutch models). Springs should check with table below. Replace springs if weak or burned or if clutch has been subjected to excessive heat.

Release Lever Adjustment (With Borg-Warner Universal Fixtures UF-300, 400): Special lands must be installed on fixture under pressure plate lever lugs. Set adjusting arm on adjusting sleeve so that height of lower side arm above bottom of sleeve is correct for each model (see table below). Install indicating plate on levers. Adjust each lever so that it just contacts indicating plate or adjusting arm, lock lever adjusting nuts by peening nut against notches in eyebolt.

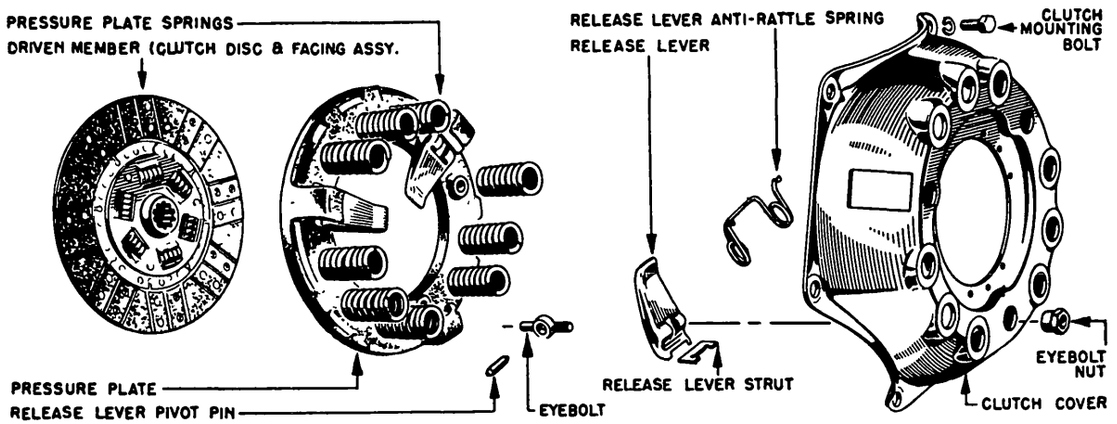
① - With three 3J Land and 3X Indicating Plate.
② - UF-300 - With three 3J Land, 3X Indicating Plate, six 3K7 Height Sleeves, and four Bars (5/16"x5 1/4" Keystock) on Flange Bridging Holes not in line with slots. UF-400 - With three 3J Lands and 3X Indicating Plate.
③ - 1/16" higher with Baffle.



Rear Release Lever Adjustment (Using Gauge Plate): Use gauge plate indicated in table below and install clutch on flywheel with gauge plate in place of regular driven member, with lugs on gauge directly under release levers. Use short straightedge placed on edge on gauge plate hub and adjust release levers so they just contact edge of straightedge for all models marked "flush" in table. If lever setting marked "high", a cut-out or step must be made in edge of straightedge at one end so that levers can be set higher than hub. If lever setting marked "low", cut-out or step should be cut in gauge hub end of straightedge so that end extends below hub. Cut-out or step should be in the amount "high" or "low" indicated in table. Lock adjustment by peening nut into notches in eyebolt.

Release Lever Settings (Using No. 4234 Gauge Plate)

Clutch Model	① Lever Height
8A7	② 3/16" Low

BORG & BECK CLUTCH ASSEMBLY (TYPICAL)

BORG & BECK MODELS
(C ntinued)
RELEASE LEVER ADJUSTMENT
(Using Gauge Plate)

Use gauge plate indicated in table below and install clutch on flywheel with gauge plate in place of regular driven member with lugs on gauge directly under release levers Use short straightedge placed on edge on gauge plate hub and adjust release levers so they just contact edge of straightedge for all models marked "flush" in table (If lever setting marked "high" a cut-out or step must be made in edge of straightedge at one end so that levers can be set higher than hub, if lever setting marked "low" cut-out or step should be cut in gauge hub end of straightedge so that end extends below hub Cut-out or step should be in the amount "high" or "low" indicated in table) Lock adjustment by peening nut into notches in eyebolt

RELEASE LEVER ADJUSTMENT
(C-585 & C-585A Fixture)

With C-585 & C-585A Clutch Fixture—On this fixture feeler gauges are located in base of fixture under the clutch assembly Install the clutch assembly on fixture with release levers directly above feeler gauges (on 4-lever type 11" clutches install clutch with two levers directly over two of the feeler gauges, adjust these levers then rotate clutch so that other levers are over feelers and adjust these levers) Place correct spacers on center screw of fixture (see table below) install compression plate on center screw making certain that it rests directly against all release fingers (plate can be reversed to provide proper clearance on all models) install self-aligning washer plain washer and compression nut Tighten compression nut until clutch fully compressed install clutch housing clamps over cover bolt holes and tighten clamps securely Adjust each release lever adjusting nut until slight drag secured on each feeler (all feelers alike) lock adjusting nuts and recheck adjustment

Release Lever Settings (Using Gauge Plate)

H.D. Heavy Duty **F.C.** Forward Control **O.D.** Overdrive

►CHANGES, CAUTIONS, CORRECTIONS

►**Clutch Rattles at Idling Speed (Pedal Depressed & Clutch Disengaged) Correction:** May be due to insufficient tension of retracting springs and can be corrected without removing clutch from engine as follows: Remove clutch housing underpan, turn flywheel until one retracting spring is at bottom, remove bolt (work through hole in side of cover), withdraw spring, install new spring in same manner. Replace all three retracting springs in this way. If new springs do not correct rattles, check clearance between pressure plate lugs and edge of clutch cover slot. Clearance should be .002-.008" and clutch cover assembly or pressure plate should be replaced if clearance exceeds .010".

►**Clutch Balance Caution:** When installing pressure plate make certain that '0' marks on one lug of plate and on clutch cover flange are lined up. When installing clutch in engine, line up 'X' marks on clutch cover and flywheel. This is necessary to maintain clutch balance.

DESCRIPTION: Single plate dry disc type with a diaphragm spring (replacing conventional clutch release springs and release levers) Diaphragm spring is shaped like a dished washer, with inner rim slotted to form 18 release fingers and is pivoted on inner and outer pivot rings, mounted on 9 bolts in clutch cover *NOTE - The 348" Engine (1959) & 283" Engine with 4-Bbl Carb & 348" Engine (1960) clutches have a new design The clutch is semi-centrifugal with 6 of the fingers (18 total), bent upward with weights at outer ends to provide the centrifugal action*

REMOVAL: *See "Clutch" on car model pages.*

OVERHAUL: Manufacturer recommends the use of Clutch Pilot Tool K-411, to support clutch during disassembly, and Clutch Assembling Fixture J-1113, to compress diaphragm spring when disassembling and assembling pressure plate and cover assembly.

Retracting Spring Replacement. Does not require dismantling clutch. Remove clutch housing underpan, crank engine over until retracting spring bolt appears in lower opening, remove bolt, withdraw retracting spring, install new spring in same manner. Replace other retracting springs (3 used) in same manner.

Disassembly: Take out screws and remove the three retracting springs through slots in cover (screws accessible through holes in side of cover), make certain that one pressure plate lug and cover marked to insure correct reassembly, remove pressure plate.

Servicing: Wash all parts except the throw-out bearing in gasoline (see Caution below), examine pressure plate and flywheel face for scored or rough surface, check pressure plate drive lugs for burrs, see that lugs move freely in cover slots and that clearance in slots is .002-.008" (replace pressure plate or cover if clearance exceeds .010"). Check diaphragm spring and pivot rings for distortion or cracks.

Reassembly: Reverse disassembly directions.

DRIVEN MEMBER: Different diameters used Replace with same size removed

INSTALLATION: Line up 'x' marks on flywheel and cover, install cover bolts and tighten evenly, one turn at a time, to prevent distorting cover

HUDSON (OWN)

Models 4D, 5D, 7D (1954)

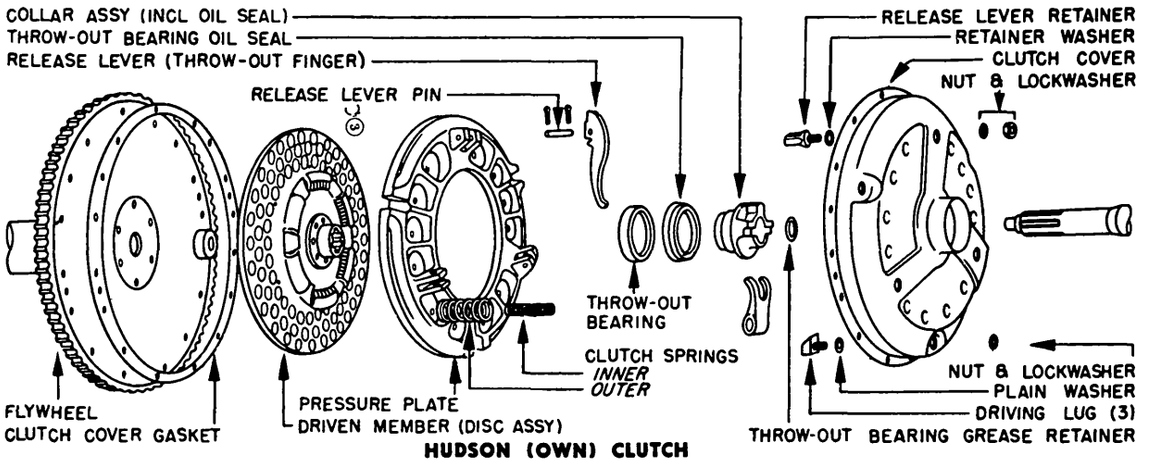
DESCRIPTION: Single plate cork insert type operating in oil. Mounted on flywheel by 16 capscrews in cover flange. Gasket used under cover flange to secure oil-tight joint and oil seal mounted on throw-out collar to retain clutch lubricant. Clutch actuated by 3 clutch fingers pivoted on retainers bolted to cover and linked to pressure plate by pins.

REMOVAL: *See "Clutch" on car model page.*

OVERHAUL: Clutch cover need not be dismantled when replacing driven member unless springs are to be tested or replaced, pressure plate replaced, or other service work required. ***Check cover to determine whether disassembly required as follows:***

Checking Cover Assembly—Mount cover on flywheel or base plate with standard driven member (.200-.213" thick) and one gasket (.028-.032" uncompressed thickness) under flange (CAUTION—cover must be held by pressure on flange—not on cover flat or hub). Measure distance from contact surface of lowest clutch finger to top edge of cover hub. This distance should be 1¼-1½". If less than 1¼", clutch will perform satisfactorily if all fingers clear hub by at least ⅛". If distance greater than 1½", cover is distorted or fingers and retainers are worn. Dismantle for inspection as follows:

Dismantling:—Check punch marks near outer edge of pressure plate in line with mark on cover flange or make new marks to insure reassembly in same position. Place clutch assembly on special clutch fixture (#J-298-H) or in arbor press supporting pressure plate so that cover is free. Compress cover slightly, take off 3 nuts on clutch finger retainer bolts on cover, release pressure slowly, lift cover off.



Clutch Cover: Inner surface must be flat and free from scores at finger retainer holes. Front face must be flat within .005" when checked on a surface plate. Measure distance from face of cover flange (mounting face) to retainer washer seat on inner face of cover. This distance must be 2.350" minimum, 2.370" maximum, and equal within .008", measured ⅛" from edge of finger retainer holes. Straighten or replace cover if outside these limits.

►***CAUTION—If cover hub bore considerably worn or scored, check engine rear support plate, flywheel, and bell housing for misalignment or shaft eccentricity.***

Clutch Fingers & Retainers: Check fingers at contact points and pin bore for wear or uneven bearing surfaces. Check retainers for wear at finger contact point in slot. Replace retainers if bearing area grooved deeper than .005". NOTE—Retainers can be continued in service by rotating them 180° when installing so that unworn portion contacts finger lobe.

Pressure Plate:—Examine plate, replace if scored. Check for warping (particularly if plate 'blued' due to overheating). Replace if warped more than .010".

Clutch Springs:—Special combinations of large (outer) and small (inner) springs used on different models (inner springs not used on all models). Check springs and replace if pressure less than service limit in table below. Springs should be replaced if pressure plate 'blued' indicating overheating in service.

HUDSON (OWN) CLUTCH

SPRING SPECIFICATIONS

Spring Part No.	①Pressure & Length
155224 (Inner)	75-85 lbs at 1⅝"
166250, 51 (Outer)	130-140 lbs at 1⅝"

	Outer Springs		Inner Springs	
Car Model	No.	Part No.	No.	Part No.
Wasp, 4D ①	9	166250	6	155224
Optl. 4D	12	166251	3	155224
All Others ②	12	166251	3	155224

① - 9" Clutch. ② - 10" Clutch.

Assembling:—Check clutch throw-out fingers, see that they are straight and do not show wear at tip or retainer lug. Replace retainer washers if necessary. Place pressure plate on fixture with face down. Assemble springs, clutch fingers, retainers and retainer washers on plate. Place cover on top of pressure plate assembly (lining up marks on cover and plate), compress cover slowly, guiding retainer bolts through holes in cover, install lockwashers and nuts on each finger retainer, tighten retainer nuts evenly to 40-45 ft. lbs. after cover has been fully compressed. Remove assembly from fixture and check alignment of clutch fingers in retainers, turn retainers with heavy duty end wrench until fingers centered sideways in retainer slots. See that shoulder on retainers fully seated on wall of cover. Check clutch finger heights with clutch installed on flywheel (below).

Clutch Finger Alignment: With clutch installed on flywheel, check distance from contact end of lowest clutch finger to top edge of cover hub. This distance should be within 1¼" to 1½". If less than 1¼", clutch will operate satisfactorily providing fingers clear cover hub by at least ⅛". If distance greater than 1½", check cover for distortion (see Clutch Cover). Adjust all clutch fingers as follows:

Clutch Finger Adjustment—Use special finger adjusting gauge (#J-774) resting gauge on clutch cover so that pin is directly above clutch finger tip. Turn thumbscrew down until pin contacts finger. Repeat at other clutch fingers to secure final gauge setting equal to lowest finger. If any finger more than .030" higher than others, adjust by installing thin (.005") washer between cover and retainer for this finger. If fingers more than .010" but less than .029" higher than others, turn gauge to higher finger, strike end of retainer bolt with soft hammer until gauge bar rests squarely on cover hub. With final setting, gauge bar should rest squarely on hub over all fingers and clearance between pin and end of thumbscrew must be less than .010" (all fingers equal within this amount—check with feeler gauge).

Throw-out Bearing & Oil Seal:—Insert 1/3 pint Hudsonite through clutch hub before installing throw-out collar assembly. Oil seal is pressed on collar behind throw-out bearing. When installing new oil seal, press firmly near inner diameter (pressure at point near rim may distort outer stamping and allow inner stamping and oil seal leather to revolve with shaft, this will cause noise similar to noisy throw-out bearing). Use arbor press to install throw-out bearing (do not drive on). See that bearing revolves smoothly and that oil seal inner stamping is tight in outer stamping before installing collar in clutch cover.

CAUTION—Install new grease retainer in annular recess in throw-out bearing when assembling bearing on collar. Soak this retainer and oil seal in engine oil for at least 30 minutes before installing.

DRIVEN PLATE: Plate has a spring-dampener type hub and facing consisting of cork inserts. Examine driven member, see that plate runs true and do not have appreciable free play. See that hub is not warped or distorted, and that springs in hub splines are not worn and are free from burrs. Corks must be in good condition. Black glaze indicates use of wrong lubricant. Soak driven plate in Hudsonite and clean corks, or replace driven member.

1954 Driven Member Specifications

Car Model	Outer Diameter	No. of Corks
Wasp, 4D	9"	90
Optl., 4D	10"	108
All Others	10"	108

INLAND

Pontiac 6 & 8 Cyl. Models (1954-56)

►CHANGES, CAUTIONS, CORRECTIONS

►**Pontiac Clutch Poor Release Complaints**—May be caused by the anti-rattle spring wearing into plate and binding at end of spring. To correct this condition, examine pressure plate and spring for indication of interference. Smooth up pressure plate to provide good bearing surface for face of spring. See that spring does not have end thrust on pressure plate lug (shorten end of spring if necessary). Lubricate spring with Lubriplate when reassembling. CAUTION—Driving lug slots must not be widened to correct poor release. Clearance in excess of .005" at either side of lug will cause clutch noise and roughness.

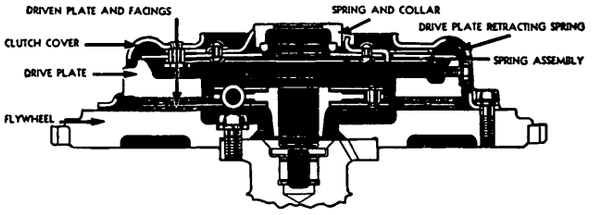
DESCRIPTION: Single plate, dry disc, with diaphragm spring disc which takes the place of both pressure plate springs and release levers.

1954-55 Pontiac 8 Clutch - Larger 10" type may be identified by greater diameter and six mounting bolt holes in cover.

Pontiac Anti-Rattl Spring—Consists of a flat spring installed between the pressure plate and the clutch cover in one of the cover holes adjacent to the '0' balance marked lug hole. This anti-rattle spring should be wired in place before pressure plate is removed and must not be installed in any other position. CAUTION—Changing position of anti-rattle spring will upset clutch balance.

Clutch Applications

Pontiac Cover Assy.	Part No.
1954 Sed. Del., Taxi, H.D.	758645
1954 6 Cyl Std.	755959
1954 8 Cyl. Std.	757370
1955-56 8 Cyl. Std.	758513



REMOVAL: *See "Clutch" on car model page.*

OVERHAUL: *CAUTION - Clutch cannot be disassembled (riveted construction).*

DRIVEN MEMBER: Long "CF" type used on all models. *See "Long CF" Clutch Data.*

LONG MODEL 8½

Car Model	Long Assy. No.	Ford No.
Comet	200013	CODD-7563-B
Falcon	200013	CODD-7563-A

DESCRIPTION: Single plate, dry disc type. Three flat release levers extend through slots in cover and engage slots in pressure plate bosses. Pressure plate springs are installed between pressure plate and cover in groups between the release levers.

OVERHAUL: *CAUTION - Parts are not furnished and manufacturer recommends that clutch not be disassembled.* Replace pressure plate and cover assembly if release levers do not operate freely or if lever heights are not equal. See Release Lever Checking (below).

Release Lever Checking: Assemble pressure plate and cover assembly on flywheel with .250" shim installed in place of regular driven member. Use depth gauge or dial indicator to measure height of inner end of each release lever. All levers must be equal within .031". If lever variation greater than .031", replace pressure plate and cover assembly.

DRIVEN MEMBER: *See Car Model pages for data.*

ROCKFORD 8½RM

MODEL 8½ RM

WILLYS	Rockford No.
All Models Exc. 6-226 Eng. (1954-60)Ⓒ	165317

Ⓒ - Auburn Clutch also used.

DESCRIPTION: Single plate, dry disc type. Clutch is three-lever type with six springs mounted in pairs adjacent to levers.

REMOVAL: *See "Clutch" on car model pages.*

OVERHAUL: Clutch cover and pressure plate assembly need not be disassembled when replacing driven member unless springs are to be replaced or other service work performed.

Disassembly: Place cover assembly in arbor press, compress cover slightly, remove release lever pivot pins, unhook lever springs, remove levers. Release pressure slowly, lift off cover.

Clutch Springs: Check springs and replace if weak or burnt. Springs should check as follows:

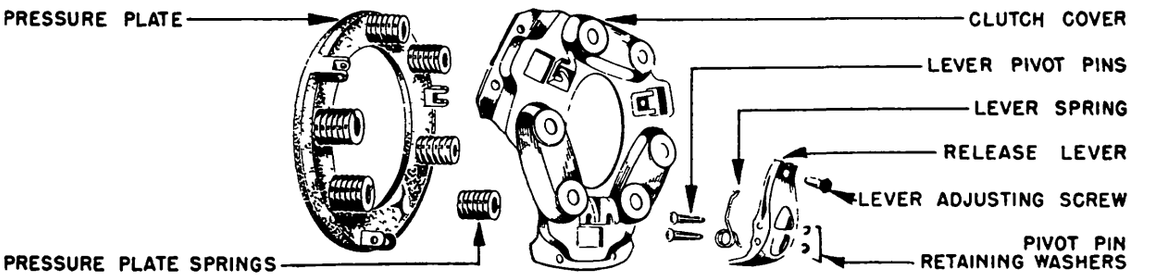
Spring Specifications

Cover Assy.	Spring Part No.	Pressure & Length
R3030	M-2317-4	140-150 lbs. at 1 7/16"
165317	105348	170-180 lbs. at 1.312"

Reassembly: Reverse disassembly procedure, make certain that pressure plate springs seated in pressure plate and cover and that lever springs correctly installed. Check lever heights after assembly completed.

Release Lever Setting: Manufacturer recommends use of Borg-Warner Fixture UF-300 or 400 for lever adjustment. Lever setting should be as follows:

Release Lever Settings



Clutch Assy.	Release Lever Height
R3030	2 13/32"
165317	Ⓒ 2 5/16"

Ⓒ - Use only 3 clamps on UF-300 Fixture.

DRIVEN MEMBER: Borg & Beck "Borglite" type with spring dampener hub. *See car model page for facing specifications.*

DESCRIPTION: Single plate dry disc type Release levers formed with weight on outer ends which increases pressure on driven member as engine speed increases. Levers pivoted on pressure plate on needle bearings with fulcrum located in yoke support on cover plate. Hardened-steel screw contact provided on lever tips.

REMOVAL OF CLUTCH: *See "Clutch" on car page.*

OVERHAUL: *NOTE - Car manufacturers (Buick, Eds l, Ford) do not recommend Clutch Cover & Pressure Plate Assembly overhaul. On these models, if l ver height does not meet specifications shown in "Release Lever Setting" table or if l vers do not operate freely without bind, replace th ass mbly.* Mark all parts before disassembly and reassemble in same relative positions.

Clutch Fixture Note: Manufacturer recommends use of Borg-Warner Universal Clutch Fixture UF-300 or UF-400 for all servicing and rebuilding operations.

Disassembly: Place clutch on fixture (supporting pressure plate on special lands under lugs) or arbor press. Compress cover plate slightly, take out assembly screws (lever yoke mounting screws) on cover, release pressure on cover plate slowly, lift off plate. Note whether washers used on yokes under assembly screws (these washers must be reinstalled if old pressure plate used again). See special directions below on removing and reinstalling release levers.

Pressure Plate. Pressure plate refacing by grinding or turning down on lathe will throw release levers out of adjustment. If pressure plate being refinished remove .020" from face and install spacer washer .015" thick on release lever yoke under cover. *NOTE*–If washers are found on release lever yokes under cover when clutch disassembled, replace these washers (if old pressure plate used) or discard washers (if new pressure plate installed).

Clutch Springs: Pressure springs should check with table below. Replace springs if weak or burned or if clutch has been subjected to excessive heat.

① - Plus or minus 5 lbs. unless otherwise specified.
② - Plus 3 lbs. or minus 5 lbs.
③ - Plus or minus 2½ lbs.

Release Lever Assembly: Mount lever yoke on release lever, fasten by inserting flat-sided lever pin (flat side out or toward cover) and roller (place roller on flat side of pin). Insert lever in pressure plate lug, use roller pin sawed off to length of lever width as a guide and insert needle bearings, insert roller pin, pushing guide pin out, lock both lever pins with cotter pins. Thread release lever adjusting screws in ends of levers, turning screws down completely.

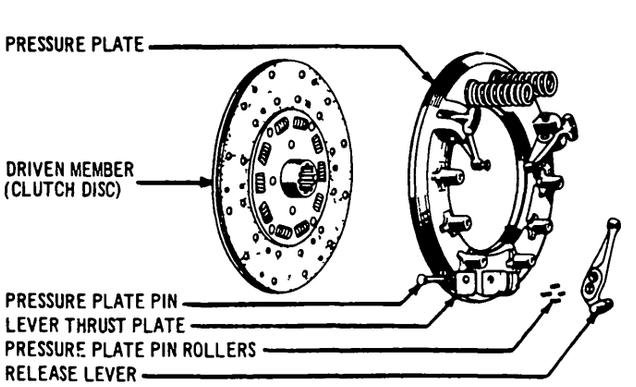
Assembly: Place pressure plate on fixture or arbor press. Assemble pressure springs, locator washers or insulator washers on plate, place washers on lever yokes (if washers used previously and old pressure plate being used). Place cover plate in position (lining up marks made before dismantling), compress cover slowly guiding lever weights through holes in cover and lining up yokes under cover plate holes. See that pressure springs are seated, insert cover screws in yokes, using lockwasher under screw head, tighten screws securely. Compress and release clutch several times (using weight on release levers) to seat all parts. Then adjust release lever heights.

Release Lever Adjustment (on Fixture): Place special lands on fixture under pressure plate lugs, assemble lever adjusting arm and sleeve setting bottom of adjusting arm correct distance as shown in table (all figures plus or minus 1/32") above bottom of sleeve and lock the adjusting arm with the thumbscrew. Swing arm over each release lever in turn, back off adjusting screw on tip of lever until rounded screw head just contacts arm, lock screws by inverting clutch so that screw head is supported and stake or peen lever into adjusting screw slot. Do not disturb lever yoke screws when making this adjustment.

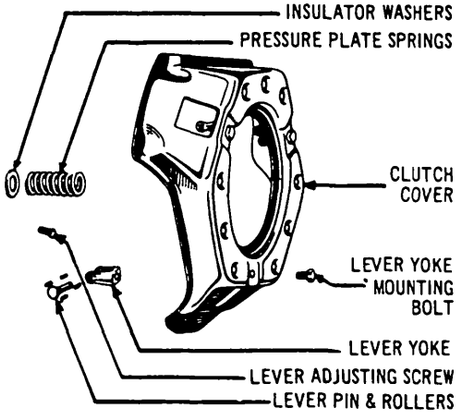
Release Lever Checking & Adjustment (Without Fixture): Check lever heights as follows (adjustment not recommended on Edsel & Ford clutches).

Buick - Mount clutch assembly on spare flywheel with Adjusting Gauge J-1036 installed in place of regular driven member. Assemble dial indicator on Support J-1013 and zero the indicator as follows: Place support on flat surface, press indicator down until pointer has turned approximately one revolution, tighten indicator on support and zero the pointer. To check release lever height, place support and indicator on gauge hub with indicator stem bearing on inner end of release lever. Indicator pointer should turn one revolution and read within plus or minus .031". All levers must also be equal within .031". Adjust levers as directed under "Release Lever Adjustment (On Fixture)" above.

Ford - Mount clutch assembly on spare flywheel with three .250" thick spacers (drill rod or precision washers may be used) in place of regular driven member (*NOTE* - Place spacer under each release lever). Use dial indicator to measure lever heights. All levers must be equal within .031". Replace pressure plate and cover assembly if greater variation noted.



Oldsmobile - Install special lever setting gauge J-4389 on flywheel in place of driven member, placing gauge so that lugs are under release levers and gauge is centered in clutch. Tighten all clutch cover bolts evenly. Place short straightedge across center of gauge (for positioning levers). Bearing surfaces of all levers should be from .0000" to .0625" below level of gauge center boss and all levers must be equal within .015". Adjust levers as directed under "Release Lever Adment (On Fixture)" above.



DRIVEN MEMBER: *See Car Model pages for data.*

① - Used with "Power-Lock" Differential only.
② - Used in partial production. *For other type rear axl , s "1955-57 Hudson, Nash, Rambler Hypoid".*
③ - Used in partial production on L6-226 4WD Jeep Trucks between 1954 and 1958. *For other type rear axl , see "Timk n S mi-Floating".*

►CHANGES, CAUTIONS, CORRECTIONS

►*1954-60 LINCOLN, 1954-56 MERCURY, 1954-56 FORD STATION WAGON, SEDAN DELIVERY & F-1 TRUCK: S e Ford, Lincoln, M rcury Rear Axle.*

►*CHEVROLET & WILLYS 4-WHEEL DRIVE FRONT AXLE OVERHAUL NOTE: Front axle overhaul procedures ar th sam as f r r ar axles*

►*AXLE RATIO CHANGE CAUTION: Use correct differential cas if ring g ar and pinion ratios changed.*

►*STUDEBAKER PINION SEAL LEAKAGE CORRECTION: Us a n n-hardening sealer similar to Permatex No. 2 b tw n seal and housing.*

►*WILLYS 4-WHEEL DRIVE FRONT END CHATTER CORRECTION:* This condition is due to turning angle being excessive and can be corrected by breaking the weld on stopscrews mounted on axle and readjusting turning angle to proper specifications as follows: **29°** (Except CJ-3B, CJ-5, CJ-6 & FC-150). **27½°** (CJ-3B, CJ-5, CJ-6). **27°** (FC-150 with 48" Tread). **29°** (FC-150 with 57" Tread).

►*WILLYS PINION SHAFT OIL SEAL DRIVER TOOL W-147 MODIFICATION FOR USE WITH LATEST TYPE PINION SHAFT OIL SEAL:* To prevent damage to seal during installation, increase outside diameter of tool recess from 1.975" to 2.031". Modified tool can be used on both early and later type seals.

DESCRIPTION: Hypoid gear type with semi-floating axles (Exc. Model 70 rear axles and axles used with front wheel drive units), full-floating axles (Model 70 and models used with front wheel drive units). Rear wheel bearings are roller type on all semi-floating axles except the model used on 1959 Chevrolet ½-Ton Truck which is ball bearing. The differential case used with Model 70 axle is "split type" case and contains four differential pinions.

►*REAR AXLE ASSEMBLY IDENTIFICATION NOTE: Spicer Model number is stamp d on one of th rear axl housing w bs. S Car Pages for axl model application.*

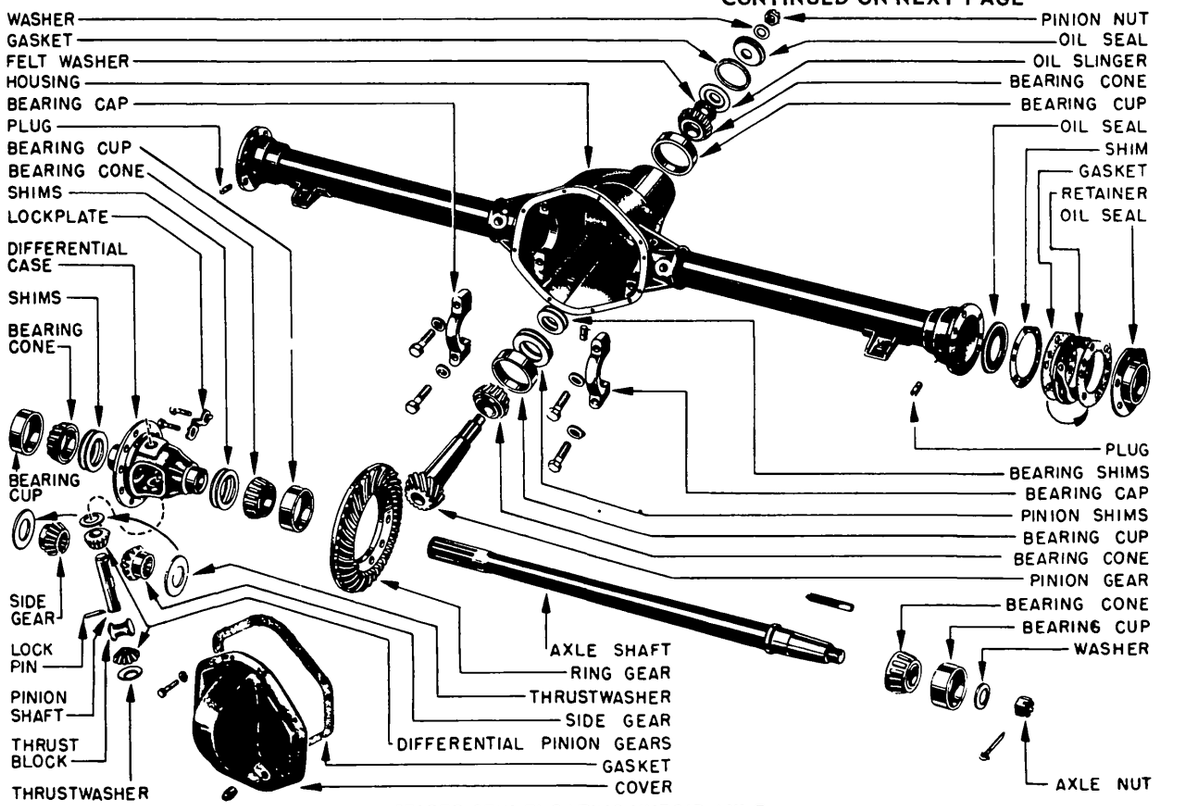
REAR AXLE ASSEMBLY REMOVAL: *Se "R ar Axle" on Car Model pag s.*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Mod l pages.*

AXLE SHAFT ENDPLAY (WHEEL BEARING) ADJUSTMENT: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT OIL SEAL REPLACEMENT: Rear Axle - On all models (Exc. Studebaker & Packard), pry old seal out of housing. On Studebaker & Packard, use Oil Retainer Remover Tool J-943 to remove seal. To install seal, soak seal in oil for 10 minutes, then coat outer surface of seal with Permatex and tap seal into bore using Tool J-2554 (Chevrolet); J-8092 & J-270-13 (Studebaker & Packard); W-186 (Willys) or other suitable tool.

Front Axle (Willys 4-Wheel Drive): With differential case assembly removed from housing, pry old seals out of inner ends of axle shaft tubes, then use Tool W-128 to install new seals.



Front Axle (Chevrolet Truck): With differential assembly removed from housing, pry out old seals or drive them inward into housing. Install new guides in tubes, then lubricate new seals and install in tubes with lip of seal inward toward housing.

PINION BEARING OIL SEAL REPLACEMENT: Disconnect rear universal joint at pinion shaft companion flange, then remove pinion shaft nut and washer and remove companion flange with a suitable puller. *NOTE - On Hudson & Nash models, see "Torque Tube & Propeller Shaft (Hudson & Nash)" above.* Remove old seal, then install a new seal by tapping it into place with Tool J-6419-5 (Chevrolet); J-892 & J-2037 (Studebaker & Packard); W-147 (Willys). Install oil deflector, companion flange, washer, and pinion shaft nut. Tighten nut to 200-220 ft. lbs. (Chevrolet); 140-180 ft. lbs. (Studebaker & Packard); 140-180 ft. lbs. (Willys except Model 70 axle); 225-275 ft. lbs. (Willys Model 70 axle).

REAR WHEEL BEARING REPLACEMENT: Chevrolet Truck (Ball Bearing) - With axle shaft removed, expand bearing retaining ring by driving a chisel into it at several points around ring. Support outer face of bearing on Tool J-6378, then press shaft out of bearing and retainer, using an arbor press. Remove outer retainer from shaft. To install, place outer retainer on shaft, then lubricate shaft and bearing and start bearing over shaft. Support inner face of bearing in Tool J-6419-5 and J-6378 in an arbor press and press shaft into bearing until bearing seats firmly against axle shoulder. *NOTE - A pressure of 2700-6000 lbs. is required to install bearing.* Start retaining ring over shaft and press onto shaft against bearing in same manner as bearing was installed. *NOTE - A minimum pressure of 2700 lbs. is required to install retaining ring.*

►*HUDSON & NASH SERVICE REPLACEMENT TORQUE TUBE TRUNNION INSTALLATION: See "Hudson, Nash & Rambler" Rear Axle.*

CONTINUED ON NEXT PAGE

SPICER SEMI-FLOATING HYPOID AXLE

SPICER HYPOID (C nt.)

TORQUE TUBE & PROPELLER SHAFT (HUDSON & NASH): Removal - Raise and support rear end of body. Disconnect hand brake cable at equalizer and remove hand brake bellcrank assembly from torque tube. Disconnect rear stabilizer bar at rear axle tube. Remove truss rods at axle tubes and at center bracket on torque tube. Disconnect torque tube from transmission adapter and move axle assembly and tube to rear to disengage propeller shaft from transmission. Disconnect rear of torque tube from rear axle housing and move tube forward sufficiently to expose coupling. On Hydra-Matic Drive cars, disconnect coupling flange and remove torque tube and propeller shaft. On synchro-mesh transmission cars, the coupling is a slip fit on pinion shaft and a press fit on propeller shaft. On Hydra-Matic Drive cars, remove pinion flange with Puller J-2984.

Installation: Reverse removal procedure, and note the following: Support pinion from rear while pressing companion flange on pinion shaft (Hydra-Matic Drive cars). On synchro-mesh transmission cars, install propeller shaft oil seal and retainer on propeller shaft. Butt propeller shaft at front end against a wood block and drive coupling on shaft with a lead hammer. *(CAUTION* - Do not install the seal and retainer on coupling prior to its installation on propeller shaft). Coupling must be driven on shaft to shoulder on splined area inside coupling. Install spacer, lubricate ground surface on coupling and the torque tube rear oil seal with rear axle lubricant. The propeller shaft with coupling can now be installed on pinion shaft (do not crimp lip of oil seal). Make sure that torque tube seal contacts coupling on the ground surface of coupling.

OVERHAUL

DIFFERENTIAL: Removal - Remove rear axle housing cover and gasket, then remove differential side bearing caps. *NOTE - If bearing caps are not marked for replacement at same location, identify them with punch marks for proper reassembly.* Position Spreader Tool J-5231 (Chevrolet, Hudson, Nash, Rambler, Packard & Studebaker with Model 44 axle); J-5372 (Studebaker with Model 23 & 27 axle); W-129 (Willys), on axle housing, then install dial indicator to indicate amount housing is spread. Expand tool not to exceed .020",then use a pry bar and pry differential assembly out of housing. Remove and tag side bearing cups so they may be reinstalled in original locations. Relieve pressure on spreader tool.

►*POWER-LOCK DIFFERENTIAL DISASSEMBLY NOTE: For disassembly and reassembly procedures see "Power-Lock Differential (Plate Clutch Type)".*

Disassembly (Exc. P wer-L ck Typ Diff rential): Remove differential side bearings with a suitable puller and retain shims located under bearing cones for use at reassembly. Remove ring gear attaching capscrews and tap ring gear off case. Remove differential pinion shaft lock pin (Exc. Model 70 axle), then remove pinion gears, side gears, and thrust washers. On Model 70 axles, remove bolt from differential case cover, then remove cross shaft, pinion gears and thrust washers.

Reassembly (Exc. Model 70 Axle & Power-Lock Type Differential): Install ring gear on case and tighten attaching capscrews to 40-50 ft. lbs. Install thrust washers on side gears and install side gears in bores of differential case. Install thrust washers behind pinion gears and mesh gears with side gears so holes are opposite and in line with each other. Roll gears around until holes are aligned with pinion shaft holes in case, then install pinion shaft and thrust block with lock pin hole in shaft aligned with hole in case. Press shaft into case and measure clearance between side gears and case. This clearance should not exceed .008". *NOTE - On 4-Wheel drive models, side gear clearance on front axles should be .000-.006" with .006" being the absolute maximum.* If necessary, replace thrust washers. Drive lockpin into place and upset end of pin to retain it in case. *NOTE - Do not install side bearings and shims at this time.*

Reassembly (Model 70 Axle): Install ring gear on case and tighten attaching capscrews to 100–110 ft. lbs. *CAUTION – Pull ring gear into position evenly with two or three of the attaching capscrews.* Bend locking tabs over head of screws to prevent loosening in service. Install thrust washers on side gears and install a side gear in each case half. Install thrust washers and pinions on cross shaft, then install the assembly in ring gear side of differential case, meshing side gears and pinion gears. Install differential case cover and side gear assembly on differential case and rotate gears to mesh side gears with pinions. Align cover attaching capscrew holes with holes in case, then install and tighten capscrews securely. *NOTE – Do not install side bearings and shims at this time.*

Installation: With pinion installed and pinion depth and preload adjustment within limits *(See "Pinion Depth Setting" and "Pinion Preload Adjustment" below),* adjust differential side bearing preload and gear backlash *(See "Differential Side Bearing Preload & Gear Backlash Adjustment" below),* then install differential side bearings with proper shim pack under each bearing. Install rear axle housing spreader and spread housing not to exceed .020", then install differential assembly and bearing cups and remove housing spreader. Install bearing caps and tighten bolts to 70-90 ft. lbs. (Chevrolet & Model 70 axle, Hudson, Nash & Rambler); 70-80 ft. lbs. (Studebaker & Packard); 38-42 ft. lbs. (Willys, Exc. Model 70 axle).

PINION & BEARINGS: Removal - Remove companion flange, oil seal, gasket and oil slinger *(See "Pinion Bearing Oil Seal Replacement" above),* then with differential case assembly removed, tap drive pinion and rear bearing cone out of housing with a soft hammer. Tag and save shim pack on splined end of pinion (bearing preload shims) for reference during reassembly. Remove front bearing cone from housing. If pinion bearings are to be replaced, remove rear bearing cup with Tool J-6367 (Chevrolet); W-100 & W-100-4 (Willys). On Hudson, Nash, Rambler, Packard, Studebaker front and rear cups, and Chevrolet and Willys front bearing cups, drive cups from housing with a brass drift and hammer. *NOTE - Tag and save shims from in front of rear bearing cup for use during reass mbly.* Press pinion rear bearing cone off shaft with Tool J-6378 (Chevrolet); J-2245-A (Hudson, Nash & Rambler); J-5365 (Studebaker); W-104 (Willys).

Installation: Install bearing cone on drive pinion using a suitable piece of pipe to seat bearing against shoulder. Install front bearing cup in housing with Tool J-6368 & J-8092 (Chevrolet); J-2534 or J-5367 (Hudson, Nash & Rambler); J-270-6 & J-8092 (Studebaker & Packard); W-142 (Willys). Install correct shim pack in rear bearing recess in housing *(See "Pinion D pth Setting" below),* then install rear bearing cup with Tool J-3234 (Chevrolet); J-2531 (Hudson, Nash, Rambler); J-270-14 & J-8092 (Studebaker & Packard). Install pinion and rear bearing in housing and install outer shim pack *(S e "Pinion Preload Setting" below).* Install outer bearing cone using Tool J-5590 (Chevrolet), J-2204 (Studebaker & Packard). On other models, seat bearing with companion flange, washer and pinion nut. Complete installation of pinion shaft *(See "Pinion Bearing Oil Seal Replacement" above.*

PINION DEPTH SETTING: Procedures are different for the various cars and trucks as indicated below:

Chevrolet: If a new pinion and ring gear are to be installed, note the "plus" or "minus" markings on rear face of original pinion. *NOTE - Pinion markings r present variations from nominal pinion d pth dim nsion.* Approximate depth setting of new pinion may be made by increasing or decreasing shim pack ahead of pinion bearing rear cup to correspond with difference in marking on old and new pinion *(se "Chevrolet Shim Selection Table" below).* To maintain proper pinion bearing preload, shim must be added or subtracted from pinion bearing (front) shim pack to correspond with changes made to rear bearing shim pack. If the difference in markings on old and new pinions is in the plus direction, shims must be added. If in the minus direction, shims must be removed.

Chevrolet Shim S l ction Tabl

Markings on Pinions		Difference Between Markings	Amount To Change Each Shim Pack
New Pinion	Old Pinion		
+8	+5	+3	Decrease. 003"
+5	+8	−3	Increas .003"
−5	−3	−2	Increase .002"
−3	−5	+2	Decrease .002"
+5	−3	+8	Decrease .008"
−4	+2	−6	Increase .006"

CONTINUED ON NEXT PAGE

SPICER HYPOID (C nt.)

Huds n, Nash, Rambl r: *NOTE - Shim pack is determined by amount of shims r m v d at disassembly and by the plus or minus figur tch d on pinion.* For example, if original pinion was marked "+2" and had a shim pack of .035" behind rear bearing cup and the new pinion to to be installed is marked "–1", the shim pack must be increased by .003" to bring new pinion to its correct position. Install pinion bearing front cup *(See "Pinion & Bearing Installation" above),* then install pinion shaft assembly in housing. Check pinion setting as follows: Mount discs J-2499-2 on Arbor Gauge J-6482-1 or discs J-5223-5 on Arbor Gauge J-5223, then install gauge assembly so it is seated firmly in housing bores. Place bearing caps in position and tighten bolts finger tight. Install Gauge Block J-5223-16 in position against end of pinion and clamp in place with Clamp Bar and Screw, J-5223-6 and J-5223-14. Loosen thumbscrew in end of gauge block and move plunger out until head contacts gauge arbor. Lock plunger in position with thumbscrew, being careful not to disturb position of plunger. Loosen screw in clamp holding gauge block against pinion and remove gauge block. Measure distance from end of anvil to top of plunger head with a two-to-three inch micrometer. This measurement represents the distance from rear face of drive pinion to centerline of axle, and should be 2.625" for 1956 models, 2.625" for late 1957 Rambler V8, 2.547" for 1957 Hudson & Nash V8, and 2.095" for 1958 Rambler V8. This measurement applies only to correctly adjusted pinions marked "O". On a pinion marked "+2", the read - ing should be .002" less than this figure and with a pinion marked "–3", the reading should be .003" greater. If micrometer reading shows pinion setting is incorrect by more than .002" plus or minus from given figure, shims equal to that amount must be either added or removed from shim pack between rear bearing cup and housing

Stud baker & Packard: With original shim pack under pinion rear bearing cup, seat cup in housing, then install the shaft and bearing assembly. Lubricate front bearing cone and install on pinion shaft (without preload shims) using Tool J–2204 and companion flange. Tighten nut on tool to obtain 10–20 inch-pounds bearing preload as measured with an accurate spring scale. Use pinion Setting Gauge J–6381 as follows: Install proper size discs on gauge arbor and install discs and arbor in bearing bores of axle housing, then install bearing caps and tighten the capscrews. Place gauge block on pinion, holding it there with the clamp bar and screw. *NOTE – Small extended anvil should extend down along side of pinion gear.* With gauge block in position, loosen thumb screw in end of gauge block and move plunger out of block until plunger head contacts gauge arbor, then lock plunger with thumb screw (use care not to disturb setting). Remove gauge block from pinion, then measure distance from end of anvil to top of plunger head. This measurement represents distance from face of pinion to centerline of rear axle. Measurement on micrometer should be as indicated in table below for a "zero" pinion. If pinions are marked (+) or (–), this must be added or subtracted from the "zero" depth setting. For example: If pinion is marked (+2). .002" must be subtracted from "zero" depth setting. If the pinion is marked (–2), .002" must be added to "zero" depth setting. If pinion depth setting is not correct, shims equalling the difference must be added or remove from shim pack between rear bearing cup and housing to bring setting within limits. Complete installation of pinion (see above).

Studebaker "Zero" Pinion Depth

Spicer Model No.	
44 (All Ratios)	2.625" ± .0015"
23 (Exc. Ratios below)	2.343" ± .0015"
23 (4.1–1, 4.56–1, 4.88–1)	2.250" ± .0015"

Willys: Use Pinion Setting Gauge W–99 which consists of a dial indicator and a mounting fixture to be mounted on rear face of pinion (held in place with "C" clamp which is part of gauge). Before using this gauge, dial indicator must be set to zero through use of a master gauge block supplied with the equipment. Set dial indicator at zero with gauge pin resting on correct lobe of master gauge *(see "Pinion Gauge Setting" table below)* and with one-half turn tension on gauge pin. With pinion installed in axle housing (spacer W–126–6 can be installed on shaft in place of universal joint yoke), and with pinion setting gauge in place, dial reading should be zero for pinions marked "O", or **minus** for pinions marked "–", and should read **plus** for pinions marked "+", by an amount equal to the figure following the "+" or "–" sign on end of pinion. Adjust by adding or removing shims from behind rear bearing cup in housing. Repeat test until correct dial reading is obtained.

Willys Pinion Gauge "Zero" Setting

Spicer Axle Model No.	Lobe of Master Gauge
23	"D"
25 (Exc. 4.27–1 Ratio)	"D"
25 (4.27–1 Ratio)	"G"
44	"E"
53	"F"
70	"G"

► *AXLE MODEL IDENTIFICATION NOTE:* Axle model number will be found on the lower right rib of gear carrier housing when viewed from rear of vehicle.

PINION BEARING PRELOAD: Chevrolet - With original (or adjusted) shim pack behind outer bearing cone and pinion shaft assembly installed in housing (without pinion bearing oil seal and slinger), the torque required to rotate pinion should be 10-20 inch lbs. Add or remove shims behind outer bearing cone to bring preload within limits.

Hudson, Nash & Rambler: Install oil slinger, companion flange and nut (do not install oil seal). Check preload by attaching a spring scale to a "T" handle and socket, and rotate pinion shaft on a horizontal plane. Add or remove shims from between front bearing and shoulder on shaft to obtain a preload of 25-35 inch lbs. required to rotate pinion shaft.

Stud bak r & Packard: With pinion gear set to correct depth, remove front bearing from pinion shaft and install the original pinion bearing adjusting shim pack, then install front bearing and companion flange, using Companion Flange & Pinion Bearing Pusher J-2204 and Holding Tool J-6371. Install flat washer and tighten to 140-180 ft. lbs. Check pinion bearing adjustment with a spring scale hooked to arm of holding tool. The rotating torque should be 10-20 inch lbs. (disregarding starting torque). Install or remove shims from under front bearing as necessary to bring adjustment within specifications.

Willys: To adjust pinion bearing preload, start with approximately .065" shim pack on shoulder of pinion. Reassemble front bearing yoke, washer and nut and tighten nut to 140-180 ft. lbs. (Exc. Model 70 Axle), 225-275 ft. lbs. (Model 70 Axle). Using an inch-pound torque wrench, check rotating torque (disregard starting torque). Torque should be 10-25 inch lbs. Add or remove shims to obtain correct torque.

DIFFERENTIAL SIDE BEARING & GEAR BACKLASH ADJUSTMENT: Hudson, Nash, Rambler - Place differential case assembly in housing and install bearing caps in proper position; tighten capscrews finger tight. Insert two screw drivers between bearing cup and housing on the side opposite the ring and move differential assembly and ring gear away from pinion until opposite bearing cup is seated firmly against housing. Move screw drivers to ring gear side and move assembly over until ring gear teeth contact teeth of pinion. Refer to recording of shim thickness required (taken at time differential case disassembled), and install the shims between bearing cups and housing. Divide total amount of shims between sides in such a manner that all ring gear and pinion backlash is eliminated. Remove bearing caps and take out differential case assembly. Keep each shim pack separate. Remove side bearings from differential and install shim packs on their respective hubs. Install an additional .015" thickness of shims behind the differential bearing on the tooth side of ring gear to provide proper backlash between gear and pinion and proper pre-load. Install bearings. Place axle housing spreader J-5231 in position and spread housing .020" maximum to permit installation of differential assembly. Install bearing caps and use sealing compound on bolt threads. Remove housing spreader and tighten bearing caps to 70-90 ft. lbs. Install dial indicator on housing with contact button resting against edge of ring gear tooth and check backlash between ring gear and pinion which should be .002-.006", and should not vary more than .002" between positions checked; check at four positions on ring gear.

Studebaker & Packard: Place differential case in housing (without shims behind side bearings). Install a dial indicator on housing with contact tip against ring gear back face. Insert two large screw drivers between housing and cup on opposite side from ring gear and move ring gear away from pinion until bearing cone on ring gear side is seated firmly in its cup and against the housing. Set indicator at zero. Move assembly back to-

CONTINUED ON NEXT PAGE

SPICER HYPOID (Cont.)

ward pinion until ring gear meshes lightly with pinion (no backlash or clearance). This reading, less .003" is the thickness of shims required between differential case and side bearing on ring gear side of differential. To find thickness of shims required under other side bearing, subtract the thickness of shims just used from the total side movement obtained earlier (at reassembly of differential). To the figure thus obtained, add 008" shim thickness for pre-load. To facilitate installation of differential assembly in housing, cock the bearing cups and tap them lightly with a lead hammer. When reinstalling bearing caps, be sure numerals on caps and housing correspond. Tighten bearing cap bolts to 70-80 ft. lbs. Mount a dial indicator on axle housing with contact button against one ring gear tooth. Move ring gear by hand to check backlash which should be .003-.006". If backlash is not in the specified range, move shims from one side of carrier to the other to obtain desired setting.

Chevrolet & Willys: With pinion shaft properly installed (depth and preload adjusted), install side bearing cones on differential case (without shims) then install bearing cups matching with cones as marked at disassembly Place differential carrier in housing and install bearing caps tightening bolts just enough to keep caps in place Check ring gear for runout with a dial indicator and correct as necessary Remove indicator then insert a pry bar between bearing and carrier on side opposite the ring gear and move differential case as far as possible toward ring gear side of housing Measure clearance between carrier and bearing on side opposite the ring gear with a long feeler gauge inserted all the way across bearing outer face Record the total gauge thickness, then remove feeler gauge Insert pry bar between carrier and bearing on ring gear side of housing and move differential case toward pinion until no backlash can be detected between ring gear and pinion Measure clearance between carrier and bearing at ring gear side of case with a feeler gauge in same manner as measured at opposite side Record this feeler thickness Remove differential case from housing and remove side bearings Install shim packs as follows *NOTE – If old shims are to be used, make sure nicks in shims caused by bearing puller are placed to line up with notches in case* At ring gear side of case install a shim pack equal to gauge thickness as noted when clearance gauged at ring gear side of case then install bearing tight against shims Subtract the amount of shims installed at ring gear side of case from the feeler gauge measurement taken on side opposite ring gear then add 015" shims to the result of the subtraction to provide bearing preload Install this shim pack on end of case opposite the ring gear and install the bearing tightly against shim pack Install differential case in housing *(see "Differential Installation" above)* Check backlash of gears with a dial indicator If backlash is not in specified range of 003– 006" (Chevrolet) 005– 010" (Willys) interchange shims between the two side bearing shim packs until correct backlash is obtained

POWER-LOCK DIFFERENTIAL (CONE CLUTCH TYPE)

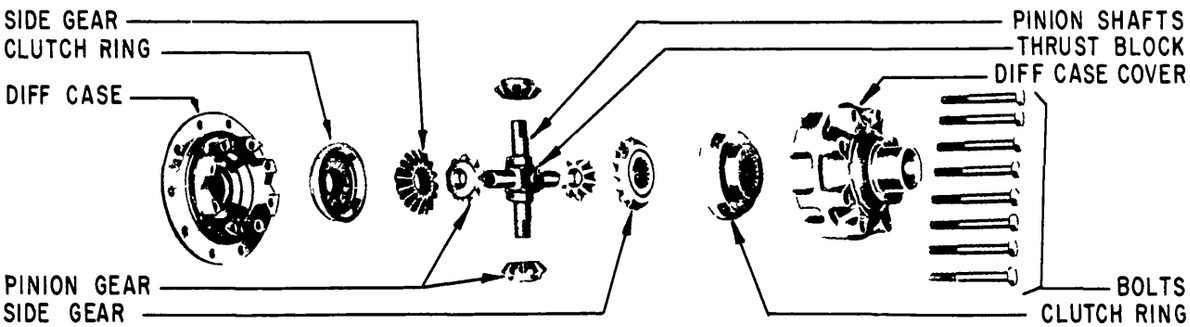
Lincoln & Continental (1957-60)
Packard (1956-Early 1957)
Studebaker (Early 1957)
Willys (1957)

DESCRIPTION: Partial locking type differential. The unit consists of a two-piece case, with each piece having two V-shaped ramps or cam surfaces diametrically opposite. When assembled, the V-shaped ramps of one piece are at a 90° angle to the ramps of the other piece, with the V's facing away from each other. The conventional mounting of pinions is replaced by two individual cross pins with a slidable joint at the center, permitting each one to move independently, although continuously engaged. Ends of the pins are machined in the form of a "V" and ride on the V-shaped ramps. Two internally splined clutch rings are fitted over each of the side gears and mate with tapered surfaces in the case halves. Two internally splined differential gears, as well as the clutch rings, are splined to the axle shaft at each end. Four pinions, carried by the cross pins, mesh with the differential gears. Pinions incorporate shoulders which contact the clutch rings. The unit is interchangeable with the standard Spicer differential.

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model page.*
AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Model page.*
DIFFERENTIAL ASSEMBLY REMOVAL & INSTALLATION: *See "Lincoln, Continental Hypoid" Rear Axle.*

OVERHAUL

►*POWER-LOCK DIFFERENTIAL OVERHAUL NOTE:* Replacement parts are not available for the differential assembly. If parts require replacement due to wear or damage, it will be necessary to install a complete differential unit. The following procedures may be used for inspection or for correcting excessive noise conditions.



►*DIFFERENTIAL ASSEMBLY REPLACEMENT NOTE:* Power-Lock differential assemblies are interchangeable with the conventional assemblies.

DISASSEMBLY: With case assembly on bench (ring gear removed from case), check clearance between cross pins and ramps by manually raising a cross pin up one side of the ramp and inserting feeler gauges. *NOTE – If clearance at this point is less than .045" it is not necessary to disassemble differential case. If clearance is greater than .045", proceed as follows* Remove case capscrews, then remove cover, clutch rings, side gears, cross pins, and pinion gears. *NOTE - Identify each part and place on a clean cloth so that it may be reinstalled in the same relative location.*

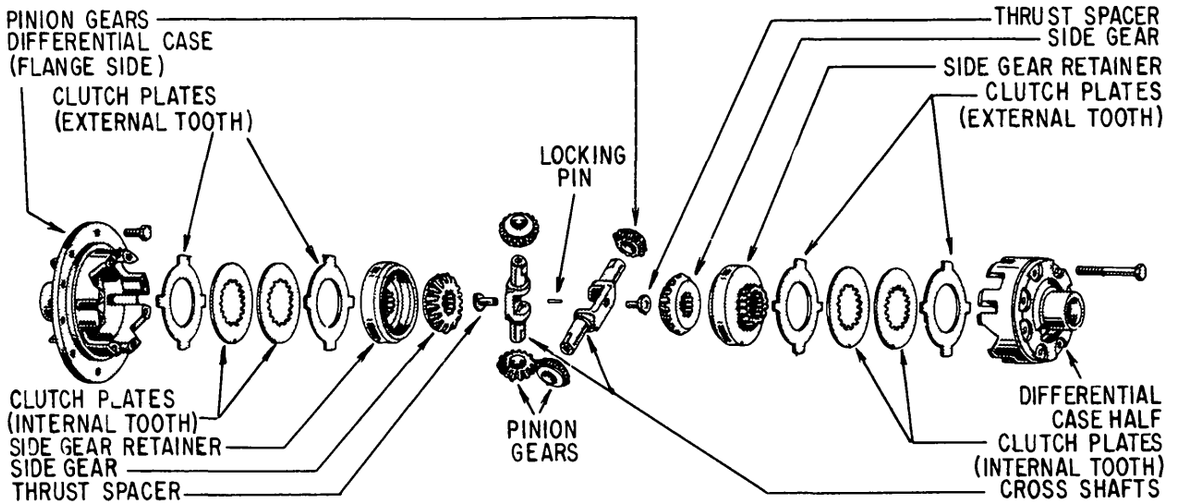
INSPECTION: Clean and inspect all surfaces for scoring burrs, and nicks If excessive, replace complete assembly

REASSEMBLY: Place a side gear with its clutch ring on the bench, then install a 020" shim between side gear and clutch ring and place the pinion gears and cross shaft in proper position on the assembly. *NOTE – Fabricate shims from steel shim stock, of various thicknesses. Shim size should be 2 5/8", O.D., 1½" I.D.* Firmly hold the assembly together and check clearance between shoulder of pinion gear and edge of clutch ring with a feeler gauge. Remove enough shims to allow a minimum backlash of 003" between side gear and clutch ring As it is not possible to directly measure clearance between side gear and clutch ring, determine the thickness of shims required between side gear and clutch ring (in place of the 020" shim pack installed for checking) as follows: As an example, if a .007" clearance was found between shoulder of pinion gear and clutch ring, subtract .007" from thickness of shim pack (.020"), leaving .013" which would be the shim pack required to provide .000" between side gear and clutch ring. As a .003" backlash is desired, decrease the .000" clearance shim pack (.013") by this amount, indicating that a shim pack of 010" between side gear and pinion shaft would provide the desired backlash. Repeat this procedure with side gear and clutch ring on opposite side of case. Apply a light coating of special rear axle lubricant to all parts, then reassemble differential case by reversing disassembly procedures. *NOTE – Match alignment marks stamped on side of differential case assembly.*

LUBRICATION: Use Gear Lubricant, Part No B9L–19A508, only.

POWER LOCK DIFFERENTIAL (CONE CLUTCH TYPE)

POWER-LOCK DIFFERENTIAL (PLATE CLUTCH TYPE)



Buick (1959)
Chevrolet Pass. Car & Corvette (1957-59)
Chevrolet ½-Ton Truck (1959)
Chrysler & Imperial (1959-60)
DeSoto (1958-60)
Dodge (1958-60)
Ford F-100 & F-250 Trucks (1959)①
Oldsmobile (1958-59)
Packard (Late 1957-58)
Plymouth (1958-60)
Pontiac (1958-59)
Rambler V8 (1958-59)②
Studebaker (Late 1957-59)
Willys (1957-59)

① - For Ford Pass Cars, see *"Ford Power Transfer Differential"*
② - For Rambler 6 Cyl, see *"Twin-Grip Differential"*

►CHANGES, CAUTIONS, CORRECTIONS

►*1958-59 BUICK DIFFERENTIAL 'CHATTER' CORRECTION NOTE This method supersedes previous procedures* Raise car off wheels, then remove as much lubricant from rear axle housing as possible, using a suction gun Turn wheels by hand so any oil trapped in case will drain down Use an air pressure type gun having a long nozzle and filled with 10W engine oil, then insert nozzle in filler opening and direct oil at openings in case (at cross pins and ramps) Repeat this for all four openings in case Joggle wheels while flushing to release clutch plates and allow oil to flow through unit Fill housing completely with "10W" engine oil, then start engine and bring it to normal operating temperature with selector lever in "Park" With engine at normal operating temperature, apply brakes and place selector lever in "Drive" range, then **slowly** release brakes and allow rear wheels to rotate 60 to 90 seconds *NOTE - During this period, apply and release brakes gently several times to work plates in unit.* Gently apply brakes to slow rear wheels to a stop, then turn engine off and place selector lever in "Park" *CAUTION - Avoid fast idle or sudden brake application as well as fast selector lever changes to prevent damage to ring gear and pinion* Repeat the suction procedure as outlined above Use a clean suction gun filled with Buick Positive Traction Lubricant, Part No 531536 and spray at least one pint into case openings, then fill housing to proper level with the same lubricant If chatter is not corrected after car has been driven 50 to 100 miles, repeat the procedure If chatter is still not corrected, remove differential case, disassemble and thoroughly clean the unit *NOTE - A slight shudder under heavy acceleration during turns is normal and should not be confused with chatter in differential*

►*1957-59 CHEVROLET POWER-LOCK DIFFERENTIAL OPTIONAL PLATE ARRANGEMENT FOR OFF HIGHWAY OR HEAVY DUTY OPERATION* For maximum traction, assemble plates alternately with an internally splined plate against differential carrier or case *NOTE - This type assembly (maximum traction) will result in tire squeal on turns and a slight tendency to oversteer A slight "clink" (due to necessity for looseness in assembly to allow complete release) is normal*

POWER LOCK DIFFERENTIAL ASSEMBLY (PLATE CLUTCH TYPE)

►*1958 CHRYSLER, DESOTO, DODGE, PLYMOUTH POWER-LOCK DIFFERENTIAL LOOSE CASE BOLT CORRECTION* This condition may be noticed by a loud knocking noise in area of rear axle assembly and may be caused by differential case bolts striking carrier housing To correct, remove differential assembly from axle assembly and service as necessary Tighten differential case bolts to 45 ft lbs, then tack weld bolt heads to differential case using electric welding equipment and a very small weld *CAUTION - Do not tack-weld with case assembled in carrier* Later case bolts have left hand threads and will not loosen in service

DESCRIPTION This assembly replaces conventional differential assembly and consists of a multiple disc type clutch (4 or 5 plates) located between each side gear and differential housing The external tooth plates are driven by the differential housing and the internal tooth plates are splined to each side gear retainer Pinion gears are mounted on cross shafts which are free to move on ramps of differential housing *NOTE - Some models have axle thrust spacers that extend on both sides of cross shaft and are held in place with a locking pin*

OPERATION As engine power is transmitted from ring gear to differential case the driving force causes ends of cross shafts to move up ramps of cam surfaces and apply a load on the disc clutch This action locks the axle shafts in normal straight ahead driving preventing momentary spinning of wheels when leaving the road or when encountering poor traction The division of the torque between axle shafts varies in accordance with traction of each rear wheel When cornering the faster turning outer wheel relieves the load from clutch surfaces so that wear is reduced to a minimum and the action is essentially that of a conventional rear axle

REAR AXLE ASSEMBLY REMOVAL *See "Rear Axle" on Car Model pages*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Model pages*

DIFFERENTIAL ASSEMBLY REMOVAL & INSTALLATION *See conventional rear axle service procedures*

►*STUDEBAKER DIFFERENTIAL OVERHAUL NOTE* Three different model axle assemblies are used Identification and special service procedures are as follows

Model "23" (No Identification on Housing) – These assemblies have 45° ramps and the clutch assemblies consist of two plates with external lugs and two plates with internal teeth on each side of differential When installing clutch pack start with an external lug plate against side gear retainer ring then alternate with an internal tooth plate an external lug plate then with an internal tooth plate

Model "44" (Stamped With a "T" on Metal Tag) – These assemblies have 30° ramps and the clutch assemblies consist of two plates with external lugs and two plates with internal teeth When installing clutch pack install the two internal tooth plates between the two external lug plates

Model "44" (Stamped With "45" on Metal Tag) – These assemblies have 45° ramps and the clutch assemblies consist of either four or five plates on each side of differential Assembling the clutch pack is the same for both types Start with an external lug plate then alternately install an internal tooth plate and an external lug plate until required number of plates are installed

►*POWER-LOCK DIFFERENTIAL OVERHAUL NOTE· Removal of ring gear and differential side bearings is not required unless replacement is necessary*

DISASSEMBLY: With differential removed from rear axle housing check clearance between pinion shafts and "V" ramp of differential case as indicated below *(see "Adjustment")*, then check to see that differential assembly halves are marked (punch marks number or letter) for use at reassembly *NOTE - If halves are not marked, scribe a line across both halves* Mark ends of pinion shafts case and differential gears with paint so these parts will be installed at the same location Remove end housing attaching bolts and remove end housing Remove side gear retainer ring and clutch pack from end housing then remove cross shaft and pinion gear assembly side gear retainer ring and clutch pack from flange side of differential housing Note the relation of clutch plates for use at reassembly

CONTINUED ON NEXT PAGE

POWER-LOCK DIFFERENTIAL (PLATE CLUTCH TYPE) C nt.

INSPECTION: Clean all parts in solvent and dry with air. Check for worn, cracked, or distorted clutch plates. Check all other parts for nicks, burrs, and abnormal wear.

►*DIFFERENTIAL REASSEMBLY NOTE: If cross shaft-to-"V" ramp clearance is not correct as noted at disassembly, see "adjustment" below for procedures required to obtain a correct clearance before reassembling differential.*

REASSEMBLY: Oil clutch plates thoroughly with special Power-Lock lubricant *(see "Lubrication" below)*, then proceed as follows: On all models except Chevrolet Pass. Cars and Studebaker models with Model "23" axle, install internal tooth and external lug clutch plates alternately on side gear retainer ring beginning with an external lug plate (4 or 5 plates required, depending on model). *NOTE – On Chrysler, DeSoto, Dodge, and Plymouth, the 1/16" thick clutch plate must be installed so it will be against differential case.* On Chevrolet Pass. Cars and Studebaker models with Model "23" axle, install an external lug plate on retainer ring, then install **two** internal tooth plates, completing the clutch pack with an external lug plate. Install clutch pack on the other retainer ring in the same manner. *CAUTION – Install only the same number of clutch plates as originally installed, and in the same order.* Install proper clutch pack and retainer in flange half of differential case, then install side gear, pinion gears, and cross shafts. *NOTE – On models with axle shaft thrust spacers, assemble cross shafts, pressing thrust spacers on thrust pin until spacers contact each other, then install cross shafts and pinion* gears. Install other side gear, retainer ring and clutch pack, aligning the external lugs with slots in differential case. Check location of alignment marks on both halves of case, then place end housing over clutch pack, engaging slots with external lugs of plates. Check to make sure all alignment marks are in proper alignment, then install housing attaching bolts and tighten to 35-45 ft. lbs. (45-65 ft. lbs. on Chev. Trucks).

CHECKING & ADJUSTING: With differential completely assembled, check and adjust clearance between pinion shafts and "V" ramp of differential case as indicated below for various models.

Checking Cross Shaft-to-"V" Ramp Clearance (Exc. 1959 Chevrolet Pass. Cars & Ford Truck Models): Insert feeler gauge under one side of "V" ramp on one end of pinion shaft, and the diagonally opposite side of "V" ramp on other end of pinion shaft. *NOTE - This will rotate the pinion shaft up the ramp in either a clockwise or counterclockwise direction.* Progressively increase thickness of feeler gauge under both ends of shaft equally until no clearance remains (clutch pack is closed). Check both pinion shafts in this manner. The clearance under pinion shafts should be within limits indicated in table. If not correct, adjust thickness of clutch plates or replace parts as recommended for the individual car models (below).

Checking Cross Shaft-t -"V" Ramp Cl arance (1959 Ch vrol t Pass. Cars & F rd Truck Mod ls): Insert feeler gauges under b th sid s of the "V" on both nds of pinion shaft at the **same time.** *NOTE - This requires four feeler gauges at four positions.* Increase thickness of all four gauges equally until no clearance remains (clutch pack is closed). Check both pinion shafts in this manner. The clearance should be within limits as indicated in table. If not correct adjust thickness of clutch plates or replace parts as recommended for individual car models (below).

Car Model	Clearance
Buick (1959)	① .030" Max.
Chevrolet Pass. Cars (1957-58)	.010-.035"
Chevrolet Pass. Cars (1959)	.005-. 015"
Chevrolet Trucks (1959)	② .001-.035"
Chrysler, DeSoto, Dodge, Plymouth(1958-60)	.020" Max.
Ford Trucks (1959)	.005-.015"
Oldsmobile (1957-58)	② .002-.020"
Oldsmobile (1959)	.010" Max.
Pontiac (1958-59)	② .002-.020"
Packard (1957-58)	② .020" Max.
Rambler (1958-59)	.004-.030"
Studebaker (1957-59)	③ .020" Max.
Willys (1957-59)	④

① – .005" maximum difference in clearance between the two pinion shafts.
② – .002" maximum difference in clearance between the two pinion shafts.
③ – .002" (30° ramp), .005" (45° ramp) maximum difference in clearance between the two pinion shafts.
④ - Clearance should be only a few thousandths of an inch and it should be equal at all four cross shaft ends.

Adjusting Clutch Pack (Cross Shaft-to-"V" Ramp Clearance): Recommended procedures for the various car models are as follows:
Buick – If pinion shaft clearance is greater than .030", replace excessively worn parts to bring clearance within limits. If the two cross shaft to ramp clearances are not within .005" of each other, equalize the clearances by disassembling differential and equalizing the total thickness of each clutch pack. Special thick service clutch plates, Part No. 1191503 & 1191504, or special thin plates, Part No. 1191501, and standard production plates, Part No. 531308 should be substituted as required to bring clearance within specifications. *NOTE – Production plates average .095" thickness. Special thick plates are marked .096" and special thin plates are marked .094".*

Chevrolet Pass. Cars - If pinion clearance is not within limits *(see table above)*, disassemble differential and inspect all parts for wear. Replace any parts that are worn or defective. If the two cross shaft to ramp clearances are not within approximately .002" of each other, equalize the two clutch pack thicknesses by interchanging plates and discs between the two packs, and/or installing thicker clutch plates, Part No. 531403 (.096-.101" thick), as necessary to bring clearances within limits. *NOTE - If n cessary, install n w compl t clutch packs on each sid of differential.*

►*CHEVROLET CLUTCH PACK & CLEARANCE NOTE: Changing the clutch pack thickness .002" (1957-58); .0065" (1959), will change pinion shaft-to-ramp clearance by .003" (1957-58); .005" (1959). If clutch pack thickness is increased, pinion-to-ramp clearance will be decreased.*

Chevrolet Truck – If the difference between one pair of pinion shaft measurements and the other pair is greater than .005", disassemble and measure all clutch plates and discs with a micrometer. Change thicker parts to side opposite to bring difference in clearance to .005" or less. If clearance at either of the pinion shafts is greater than .035", and it cannot be decreased by interchanging discs and plates from one side to the other, replace with service clutch plates to obtain correct clearance. Service clutch plates are available in the following thicknesses: .096–.101", .092–.097", .088–.093", .058–.063".

Chrysler, DeSoto, Dodge, Plymouth – If cross shaft-to-"V" ramp clearance exceeds .020", install new clutch plates in each clutch pack.

Ford Trucks – If pinion shaft-to-"V" ramp clearances exceed .015", install new clutch plates and discs which are available in one thickness only. If clearance is excessive after installation of new plates and discs, other parts which affect clearance and show wear must be changed.

Oldsmobile – If clearance between pinion shaft and "V" ramp is greater than .010", install thicker clutch plates to bring clearance within limits. Refer to chart (below) to determine thickness to be added to clutch plates to bring pinion shaft-to-ramp clearance to .002". As an example: if .019" feeler gauge (at either end of one cross shaft) was required to take up the clearance, .012" thickness should be added to total clutch plate thickness. Clutch plates are available in the following thicknesses: .092–.097" (Part No. 531402), .096–.101" (Part No. 531403), .088–.093" (Part No. 531404), .058–.063" (Part No. 531405).

OLDSMOBILE CLUTCH PACK ADJUSTING CHART

Cross Shaft Clearance Measured at Ramp (Step 3)	Approximate Thickness to be Added to Clutch Plates (To Obtain .002" Cross Shaft Clearance at Ramp)
.011"	.006"
.012"	.007"
.013" to .014"	.008"
.015"	.009"
.016"	.010"
.017" to .018"	.011"
.019"	.012"
.020" to .021"	.013"
.022"	.014"
.023" to .024"	.015"
.025"	.016"

CONTINUED ON NEXT PAGE

POWER-LOCK DIFFERENTIAL (PLATE CLUTCH TYPE) C nt.

Packard - Same as for Studebaker (below).

P ntiac – If pinion shaft-to-"V" ramp clearances are not within the range of .002–.020" or if clearances between the two shafts differ more than .002", interchange clutch plates from one side to the other, or install the necessary thicker clutch plates to bring clearances within proper limits. Clutch plates are furnished in the following thicknesses: .096–.101", .092–.097", .088–.093". .058–.063".

Rambl r – Replace clutch plate assemblies.

Stud bak r (M d ls Id ntified by a "T" Stamped on M tal Tag n Housing) – *NOTE – These models have differential assemblies with 30° ramps. See "Studebaker Diff rential Ov rhaul Note" above.* If pinion shaft-to-"V" ramp clearances exceed .020" or are not within .002" of each other, interchange plates from one side of differential to the other and/or install new plates as necessary to bring clearances within limits. *NOTE – Clearance at pinion shaft is affected .003" for .002" vertical rise in total plate stack height.*

Studebaker (Models Identified by "45" Stamped on Metal Tag on Housing): – *NOTE – These models have differential assemblies with 45° ramps. See "Studebaker Differential Overhaul Note" above.* If pinion shaft-to-"V" ramp clearances exceed .020" or are not within .005" of each other, install new clutch plates.

NOTE – Plates in these clutch packs are not of variable thickness.

Willys - If backlash at axle is not within limits *(see "Willys Backlash Check" below)*, replace clutch pack as necessary.

WILLYS BACKLASH CHECK: Raise one rear wheel, then with transmission in gear, measure travel of the raised wheel on a 10" radius from wheel center. Total movement should not exceed 1¼" for a new axle. Make sure axle assembly universal joint yoke does not move during the check.

LUBRICATION: Only the following special lubricants are to be used in "Power-Lock (Plate Clutch Type)" Differentials.
Buick: Part No. 531536.
Chevrolet Pass. Cars & Trucks: Part No. 3758790 or 3758791.
Chrysler, DeSoto, Dodge, Plymouth: Part No. 1879414.
Ford Trucks: Part No. B9A–19580–A.
Oldsmobile: Part No. 531536.
Pontiac: Part No. 531536.
Rambler: Part No. 3201017.
Studebaker: Part No. SP–50136.
Willys: Part No. 94557.

② - For Ford Pass. Cars, *s e "Edsel & Ford Equa-Lock Diff rential".*
③ - For Rambler 6 Cyl. Cars, *see "Twin-Grip Differential".*

►CHANGES, CAUTIONS, CORRECTIONS

►*1960 BUICK DIFFERENTIAL "CHATTER" CORRECTION: NOTE - This m thod supersedes previous procedur s.* Raise car off wheels, then remove as much lubricant from rear axle housing as possible, using a suction gun. Turn wheels by hand so any oil trapped in case will drain down. Use an air pressure type gun having a long nozzle and filled with 10W engine oil, then insert nozzle in filler opening and direct oil at openings in case (at cross pins and ramps). Repeat this for all four openings in case. Joggle wheels while flushing to release clutch plates and allow oil to flow through unit. Fill housing completely with "10W" engine oil, then start engine and bring it to normal operating temperature with selector lever in "Park". With engine at normal operating temperature, apply brakes and place selector lever in "Drive" range, then **slowly** release brakes and allow rear wheels to rotate 60 to 90 seconds. *NOTE - During this period, apply and release brakes g ntly several times to work plates in unit.* Gently apply brakes to slow rear wheels to a stop, then turn engine off and place selector lever in "Park". *CAUTION - Avoid fast idle or sudden brake appli) tion as well as fast selector lever changes to preven damage to ring gear and pinion.* Repeat the suction procedure as outlined above. Use a clean suction gun filled with Buick Positive Traction Lubricant, Part No. 531536 and spray at least one pint into case openings, then fill housing to proper level with the same lubricant.

POWER-LOCK DIFFERENTIAL (BELLEVILLE PLATE TYPE)

If chatter is not corrected after car has been driven 50 to 100 miles, repeat the procedure. If chatter is still not corrected, remove differential case, disassemble and thoroughly clean the unit. *NOTE - A slight shudder under heavy acceleration during turns is normal and should not be confused with chatter in differential.*

►*WILLYS STANDARD FRONT & REAR AXLE CONVERSION TO POWER-LOCK TYPE NOTE:* Standard type front and rear Spicer model assemblies can be converted to Power-Lock type by installing the proper differential assembly as follows:
Model 44 Assembly - All vehicles with Model 44 axle can be converted if the original axle shafts have involute splines. If shafts do not have involute splines it will be necessary to install two new shafts to make the conversion.
Model 23, 25, 27 & 70 Assemblies - On these models it is necessary only to install the proper Power-Lock Differential assembly.
Model 53 Assembly - This model cannot be converted except by installing a complete axle assembly.

►*1960 CHEVROLET POWER-LOCK DIFFERENTIAL PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* Later production cars have a new differential assembly consisting of five plate (two friction discs, two friction plates, and one "Belleville" plate), replacing the former four plate type unit. *The "Fiv Plate" clutch pack cannot be used to replace th "Four Plate" type because of dimensional differences in differential case.*

►*1957-60 CHEVROLET POWER-LOCK DIFFERENTIAL ("FOUR PLATE" TYPE) OPTIONAL PLATE ARRANGEMENT FOR OFF HIGHWAY OR HEAVY DUTY OPERATION:* The normal arrangement of clutch plates as used in production is with the "Belleville" type plate installed next to differential case and with the two internally splined plates placed together next to "Belleville" plate. The other externally tanged plate is placed next to side gear retainer. For maximum traction, the plates can be rearranged with an internally splined plate placed next to differential case, followed by the "Belleville" type plate, an internally splined plate, and finally, the externally tanged plate next to side gear retainer. *NOTE - The maximum traction clutch pack arrang m nt will caus tire squeal on turns and a tendency to ov rst r.*

DESCRIPTION: Basic design is the same as used on 1959 models. The addition of "Belleville" type plates in

CONTINUED ON NEXT PAGE

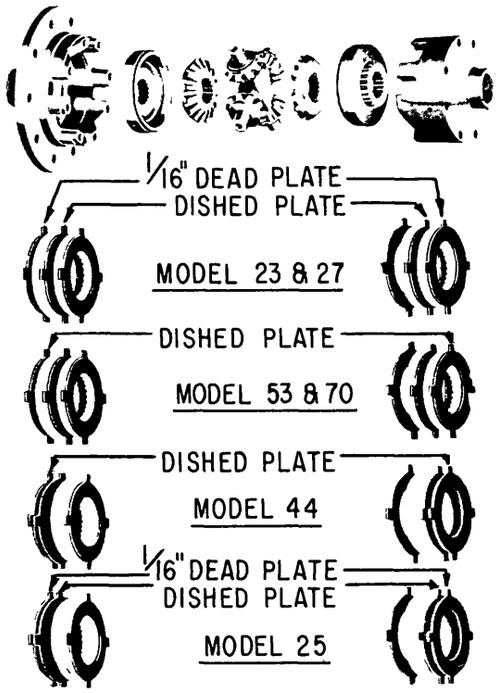
POWER-LOCK DIFFERENTIAL (BELLEVILLE PLATE TYPE) Cont.

differential clutch pack has changed the checking and adjusting procedures as indicated in "Overhaul" below.

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Model pages.*

DIFFERENTIAL ASSEMBLY REMOVAL & INSTALLATION: *See conventional rear axle service procedures.*



OVERHAUL: *See "Power-Lock Differential (Plate Clutch Type)" in this section and note the following:*

Buick: The outboard clutch plate of each clutch pack is a "Belleville" type spring and should be installed in the same direction (plate is coned) as originally installed. Pinion shaft-to-differential case ramp clearance has been eliminated with the use of "Belleville" type clutch plate in each clutch pack. If clearance exists, replace clutch plates with special thicker service clutch plates.

Chevrolet (Early Cars): These units are the same as used in 1959 with the exception that the inner tanged friction plate in each clutch pack has been replaced with a "Belleville" type (dished) plate. A repair kit is available which includes two of the new dished type plates for service installation on 1958-59 and early 1960 Pass. Cars and ½-Ton Trucks. There is no clearance between pinion shaft and "V" ramp on units with dished type plates. A clearance at this point indicates wear of component parts.

Chevrolet (Later Cars): This is a new type unit with three tanged friction plates installed in clutch pack alternately with two internally splined friction plates. The tanged friction plate placed next to differential case is .059-.061" thick. All of the other plates are .094-.096" thick including the "Belleville" type plate (tanged) which is installed between the two internally splined plates. *NOTE - "Belleville" type plate is installed with concave side toward differential case.* There should be no clearance between pinion shaft and "V" ramp. A clearance at this point indicates wear of component parts.

Oldsmobile: A "Belleville" (Dished) type clutch plate is used in each clutch pack, replacing the first plate in case and first plate in cover. Concave side of "dished" plate should face the clutch pack when installed, allowing the inside diameter to contact case of cover. 1960 clutch plates are .094" thick and the need for selective fitting of plates is eliminated. Checking ramp clearance is not required as the "Belleville" plates preload the clutch pack and eliminate clearance between ramp and cross shaft.

1960 WILLYS DIFFERENTIAL CLUTCH PACKS

Pontiac: The outboard clutch plate of each clutch pack is a "Belleville" type spring and should be installed in the same direction (plate is coned) as originally installed. Pinion shaft-to-differential case ramp clearance should not exceed .004" maximum at either side (zero ramp clearance preferred). If clutch pack parts are to be replaced, obtain a combination to give a total thickness of .475" in each clutch pack. Clutch plates are available in thicknesses of .094" and .096".

►*1959 PONTIAC CLUTCH PACK REPLACEMENT NOTE:* If one or more of the friction discs or clutch plates need replacing, the entire clutch pack should be replaced on each side. Use two kits, Part No. 535595, each of which contains two friction discs, two clutch plates, and one "Belleville" spring type plate.

Rambler: Clearance between pinion shaft and differential case ramps must not exceed .010". If clearance exceeds .010", replace both clutch packs.

Studebaker: *NOTE - There are three different clutch pack combinations using "Belleville" type plates as follows:*
Model 27 Axle (45 Type) - Two clutch plates (externally tanged) and two clutch discs (internally splined) are used. The outer clutch plate (tanged) in each clutch pack is a "Belleville" type plate which must be installed with "Dished" side toward clutch pack.
Model 27 Axle (45B Type) - Same as Model 27 (Type 45) axle except that an additional wear plate is installed between outer clutch disc (internally splined) and differential case at each side.
Model 44 Axle (45B Type) - Three clutch plates (externally tanged) and two clutch discs (internally splined) are used. The outer clutch plate in each pack is a "Belleville" type which must be installed with "dished" side toward the clutch pack.

►**Studebaker Note:** Pinion mate shafts may be tight on their ramps. Clearance between shaft and ramp should not exceed .010" and should be equal at all cross shaft ends. If one or more clutch plates, discs, or wear plates require replacement, the entire clutch pack should be replaced.

Willys: *NOTE - There are four different clutch pack combinations using "Belleville" type plates as indicated in illustration.* Install friction plates in the order shown in illustration. "Dished" plates in the clutch pack are always installed with convex side toward the case. Each pinion mate shaft can be tight against its ramp, or in the event there is a clearance between shaft and ramp, clearance should only be a few thousandths and it should be equal at all four cross shaft ends.

4-WHEEL DRIVE FRONT AXLES

1959-60 FORD TRUCKS

Ford F-100 & F-250 Truck (1959-60)

DESCRIPTION: Spicer Model 44-4F. Full-floating, hypoid gear type with Spicer "Cross Type" axle shaft universal joints. Differential assembly is similar to rear axle used on F-250 & F-350 Series trucks.

AXLE RATIOS: *See Car Model pages.*

AXLE SHAFT REMOVAL: *See Car Model pages.*

AXLE HOUSING ASSEMBLY REMOVAL: *See Car Model pages.*

OVERHAUL & ADJUSTMENT: *See "Ford Truck Hypoid".*

1957-59 CHEVROLET TRUCKS

Chevrolet ½, ¾ & 1-Ton Trucks (1957-59)

DESCRIPTION: Full-floating, hypoid gear type assembly of own design. Constant velocity type universal joints are provided at each wheel to deliver full power at any turning angle. Front and rear axle assemblies are the same on each truck model.

AXLE RATIO: *See Car Model pages.*

AXLE SHAFT REMOVAL & WHEEL BEARING ADJUSTMENT: *See Car Model pages.*

OVERHAUL & ADJUSTMENT: ½-Ton Models - *See "1955-60 Chevrolet Hypoid".*
¾ & 1-Ton Models - *See "Chevrolet Truck Hypoid Full Floating".*

1960 CHEVROLET TRUCKS

Chevrolet ½ & ¾-Ton Trucks (1960)

DESCRIPTION: Spicer Model 44-5F. Full-floating, hypoid type with "yoke & trunnion" universal joint at each front wheel.

AXLE RATIO: *See Car Model pages.*

AXLE SHAFT REMOVAL & WHEEL BEARING ADJUSTMENT: *See Car Model pages.*

OVERHAUL & ADJUSTMENT: *See "1954-60 Spicer Hypoid".*

ℂ - On L6-226 4-Whl Drive models with 4 27-1 axle ratio, use Gauge Block "G"

EATON POSITRACTION DIFFERENTIAL

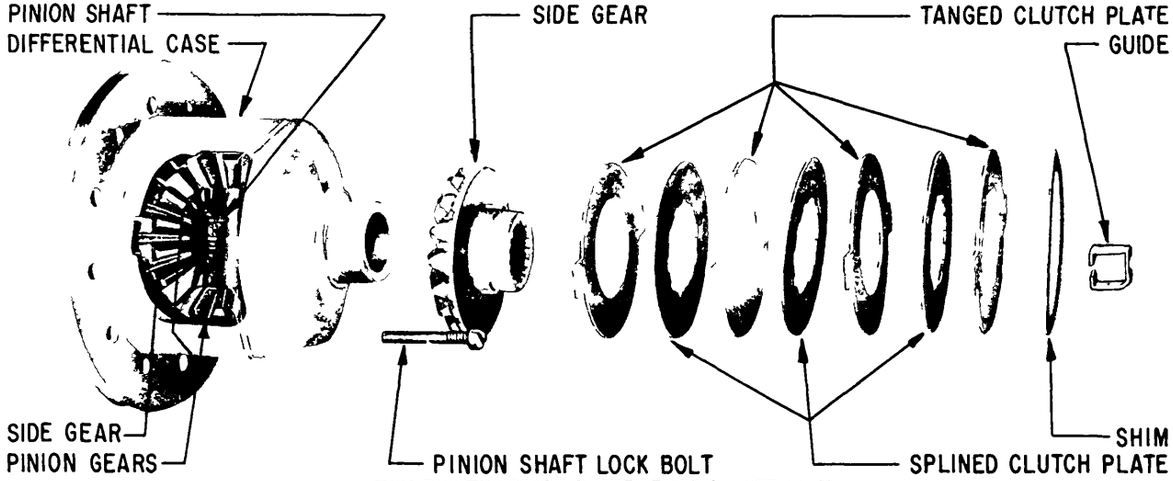
Ch vrolet ½-T n Truck (1960)

►*OPERATING NOTE:* Under operating conditions where one rear wheel is on excessively slippery surface and the other wheel is on a good traction surface it may be necessary to slightly apply the parking brake (three or four notches) to produce enough resistance to the spinning wheel to energize differential clutch plates. It is suggested that a very slow application of the throttle on starting be used to provide maximum traction by preventing "break away" of the non-slipping wheel.

DESCRIPTION: This unit which is designed to replace the conventional differential assembly in a standard rear axle housing consists of disc clutches between side gear and case at each side of differential. These clutches are engaged by the tendency of differential pinion gears to force side gears outward as drive is transmitted through the system. The clutch pack on each side of differential consists of seven plates, four of which are driven by the differential case through two tangs spaced 180° apart. The other three discs are splined directly to differential side gear hub.

REMOVAL & INSTALLATION: Same as for conventional differential assembly. *See "Chevrolet Hypoid" in 1956 Annual Data or later Manual edition.*

Disassembly: Remove pinion shaft lock screw and remove shaft from case, then rotate pinion to openings in case and remove pinion gears. Remove side gears, clutch discs, shims and guides (one side at a time) noting location of discs shims and guides to aid in reassembly.



Inspection: Clean and dry all parts, then check all gears for chipped or worn teeth. Check spherical seat of pinion gears and mating seats in case. Inspect case for wear or damage. Check fit of differential pinion gears on shaft. Replace all parts if excessively worn. *NOTE - G ars must b replaced in s ts.* Inspect clutch discs and side gears for excessive wear or scoring. Replace parts as necessary.

Reassembly: 1) Apply a coating of lubricant to all clutch discs and stack four eared discs and three splined discs alternately on each side gear. Place the same shims that were removed (or equivalent thickness), on outside eared disc of each clutch stack.

2) Adjust pinion gear-to-side gear backlash as follows: Install one side gear, with shims and clutch disc, in case and install pinion gears and pinion shaft. Compress clutch stack by inserting a screwdriver or other wedge between side gear and pinion shaft. Install a dial indicator with contact button against a pinion gear tooth and check the backlash. If backlash is greater than .006", add a shim between clutch disc and case. If backlash is less than .001" decrease shim thickness. *NOTE - A .002" shim increase will decrease backlash approximately .001".* When correct backlash is obtained, remove side gear with clutch discs and shims, keeping parts together for final assembly. Repeat same procedures with other side gear and discs to determine shim thickness required for .001-.006" backlash.

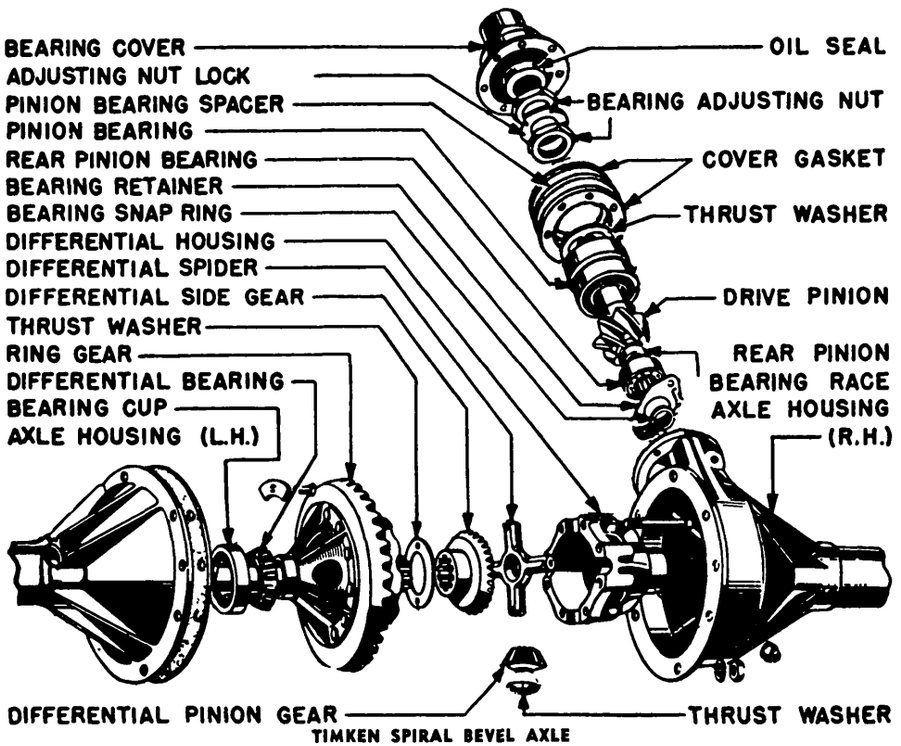
3) Apply lubricant to guides and place one guide over ears at each side of each clutch stack so chamfered corner of guides face away from side gear. Install one side gear with guides, discs and shims, then position case so side gear stays in place and install side gear, guides, discs and shims in other side of case. Install pinions, pinion shaft and lockscrew but do not tighten screw.

4) Check the assembly by inserting an axle shaft in one side of differential and rotating to make sure differential action is satisfactory.

EATON POSITRACTION DIFFERENTIAL ASSEMBLY

TIMKEN SEMI-FLOATING

TIMKEN MODEL NO. 51540



Willys, Truck, Model 475-4WD (1954-55) ①
Willys, Truck, Model 6-226-4WD (1954-56) ①

①–This axle used optionally with "Spicer Semi-Floating (Model 53-2)" Rear Axle since August, 1951.

DESCRIPTION: Spiral bevel, semi-floating type with Hotchkiss Drive. Axle housing is "split" type with one differential side bearing cup seated in recess in each half. Pinion is mounted on taper roller bearings in housing integral with right hand axle housing. Pinion bearing assembly is special type with a single outer race (bearing cup) for both roller bearings. Axle shafts are mounted on single taper roller bearing at each wheel, each bearing taking thrust in one direction while the thrust in the opposite direction is transmitted to the opposite bearing through the axle shafts.

AXLE SHAFT REMOVAL & WHEEL BEARING ADJUSTMENT: Same as for other Willys models. See Spicer Hypoid Semi-floating axle for complete data.

REAR AXLE DISASSEMBLY & REASSEMBLY: Remove eleven screws holding axle housing halves together, slide left housing half away (axle shaft will pull out of differential gear splines). Lift out differential assembly (pull out toward left so that right axle shaft is disengaged from differential gear splines). To remove side bearings, use Puller Tool No. W-104-20 to remove roller and cone assemblies from differential case shoulders, Tool W-200 to pull bearing cups from axle housing. To remove pinion assembly, take out bolts in housing holding bearing retainer (spacer) and cover, lift off cover and oil seal assembly, bearing retainer, and gaskets. Assemble Puller W-203 on end of pinion shaft, pull pinion and bearing assembly out toward front. See Pinion Assembly data below for disassembly of this unit.

TIMKEN SPIRAL BEVEL AXLE

Pinion Bearing Assembly: To dismantle this assembly, clamp pinion in vise (use brass jaws), bend up lips on locking washer, remove pinion locking nut, washer, and adjusting nut. Lift off front bearing cone and roller assembly, (slip fit on shaft), and bearing cup. Use Puller No. W-104-32 to remove rear bearing cone and rollers. To remove pinion bearing from housing, drive out two brass rivets in retaining plate from front of housing, remove plate, drive bearing out using a brass drift. To reassemble, install pilot bearing retainer, drive pilot bearing in place using Tool W-207, press pilot bearing inner cup on end of pinion shaft and install lockring (NOTE–New pinions furnished with cup and snap ring installed). Press rear pinion bearing cone and roller assembly firmly against pinion using Tool W-205, install bearing cup and front bearing cone and rollers, install washer, adjusting nut, locking washer, and locknut. Adjust pinion bearing pre-load (see below), securely tighten locknut and bend locking washer lip against nut. Install pinion assembly in housing using Installer Tool W-203. (CAUTION–Make certain pinion shaft enters pilot bearing in housing.) Check oil seal in pinion shaft cover (install new seal, if required, with Tool W-199). Install bearing retainer and cover assembly on housing using new gaskets (CAUTION–Align oil drain hole with opening in housing), install retainer bolts and tighten securely.

Pinion Bearing Pre-load Adjustment: With pinion bearings assembled on pinion shaft, tighten adjusting nut to pre-load bearings so that torque required to turn pinion shaft is 12-18 in. lbs. Locknut must be tight when checking this pre-load.

Pinion Setting: Pinion position is not adjustable. Ring gear and pinion are furnished only in matched sets and ring-and-pinion gear mesh will be satisfactory if axle correctly assembled and backlash is within limits of .004-.008".

Differential Assembly: To dismantle assembly for replacement of parts, cut lockwire, remove nine screws, separate differential case halves. Replace Differential Pinions, Pinion Thrustwashers, Side Gears, and Gear Thrustwashers as **matched sets.**
CAUTION–Use of mixed new and old parts will result in premature failure. Make certain that differential case screws are secured with lockwire when reassembling. Use Tool W-206 to install side bearing cone and roller assemblies on case, Tool W-204 to install bearing cups in housing. Before reassembling axle, examine ring gear thrust plate for wear and replace if necessary (plate is riveted in left hand housing)

Ring & Pinion Gear Backlash: .004-.018". Check backlash after axle completely reassembled.

1954-55 BUICK HYPOID

All Series (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►**REAR AXLE LEAKAGE CAUTION:** Oil leaks may occur at front pinion bearing unless following precautions observed:

Oil Leakage into Propeller Shaft (causing shaft unbalance)—Can be prevented by properly sealing pinion shaft when propeller shaft installed. *See Pinion & Propeller Shaft Assembly below.*

Oil Leakage into Torque Tube (and transmission)—Can be corrected by installing special oil seal in front of pinion front bearing. *See Pinion Bearing Oil Seal Installation below.*

Oil Leakage at Torque Tube & Housing Mounting Flange—Correct by disconnecting torque tube and installing new gasket (gasket is made of special material—DO NOT use any substitutes for this gasket).

►*CAUTION*—Do not remove torque tube from carrier housing for any other reason than gasket replacement to correct oil leakage. These parts are matched and aligned during manufacture and are not furnished separately.

►*REAR AXLE BREATHER PRODUCTION CHANGE:* A breather has been installed on the rear axle housing to eliminate the possibility of leakage. The new breather, Part No. 3700490 can be installed on axles not so equipped as follows: Remove left axle shaft, and ring gear. Drill a .359-.369" diameter hole on top of the housing approximately 14" from center line of carrier and drive breather into place *CAUTION*—Place a greased rag in axle housing to prevent any chips entering. Make sure that axle is clean of all foreign material before reassembling ring gear and axle shaft.

►*1955 RING GEAR & DIFFERENTIAL CASE PRODUCTION CHANGE:* Farly type is riveted to differential case. Later type is bolted to case, using 12 special 3/8"-24, 300M bolts *(CAUTION—These bolts should not be replaced with any other kind under any circumstances).* The special bolts are identified by six straight lines around bolt head center and in some cases a manufacturers trade mark may also be in center of head. If the bolted type ring gear used to replace early riveted type, the differential case must also be replaced. *DO NOT rework the old case for use with the new ring gear.*

►*1955 DOUBLE ROW RADIAL THRUST BALL BEARING INSTALLATION ON EARLIER MODEL CAUTION:* The new oil seal, Part No. 1339437 must be used to avoid interference with nut hex when bearing, Part No. 954919 is used.

►*1955 REAR AXLE HOUSING FILLER PLUG BREAKING CORRECTION:* Plugs will break if over-torqued. Tighten plug to 20-30 ft. lbs.

►*1955 REAR AXLE CARRIER PRODUCTION CHANGE:* Carrier bolting flange has been increased in thickness from .620" to .800", and reinforcing ribs have been extended to the outer circumference of the bolting flange. Carrier attaching bolts (to rear axle housing) have been eliminated and studs, pressed into housing, have been substituted.

►*1955 PINION GEAR PRODUCTION CHANGE:* A tapered gear (tapered on back of pinion) replaces the early type. A new spacer also entered production at the same time to compensate for changes in pinion.

►*1955 PINION GEAR INSTALLATION IN CARRIER CAUTION:* Different pinion bearing spacer tools are required for early and late type (tapered) pinion installation. *See "Pinion & Propeller Shaft Installation" below.*

►*1955 PINION BEARING REPLACEMENT CAUTION:* If 1955 bearing arrangement (one rear roller bearing) is to be installed in a rear axle in which the old arrangement (double rear roller bearing) has previously been run, *a new gear set MUST be used.* The ridge formed between the two radial bearings would cause rapid wear of the new single bearing.

DESCRIPTION: Hypoid gear, semi-floating type with torque tube drive. The pinion is supported in carrier by two Hyatt roller bearings (rear) and a double-row radial-thrust ball bearing (front) on 1952-54 models, by one roller bearing (rear) and a double-row radial-thrust ball bearing (front) on 1955 models.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REPLACEMENT: Raise rear of car and place on stands. Clean rear end of chassis and all parts surrounding axle housing. Remove wheel and brake drum, drain rear axle housing and remove cover. Remove side pinion shaft lock screw and push pinion shaft from differential case, and remove spacers and pinions. Push axle shaft inward and drive the horseshoe shaped washer from grooved inner end of axle shaft, using tool J-1515. Support axle shaft while pulling it out of axle housing to avoid damaging bearing oil seals. *CAUTION—Do not allow axle to rest on oil seals during repairs.*

Axle Shaft Endplay: Controlled by spacer block between axle ends in differential case. Endplay should be .000" to .008" maximum. Replacement spacers are furnished standard size, and in two oversizes, each spacer having two dimensions for selective fitting. Install spacer between axle shafts and with both shafts pulled out as far as possible, check clearance between axle and spacer. If clearance exceeds .008", turn spacer ¼ turn and test clearance again. If unable to adjust endplay to .008", replace spacer with an oversize, or install new bronze thrust washers between side gears and differential case.

Wheel Bearing & Seal Replacement: After removal of axle shaft, disconnect link from shock absorber arm. Disconnect brake pipe from wheel cylinder and plug openings. Remove entire brake assembly from axle, supporting brake out of way to prevent damage to brake cable. Remove outer seal and roller bearing, then remove inner oil seal, using Remover J-1436 (sliding hammer & puller). If inner bearing race on axle shaft is to be replaced, grind part way through race and split it off shaft. Press a new bearing race into place against shoulder on shaft. Drive a new inner seal squarely and lightly into axle housing using care to avoid distorting seal. Install bearing into housing by tapping with a light drift on alternate sides of bearing *(CAUTION—Do not tap on rollers).* Install new seal and complete installation by reversing removal procedure.

PROPELLER SHAFT & FRONT BEARING: Propeller shaft is part of pinion & shaft assembly. *See "Overhaul" below.*

►*TORQUE TUBE CAUTION: Torque tube and carrier flanges are matched and aligned at the factory and should not be disturbed except for installation of a new gasket (to prevent leakage) or for replacement of either of the two parts.*

OVERHAUL: *After removal of axle shafts, differential side bearings and thrust washers, proceed as indicated below:*

►*1953-54 PINION & PROPELLER SHAFT REMOVAL:* With the type seal used in these cars, it is possible to remove and replace pinion and propeller shaft without disconnecting from torque ball. CAUTION—Care must be taken when installing the propeller shaft with the axle in the car to start propeller shaft in through seal gently to avoid striking seal retainer, as damage will result. Press propeller shaft and pinion assembly into carrier, as driving it in can cause damage to front bearing.

►*PINION PRESS, TOOL J-1292-E, REWORK (Supersedes Rework of Yoke Screws J-1292-36):* To use new type yokes, J-1292-40 and J-1292-41 which are wider than yokes previously furnished with press, it will be necessary to rework the press as follows: Remove the shoulders at each end of propeller shaft support (adjacent to tool side rails) so that surfaces of support between the support slot and the side rails are parallel to top of side rails. Weld casting to side rails and a point below support slot, both at front and rear of the support. *Do not weld upper surface of support at junction with side rails.* It is suggested that if Yoke Screws J-1296-36 were previously reworked, that new screws be secured. New yokes and screws are available in Conversion Kit J-1292-43.

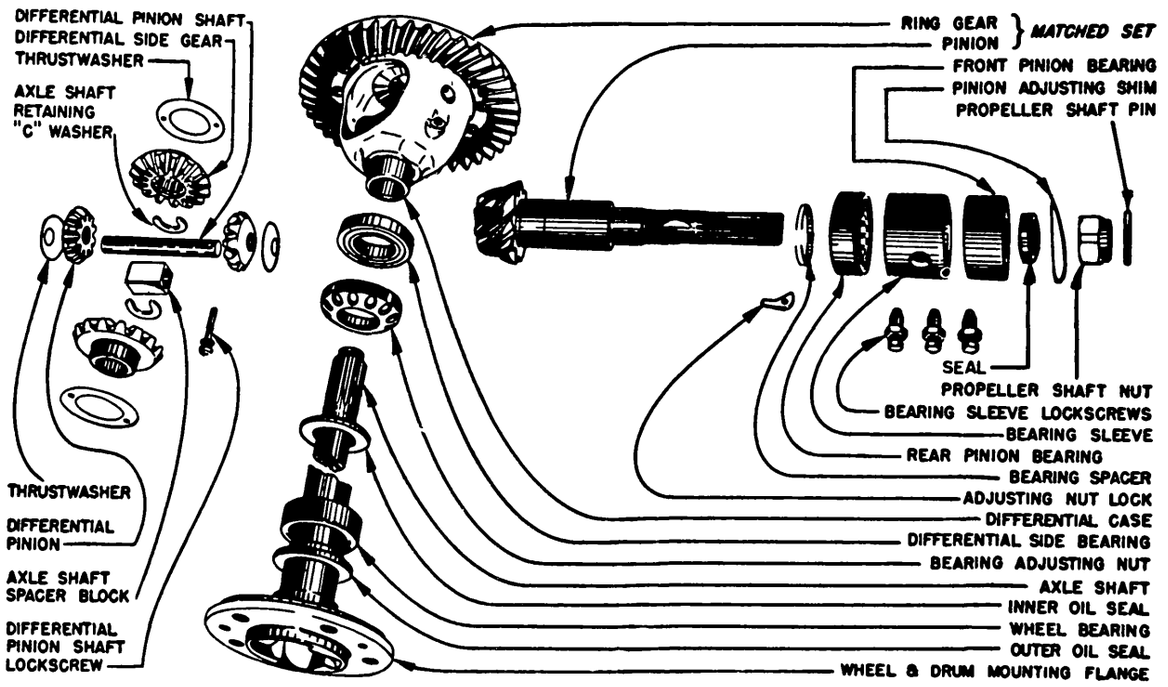
Disassembly: *(NOTE—Before removing differential assembly, check the gear lash with a dial indicator. See "Differential Case, Ring Gear, & Bearing Installation" below).* After removal of both axle shafts, remove differential side gears and thrust washers from case. Mark differential bearing caps so they can be reinstalled in original positions on carrier. Mark both differential bearing adjusters for location, then remove locks and check the bearing adjustment *(See "Reassembly" below).* Remove ring gear and case assembly from carrier, keeping each bearing race with its original bearing.

Pinion & Propeller Shaft Removal & Disassembly—*(NOTE*—Before removing pinion and shaft, the pinion shaft wear can be determined by mounting a dial indicator, with 1¼" extension, to bear vertically against drill center in pinion gear. Pry up on pinion gear with a bar a number of times and check indicator reading. Reading should be less than .0015". If greater, the bearing is worn and should be replaced). Loosen locknuts and remove three bearing sleeve screws from housing. Pull pinion and shaft assembly, using Pinion Shaft Puller J-5502. Remove all pinion bearing shims from propeller shaft and carrier housing to prevent loss or damage. Mark pinion and propeller shaft so that

CONTINUED ON NEXT PAGE

1954-55 BUICK HYPOID (C nt.)

parts can be reassembled in the same relative position. File or cut off end of propeller shaft coupling pin and drive out pin, then pull propeller shaft from pinion using Press J-1292-C. Drive up staked section of pinion bearing lock nut and remove nut, gripping pinion shaft on splined end in vise. *Do not grip pinion gear in vise even though soft jaws are used.* Press off pinion front bearing using Bearing Remover Plates J-5737-6 installed in Press Plate Holder J-358-1 with recessed side upward. *NOTE*-The double row ball bearing will have a slight drag when installed on pinion due to being preloaded.



Differential Case, Ring Gear, & Bearings-*(NOTE-Early type ring gear is riveted to case. Later type is bolted. See Production Change above).* Remove all bolts from ring gear (if bolted type) and separated gear from case. If necessary to replace early (riveted type ring gear) type ring gear, drill ½" hole into rivets using a ¼" drill **on ring gear side,** drive out rivets with a punch inserted in drilled hole. Check gear mounting face for burrs around bolt holes and remove burrs with a mill file. Mount case in differential carrier with a dial indicator set to check runout of machined flange surface. If runout exceeds .002", flange must be trued up. To remove differential bearings, pull bearings from case using Puller J-2241 (the ends of puller fit into notches in differential case so that pressure can be applied to bearing inner race). DO NOT PULL ON ROLLERS.

R assembly: *NOTE-Propeller shaft & pinion gear assembly must be checked for runout whenever pinion and shaft installed regardless of whether new or old parts used.*

►*1955 RING GEAR & DIFFERENTIAL CASE PRODUCTION CHANGES: See Production Change above for installation of later type assembly in earlier models.*

Differential Case, Ring Gear, & Bearings-Check matching numbers on new ring gear and pinion (if being used). Bolt gear to differential case (if later bolter bolted type) using 12 special 3/8"-24, 300M bolts, Part No. 186627 *(these bolts are identified by six radial lines around bolt center).* Install bolts **without lockwashers** and tighten bolts on opposite sides of case to 25-30 ft. lbs., then tighten in same manner to 50-60 ft. lbs. On early type (riveted ring gear), use Riveting Jig J-2196-A to install rivets. Use correct rivets which allow 5/16" shank length for heading. Install rivets from ring gear side and use 8 ton pressure to head rivets cold. Install rivets in diametrically opposite positions until all rivets are installed. Recheck gear runout after all rivets installed. Examine bearing seat on differential case for burrs or scores and remove all high metal with a mill file. Coat bearing seat with engine oil or white lead and install bearing using Replacer J-2242, which is designed to pilot in the case and bear squarely against bearing inner race. Press bearing into position (do not hammer it in).

►**Pini n R ar R ll r B aring N t :** Clearance between bearing rollers and pinion shaft should be .0005" (desired), .0014" (maximum allowable). Check bearings for wear by measuring thickness of roller and outer race at four or five points around bearing(use micrometer and make certain that bearing is absolutely clean). Micrometer reading should be .6756" min., .676" max. Replace bearing if less than .6756".

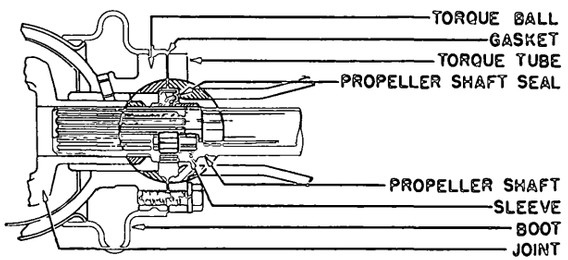
BUICK HYPOID DIFFERENTIAL & PINION GEAR ASSY. (TYPICAL)

Pinion & Propeller Shaft Reassembly - Install parts on shaft in following order. Rear bearing spacer, two rear bearings (1954), one rear bearing (1955), bearing lock sleeve, with chamfered end toward spline (1954), with the thin edge toward the roller bearing (1955). Press front bearing solidly against shoulder of pinion shaft using tube of proper size to bear against inner race only (1952-54), using Bearing Replacer Plate J-5737-7 in Plate Holder J-358-1 (1955). *CAUTION - DO NOT hammer bearing into place as brinelling will result.* Make sure that outer surface of bearing locknut is clean and free of nicks or burrs, then install a new bearing oil seal with spring loaded edge pointed away from hex on nut. Install locknut on pinion with seal toward ball bearing. While gripping splined end of pinion in vise (with soft jaws), tighten nut to a minimum of 150 ft. lbs. Stake outer edge of locknut down into notch in pinion and push oil seal flat to facilitate assembly, then press pinion into propeller shaft until coupling pin holes are aligned using Press J-1292-C and correct yokes. Make sure that pinion is a tight fit in propeller shaft. Install a new coupling pin and solidly rivet both ends. *CAUTION - Whenever a pinion and propeller shaft are assembled together, the compl te ass mbly must be checked for straightness. See "Checking & Straightening (using V-blocks)" b low.*

►**Pinion Sealing Note:** Splined joint must be sealed to prevent lubricant entering propeller shaft and causing unbalanced condition. Seal shaft by dipping end in Presstite Sealer(Permatex or white lead may be used), before assembling propeller shaft. Pinion shaft must not be a loose fit in propeller shaft.

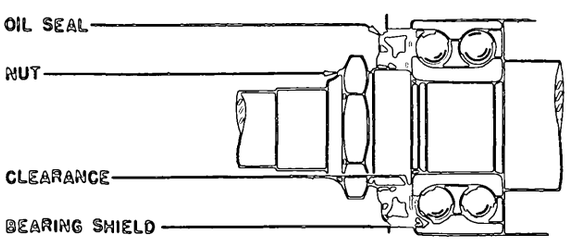
Checking & Straightening (Using V-blocks)-Support pinion and shaft assembly on V-blocks at each end (forward block just to rear of splines at forward end of shaft, rear block under pinion rear roller bearing race). Use dial indicator to measure run-out at points 3" in from each end of shaft tube *(CAUTION*-do not allow unevenness of tube surface to cause indicator to bounce indicating wrong reading). If run-out not within .005" at these two points, straighten tube by exerting pressure on center of tube (support tube at same point at front end and under bearing lock sleeve at rear for straightening). Then check run-out at center of shaft tube. If run-out exceeds .010" at this point, straighten tube while supporting it on blocks at tube weld point at each end. Then check run-out at pinion front ball bearing. If run-out exceeds .001", support shaft at forward V-block and at bearing lock sleeve at rear end, exert pressure at weld points on rear end of tube. Recheck all run-out points, then check run-out at extreme forward end of shaft (must be less than .002").

►*CAUTION: Mor than .002" run-out at forward nd of shaft will cause rapid wear of universal joint bushing and leakage of transmission oil into rear axle.*



CONTINUED ON NEXT PAGE

1954-55 BUICK HYPOID (Cont.)



Pinion & Propeller Shaft Installation-*(CAUTION-Two different Pinion Shaft & Gear Assemblies used. These assemblies require use of different spacer tools for correct installation of the pinions. See "Production Changes" above).* Before installation of pinion and propeller shaft assembly make sure that all parts are clean and dry and that bearing shims are not crimped or buckled. Place the original number and thickness of pinion bearing shims over propeller shaft and against front bearing. Use rear axle lubricant to thoroughly lubricate bearings and coat outer surface of oil seal to aid installation. Lightly coat shims to hold them in place. As pinion and propeller shaft assembly is inserted into carrier, turn propeller shaft to engage splined front end in universal joint *(CAUTION-Be very careful to start shaft through front seal in torque tube without damaging the seal retainer. If axle assembly is under car, the universal joint yoke will guide propeller shaft so that sleeve will enter seal centrally. If axle is not under car, a second man should guide shaft as sleeve enters seal. As pinion bearing enters carrier, place tool (See "Pinion Bearing Spacer Tool Note" below)* between bearing and pinion gear. These spacer tools allow bearing to be pushed into place without binding. Mount Replacer J-55-2 on carrier and press shaft and pinion forward until shims and front bearing are firmly seated. Align holes in pinion bearing lock sleeve with tapered holes in carrier and install three sleeve lock screws. Tighten each lock screw a little at a time until lock sleeve is solidly seated and screws are uniformly tightened to 35-40 ft. lbs. Tighten the locknuts to 15-20 ft. lbs. (1954), 12-15 ft. lbs. (1955). *CAUTION - Excessive tightening of locknuts will cause lock screws to withdraw sufficiently to allow end play of pinion bearing. Remove spacer tool.*

▷Pinion Bearing Spacer Tool Note: Consists of a horseshoe shaped spacer which should be inserted between pinion and rear bearing when tapping on face of pinion to seat bearings in carrier (use bronze driving block on pinion and remove tool after installation completed). Spacer Tool No. J-5499 (1954 with late type pinion gear) J-5909 (1955 first type pinion), J-5973 (1955 with second type "tapered" pinion).

Differential Case, Ring Gear & Bearing Installation-Mount ring gear and case assembly in carrier with a dial indicator set to check runout of gear. Runout should not exceed .003". Correct as necessary. Place outer races on differential bearings but do not oil bearings as this would interfere with bearing adjustment. Install gear and case assembly and slide bearing adjusters into position so that threads are properly engaged in threads in carrier pedestal. Install bearing caps with bolts, *(CAUTION-Make sure that caps are installed in original p sition marked before removal).* Turn bearing adjusters to engage threads. Tighten cap bolts to 20 ft. lbs., and then back off bolts ¼ turn. Using Adjuster Wrench J-1365-A turn adjusters as required to set ring gear lash at approximately .010" with both adjusters in contacts with bearings. *(CAUTION-Do not use punch and hammer to turn adjusters as this will distort adjusters and a pr per bearing adjustment cannot be made).* Back off one adjuster (preferably the left) while observing bearing rollers and outer race, until rollers and race just stop turning, then tighten adjuster 4 to 5 notches to properly seat bearings and adjusters. Slowly back off adjuster until bearing outer race just stops turning. Recheck for this "free position" at least once to make sure of proper position. From "free position", tighten adjusting nut 2½-3 (1952-Early 1953 with First type housing and carrier), 2-3 (Late 1953 & later with Later housing and carrier) notches to preload the bearings, then tighten all four cap bolts to 100-120 ft. lbs. Mount a dial indicator to bear against a ring gear tooth so that contact can be made near heel end of tooth. Check gear backlash. On a new gear set, the lash should not be less than .006" nor more than .011", with .007-.009" preferred. If original gear set is being installed, the original gear backlash should be maintained. If backlash is not within limits, move ring gear to right or left as required to secure proper backlash. To move ring gear, loosen all four bearing cap bolts ¼ turn; loosen one notch on bearing adjuster on side toward which gear is to be moved and tighten one notch on opposite side. *(CAUTION-When* one adjuster is loosened, always tighten opposite adjuster the same amount in order to maintain the bearing preload adjustment). One notch change of both adjusters in the same direction will result in changing gear lash approximately .0035". Always tighten all bearing caps to 100-120 ft. lbs. after adjusters have been moved and recheck lash with dial indicator. When lash is properly set, install both bearing adjuster locks. Install differential side gears and thrust washers in case, lubricate bearings and install axle shafts.

PROPELLER SHAFT SPLINE SEAL

PINION SHAFT OIL SEAL

Pinion Setting (Using J-5647 Gauge): This pinion setting gauge consists of a "master gauge" and an "indicator gauge" upon which Dial Indicator KMO-5647 is mounted. Make certain that gauge parts are clean, particularly the center and discs on indicator gauge and the centering holes, indicator pads and the disc pads on the master gauge. Install the small contact button on stem of dial indicator and mount dial indicator on indicator gauge of tool. Place the indicator gauge on master gauge so that spring loaded center is engaged in centering hole corresponding to the indicator pad "B" (which is used for any of the following gear ratios stamped on pinion: 43-11, 43-12, 41-12, 42-13. *NOTE-Pad "A" is used for certain previous models.* Center the indicator contact button on specified indicator contact button on specified indicator pad and lock indicator by tightening lock screw. Hold yoke down firmly, with both discs contacting the horizontal and vertical pads on master gauge, and set dial indicator at "zero". Place transmission in "neutral". Make certain that differential bearing seats in carrier are clean and free of burrs, and that center in pinion is also clean. Rotate pinion until blank tooth between the matching numbers and the pinion setting mark is slightly counterclockwise of top center (at 11 o'clock). This tooth is called the gauging tooth (used for locating and gauging during production) and should be used for gauging. Place indicator gauge in carrier with discs seated in bearing seats (clear of threads and inner edges), with gauge center engaged in center of pinion, and with contact button having good contact on gauging tooth of pinion. Press gauge yoke firmly inward toward pinion and read dial indicator noting whether it is plus (+) or minus (-), as indicated by arrows on surface of yoke. Recheck indicator zero setting on master gauge to make sure it was not changed in handling. If the old ring and pinion gear set is being reinstalled and it had been in use long enough to establish a wear pattern on teeth, the original setting found at time of removal should be maintained. If the ring gear and pinion set is new or has not been in use long enough to establish a wear pattern on teeth, the dial indicator reading should be within .001" of pinion setting marked on pinion.

Pinion Adjustment: Remove pinion and propeller shaft assembly and remove all pinion bearing shims from shaft or from carrier housing. Wipe shims dry, and measure the total thickness with a micrometer. Increase or decrease total thickness of shims to obtain proper pinion setting, by using a different combination of shims *(NOTE-These* shims are furnished in thickness ranging from .010' to .019' in increments in .001"). As an example, if pinion is marked + 8, but dial indicator reads +6, decrease total thickness of shims by .002" (if the above marking and dial reading were "minus", shims would be increased in thickness). If dial reading were to read +10 for the above marked pinion, increase total thickness of shims by .002". Install pinion and propeller shaft assembly with a new combination of shims and be sure to tighten the three bearing sleeve locks uniformly to 35-40 ft. lbs., and lock nuts to 15-20 ft. lbs. Check pinion setting with gauge. Setting must be within .001" of setting marked on pinion.

Form 50 B

1956-60 BUICK HYPOID

All Series (1956-60)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1956 REAR WHEEL BEARING OIL LEAKAGE CORRECTION & PRODUCTION CHANGE:* An "O" ring seal, Part No. 1466050 is being used in later production cars and can be used on early cars to correct oil leakage. The new seal is installed in groove on outer diameter of the rear wheel bearing.

▷*1956 SERIES 70 DIFFERENTIAL OIL PUMP ELIMINATED:* The oil pump is no longer used in production and whenever the rear axle assembly is disassembled, the oil pump should be removed.

▷*1957 DRIVE LINE RATTLE CORRECTION:* A rubber "square cut" ring, Part No. 1181614 can be installed between the rear propeller shaft and universal joint at the bearing location. Install ring over splines and against face of rear coupling on front propeller shaft. Coat splines with type "O" grease, then reassemble front and rear propeller shaft assemblies and drive lock pin in place. *NOTE* - Force may be required to compress ring which can be done by inserting a small drift or punch as a lever to line up the holes.

▷*1957 REAR AXLE OIL LEVEL CAUTION:* To prevent over-filling of rear axle, the fluid level should be from 1/4 to 3/8" below bottom of filler plug opening.

▷*1957 REAR PROPELLER SHAFT REWORK TO PREVENT LOSS OF LUBRICANT FROM SPLINED COUPLING (Early Production Cars):* Drill a 1/16" diameter hole in plug located at bottom of spline coupling and another hole in propeller shaft tube. These holes act as vents to prevent pressure build-up which will force grease out. Remove the seal retainer and install an .029" thick steel washer, Part No. 5672246 (Saginaw shafts), No. 1179324 (Spicer shafts). *(NOTE* - Saginaw shafts can be identified by the "convex" plug at bottom of spline coupling. Spicer shafts have a "concave" plug at this location. As further identification, the seal retainer on the Saginaw shaft is "staked" around its entire diameter. On Spicer shafts, it is "staked" only in four positions). Before installing seal, washer, and retainer, use a sealing compound on both sealing face and coupling. On Saginaw shafts, stake retainer all the way around. On Spicer shafts, stake the retainer in four places.

▷*1957-58 U-JOINT NON-INTERCHANGEABILITY CAUTION:* 1957 and 1958 U-Joints must not be interchanged (use of incorrect type would result in drive line roughness and vibration) and joints can be identified as follows: 1957 Type - Marked by two notches in line with rear yoke of joint. 1958 Type - Not marked but rear yoke has omitted spline at two points (180° apart) which are 45° off centerline of yoke.

▷*1958 & LATER UNIVERSAL JOINT INSTALLATION CAUTION:* Rear joint has an omitted spline at two points which are 45° off centerline of yoke. Do not use incorrect universal joint. When installing this type universal joint, the two omitted splines must be aligned with blind splines on propeller shaft to provide correct relationship of front and rear universals and prevent drive line vibration.

▷*1958-60 REAR PROPELLER SHAFT LUBRICATION NOTE:* Lubricate propeller shaft coupling and splines (when assembling) with type "O" (non-fibrous) chassis lubricant and pack cavity beyond spline about 2/3 full of grease. *CAUTION - DO NOT plug vent hole in propeller shaft welch plug when servicing as excess lubricant will accumulate in torque tube ahead of access hole. Limit power grease gun to one shot.*

▷*LATE 1958 & 1959 REAR AXLE HOUSING REPLACEMENT CAUTION:* The side gear baffles have been eliminated in 1959 models and in some late 1958 models. When overhauling late 1958 models, determine if case contains baffles, If it contains baffles, baffles must be used when differential is assembled. If it does not contain baffles, the baffles must not be installed. If it is necessary to install a 1958 case (with baffles) in a 1959 model, the baffles must be installed.

DESCRIPTION: Hypoid gear, semi-floating type with torque tube drive. The pinion shaft and gear are supported in carrier by two tapered roller bearings. 1957 and later propeller shafts are two-piece types having two universal joints. The rear universal joint is welded to front end of rear propeller shaft and is supported in torque tube by a sealed ball bearing.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REPLACEMENT: Place car on stands under rear axle housing with wheels clear of floor. Remove rear wheel and brake drum. Remove nuts holding wheel bearing retainer plate to brake backing plate, leaving bolts in place to support backing plate. Pull axle assembly using Puller J-6176 with a slide hammer. Be careful not to disturb backing plate. Replace two opposite nuts finger tight to hold backing plate in position. To install axle (if wheel bearing or seal are the only new parts used), reverse removal procedure and install the old wheel bearing retainer gaskets with same number and thickness of new gaskets. If new rear axle housing or new brake backing plate are used, install axle shaft and bearing assembly without retainer gaskets. Using slide hammer and Puller J-6176, drive axle shaft and bearing into place until bearing is fully seated. To hold retainer plate snug against face of the bearing, install four nuts finger tight. With backing plate pushed tight against housing flange, measure clearance between retainer and backing plate with feelers (use two feelers at same time at opposite sides of retainer and average the two readings so obtained and select the number of new gaskets as required to give .005-.020" less thickness than average of the two measurements). Replace nuts holding wheel bearing retainer plate to brake backing plate and tighten to 65-75 ft. lbs. Then check with a .001" feeler gauge under retainer plate between two lower bolts. If gap exists, remove plate and apply non-hardening Permatex on both sides of gasket to prevent leakage. Replace brake drum.

Wheel Bearing & Seal Replacement: After removal of axle shaft, nick the wheel bearing retainer ring (the ring need not be completely split, but nicked deep enough in 3 or 4 places to spread it). Retaining ring will then slip off with light pressure. Press wheel bearing off using Plate J-6191 in a press. If seal only is defective, pry old seal out of bearing and install new seal using Guide J-6213. Push seal in carefully with fingers until lip is over bearing inner race; then remove installing guide and drive seal in flush with a flat wood block. Press bearing and seal assembly against shoulder on shaft using Installer J-6257 in a press *(CAUTION - Bearing retainer must be on shaft before bearing is installed).* Press retainer ring against bearing with chamfer toward bearing.

OVERHAUL

DISASSEMBLY: 1) Remove rear axle assembly from car and place on suitable stands. Disconnect torque tube brake line from tee fitting located on axle housing. Disconnect strut rods from torque tube bracket. Fasten the two struts to each other loosely, keeping all parts in their original positions. On 1956 models, remove torque tube to carrier bolts and slide torque tube and propeller shaft from carrier. On 1957-60 models, remove the front torque tube to rear torque tube bolts and nuts. Slide front torque tube and propeller shaft assembly from rear torque tube. If any part of propeller shaft assembly needs repair, drive spring pin out and separate front and rear propeller shafts. *CAUTION - The strut rods are easily bent when disconnected.*

2) Remove brake line from housing and both axle shaft assemblies, *see "Axle Shaft Replacement" above.* On 1956 models, remove carrier to axle housing nuts. On 1957-60 models, rotate axle housing so carrier is upward, then remove rear torque tube to carrier bolts and remove rear torque tube. On all models, remove carrier housing nuts and lift carrier from housing.

3) Place carrier assembly in a suitable mounting fixture. Check existing gear lash with a dial indicator positioned against tooth of ring gear (this will indicate gear or bearing wear and will also enable used gears to be installed at original lash setting to avoid changing of gear tooth contact). On 1956 Series 70 with an oil pump, remove oil lines and pump. On all models, remove differential bearing pedestal bolts and open pedestals by tapping a wedge in each pedestal slot. *CAUTION - DO NOT use excessive force on wedges.*

4) On 1956 models, remove differential bearing supports using Puller J-6199 and slide hammer. *See J-6199 Tool Modification above.* On 1957-60 models, remove differential bearing supports using Puller J-6553 with either a sleeve and screw puller or a sleeve and hydraulic ram screw On all models, install Spreader J-6185 and tighten spreader bolt just enough to free case assembly. *CAUTION - Do not spread pedestals more than is necessary to free case.* Lift case straight out until side bearings are half-way clear of pedestals, then take hold of bearings with both hands to keep them from falling and lift case assembly out. *CAUTION - Keep right and left bearings, shims and supports in a set so that they may be reinstalled in the same order.* Remove spreader tool. Mark ring gear and case so they may be reinstalled in same position. Remove ring gear.

5) Drive pinion shaft pin from pinion shaft and then drive shaft from case. Remove pinion shaft shield from case. Mark side gears, pinions and washers so they may be reinstalled on same side. Remove side gears, pinions and washers.

CONTINUED ON NEXT PAGE

1956-60 BUICK HYPOID (C nt.)

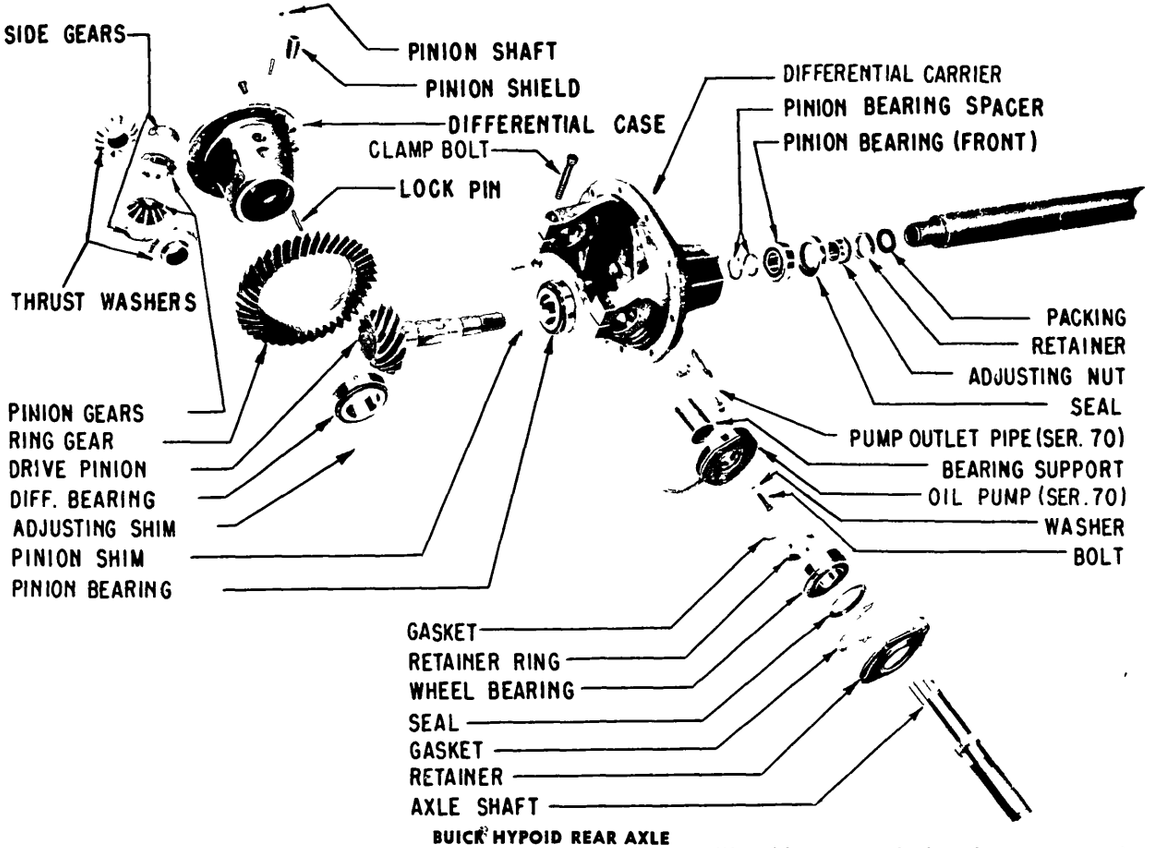
6) If differential bearing is to be replaced, pull bearing outer race from case using Differential Bearing Remover J-6552. Check pinion bearing pre-load (see "Pinion Bearing Pre-load Adjustment" below). It is also advisable to check pinion depth setting (see "Pinion Depth Setting" below).

7) Cut out and drive up staked section of pinion bearing locknut with a cape chisel, being careful not to damage threads on pinion. Hold pinion nut to carrier with Holder J-6245 and turn pinion clockwise through nut using socket J-6192 and Handle J-6246. As pinion nut is removed, hold hand under pinion to catch it, as it may fall through.

8) If rear bearing is to be replaced or pinion depth setting is to be changed, remove rear bearing from pinion shaft using Remover J-6184 and Holder J-6274 (1956), Remove J-6531 and Holder J-7407 (1957-60), in a press or with Ram & Yoke Assembly J-6180. Pry pinion oil seal from carrier, being careful not to damage front Pinion bearing. If front pinion bearing is to be replaced, drive outer race from carrier using J-6198 and Handle J-872-5. If rear pinion bearing is to be replaced, drive outer race from carrier using Remover J-6256 with Handle J-872-5. *NOTE - The remover must be inserted in carrier before drive handle is screwed into it.*

9) If 1957-60 propeller shaft bearing is to be replaced place rear propeller shaft and bearing assembly in a press so that it is supported under bearing with shaft down. Using a sleeve or shaft slightly smaller than inside diameter of bearing, press universal joint yoke down through bearing. To install the new bearing, place rear propeller shaft in a press so that it is supported under both sides of front yoke. Start new bearing on yoke, then, using a heavy flat plate, press bearing on yoke until it bottoms against shoulder.

10) If rear universal joint is to be repaired, remove propeller shaft from torque tube. Rear universal joint can then be disassembled.



REASSEMBLY: *(NOTE* - Before installation of pinion and bearings, make certain that interior of carrier housing is clean and dry. Also make certain that parts to be assembled are clean and that pinion bearing shims are not burred. Bearings and oil seals should be lightly lubricated with rear axle lubricant just before assembly).

► *PROPELLER SHAFT NOTE: Propeller shaft should be checked for straightness (and straightened or replaced) before installation in rear axle assembly. See "Propeller Shaft Checking & Straightening" below.*

1) Drive front pinion bearing outer race against shoulder in carrier using Replacer J-6197 with driver handle. Drive rear pinion bearing against shoulder in carrier using Replacer J-6255 with driver handle.

2) Whenever a new carrier, a new pinion, or a new pinion bearing is used, a trial assembly must be made in order to determine correct pinion depth setting and pinion bearing pre-load *(see "Pinion Bearing Pre-load Adjustment" and "Pinion Depth Setting" below).*

► *CAUTION – Whenever a new pinion is to be installed, its depth setting must be gauged.*

BUICK HYPOID REAR AXLE

3) After pinion setting and pinion bearing pre-load have been correctly adjusted (if necessary) and front and rear bearings have been installed on pinion, lubricate new pinion seal with rear axle lubricant and install with lip toward bearing, using Installer J-6200. Reinstall pinion and bearings carefully into carrier with new thickness pre-load spacers. Install pinion nut and tighten to 80 ft. lbs. Recheck pinion setting with gauge. Recheck pinion bearing pre-load, which must not exceed 40 inch pounds including drag of lubricated new seal. Stake pinion nut securely.

4) On 1957-Early 1958 models, replace oil baffles and drive differential outer races into case, using Replacer J-6263. *NOTE - Side gear baffles eliminated in late 1958 and later cars. See "Late 1958-59 Rear Axle Housing Replacement Caution" above.* Install side gears, pinions and spherical washers in case *(CAUTION - There are no flat washers behind side gears).* If same parts are used, replace in original sides. Install pinion shield and pinion shaft. Drive spring pin through hole in pinion shaft until flush with case. Bolt ring gear to case, making sure mating surfaces are clean and free of burrs and that matching numbers on ring gear and pinion are the same. *NOTE - Use thru Studs, J-6251 to align parts.* If same ring gear and case are used, line up marks so that parts are assembled in same relative position *(do not use lockwashers or any substitute bolts).* Tighten bolts alternately on opposite sides of case to 25-30 ft. lbs., then tighten in same manner to 65-75 ft. lbs.

5) Before installation of ring gear and case assembly make sure that differential bearings and bearing support surfaces in carrier pedestal are clean and free of burrs. Remove any burrs which might prevent proper seating. Place case assembly and differential bearings in position in carrier. If original bearings are used, replace in original positions. Insert Support Tools, J-6194 (1956 Models), J-6194-01 (1957-60 Models) through the pedestal bores into the bearing inner races Press tools toward each other to seat them, using hand pressure. If support tools are loose, install pedestal clamp bolts and nuts and tighten lightly until support tools can just be moved by twisting them. If support tools are too tight, loosen them by wedging pedestals.

6) Rotate differential assembly three or four times to seat bearing rollers, then manually adjust the whole assembly sideways to get a .008" gear backlash. The assembly tools may be tapped lightly with a hammer to seat them. Check backlash as follows: Mount dial indicator so contact button bears against heel end of tooth on ring gear, and as nearly as possible in line

CONTINUED ON NEXT PAGE

1956-60 BUICK HYPOID (C nt.)

with gear rotation and perpendicular to tooth surface. Check backlash at three or four points around ring gear. Lash must not vary more than .003" around ring gear. If lash varies more than .003", check for burrs, uneven bolting conditions or distorted case flange, and make necessary corrections. *(CAUTION* - Gear backlash check must be made with pinion locked to carrier to be sure it cannot turn). Adjust gear backlash at the point of minimum lash to .008" for all new gears. If original gear set is being installed, maintain original backlash.

7) Measure with a shim between each bearing and its pedestal. Do not remove support tools for measuring. Select shim that measures .002" thicker than largest shim that can be inserted for each side, (this should pre-load each differential bearing .002"). The shims are furnished to be used singly in thicknesses ranging from .040" to .082" by two thousandths. Service shims are marked with their thickness in thousandths.

8) Remove support tool farthest from ring gear, insert shim for that side, and replace support tool. Place other shim in position for insertion. While keeping a heavy hand pressure on shim, spread carrier pedestals just enough to start shim, using Spreader J-6185 *(CAUTION - Do not spread pedestals any further apart than is absolutely necessary to push shim into position).* Leave support tool in position until after shim is started to keep case assembly from dropping out of line.

9) Remove left assembly tool and push shim into final position. Center it first with fingers through pedestal bore, then with a support tool. Remove spreader tool and pedestal wedges. Drive each differential bearing support into its pedestal until seated solidly in bearing, **using the Support Tool J-6194 for 1956 models or J-6194-01 for 1957-60 models. Then seat one support** solidly and tighten the clamp bolt and nut on that side to 50-60 ft. lbs. before proceeding to other side. This is to prevent shock caused when second support is seated from dislodging the first support. Secure nuts with cotter pins. Recheck backlash which must be .007-.009" at point of minimum lash, with not more than .003" variation around gear.

► *1956 SERIES 70 NOTE:* Rear axle oil pump has been discontinued in production and it is recommended that it not be reinstalled after rear axle has been disassembled for any purpose.

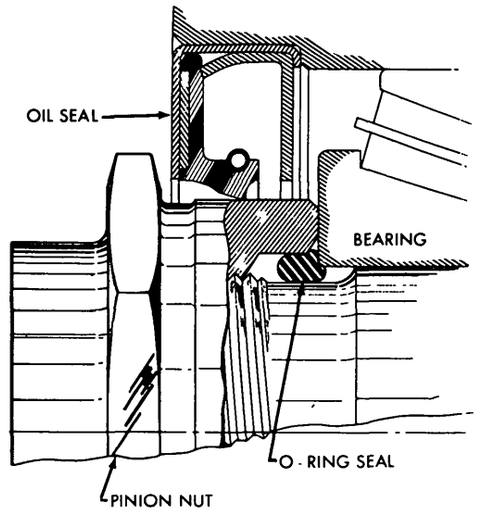
10) Before installing carrier assembly, make sure housing mounting surfaces are free of old gasket material, nicks, and burrs. Rotate axle housing so carrier mounting surface is upward and install a new carrier gasket. Install carrier in housing using Sling J-6247. Install nuts and tighten them evenly to 50-60 ft. lbs.

11) On 1956 model, check propeller shaft and pinion splines for wear and remove nicks or burrs. Replace propeller shaft seal sleeve if scored or grooved. Inspect propeller shaft rear packing and retainer and replace if worn or damaged. Pack rear propeller shaft coupling with heavy wheel bearing lubricant, bringing level to inner end of splines. Slide propeller shaft on splines.

12) Before installing torque tube, flanges on both ends must be free of burrs or nicks. Also, check torque tube mounting surface on carrier. Slide torque tube over propeller shaft being careful to keep torque tube centered on propeller shaft to avoid side thrust *(CAUTION - Propeller shaft will bend easily if side pressure is put on it).*

13) Position torque tube with strut rod bracket downward, being careful not to damage brake line. Install torque tube to carrier bolts and tighten alternately to 50-60 ft. lbs. *(NOTE* - There is no gasket used between torque tube and carrier). Connect brake line at tee on rear axle housing. Connect strut rods and tighten bolt to 85-100 ft. lbs. Install rear axle assembly in car.

14) On 1957-60 models, pack rear propeller shaft coupling with semi-fluid fibrous lubricant, bringing level to inner end of splines. Install rear torque tube carrier with brake return spring bracket down (no gasket is used). Tighten bolts to 50-60 ft. lbs. Rotate axle housing so that rear torque tube extends in a horizontal direction. Slide propeller shaft assembly into front torque tube until support bearing is seated against shoulder. Push front torque tube and propeller shaft assembly into place in rear torque tube. Rotate propeller shaft as necessary to engage splines. Position torque tube with strut bracket down (no gasket used between front and rear propeller shafts), and make sure that bearing retainer plate is in place. Install torque tube bolts and tighten to 65-75 ft. lbs. Connect strut rods and tighten bolts to 85-100 ft. lbs.



INSTALLATION: Reverse removal procedure. *See "Rear Axle" on Car Model pages.*

PINION BEARING PRE-LOAD ADJUSTMENT

► *NOTE: Whenever a new carrier, a new pinion, or a new pinion bearing is to be used, a trial assembly must be made in order to determine correct pinion depth setting and correct pinion bearing pre-load. Spacers used for pinion bearing pre-load and shims used for pinion setting will have to be changed for final adjustment*

1) For a starting pinion depth setting, use a pinion setting shim with a nominal thickness of .048". Place this shim against head of pinion and install rear pinion **bearing using Replacer J-6377, and Holder J-6407 with Ring J-6407-2 in a press.**

2) For a starting pinion bearing pre-load adjustment use a pair of spacers with a nominal thickness of .435". Place spacers in position on pinion and hold pinion in position in carrier. Install front pinion bearing and pinion nut. Hold nut to carrier with Holder J-6246 (Do not install seal at this time). Torque pinion nut to 80 **ft. lbs., using Torque Wrench J-1313 on outer end of Handle J-2646.** *NOTE - This amounts to an actual 250 ft. lb. torque at nut.* **Rotate pinion three or four times to seat bearings. Turn pinion slowly with an inch-pound torque wrench. Pre-load should be 10-30 inch lbs. If pre-load is under 10 inch-pounds a thinner spacer must be used or if pre-load is over 30 inch-pounds a thicker spacer must be used, under front pinion bearing.** *NOTE - Pinion Bearing pr -load spac rs ar furnished to b used in pairs s that p ssibl thickn ss s rang from .400" t .470" by thousandths. See tabl below.*

PINION NUT OIL SEALS (1959-60)

Pinion Bearing Pre-L ad Spac rs

Part No.	© Thickness	Part N .	© Thickn ss
1169104	.200"	1169386	.208"
1169105	.201"	1169387	.209"
1169106	.202"	1169388	.210"
1169107	.203"	1169389	.220"
1169108	.204"	1170158	.230"
1169109	.205"	1170159	.240"
1169110	.206"	1170160	.250"
1169385	.207"	1170161	.260"

© — Spacer thickness is marked on spacers.

3) *After pinion setting adjustment is completed (s e below)* change preload spacers by same amount that pinion setting shims were changed from the nominal setting. If thickness of pinion setting shims was **d - creased** .002", use pre-load spacers with .002" **less** thickness. If thickness of shim was **increased,** use pre-load spacers measuring .002" **thick r.**

4) Lubricate new pinion seal with rear axle lubricant and install with lip toward bearing, using Installer J-6200. Reinstall pinion and bearings carefully in carrier with "adjusted" thickness pre-load spacers, **Install pinion nut and tighten to 80 ft. lbs. using Torque Wrench J-1313 in outer end of Handle J-6246. Recheck pinion setting with gauge. Setting for new pinion must** be within .001" (1956), .0015" (1957-60) of setting marked on pinion. Setting for used pinion should be within .001" (1956), .0015" (1957-60) of original setting **(as checked before disassembly). Recheck pinion bearing pre-load with an inch-pound torque wrench. Pre-load must not exceed 40 inch-pounds including drag of lubricated new seal, stake pinion nut securely.**

PINION DEPTH SETTING

► *NEW PINION INSTALLATION CAUTION: Whenever a new pinion is to be installed, its depth setting must be gauged with Pinion Setting Gauge J-5647.*

CONTINUED ON NEXT PAGE

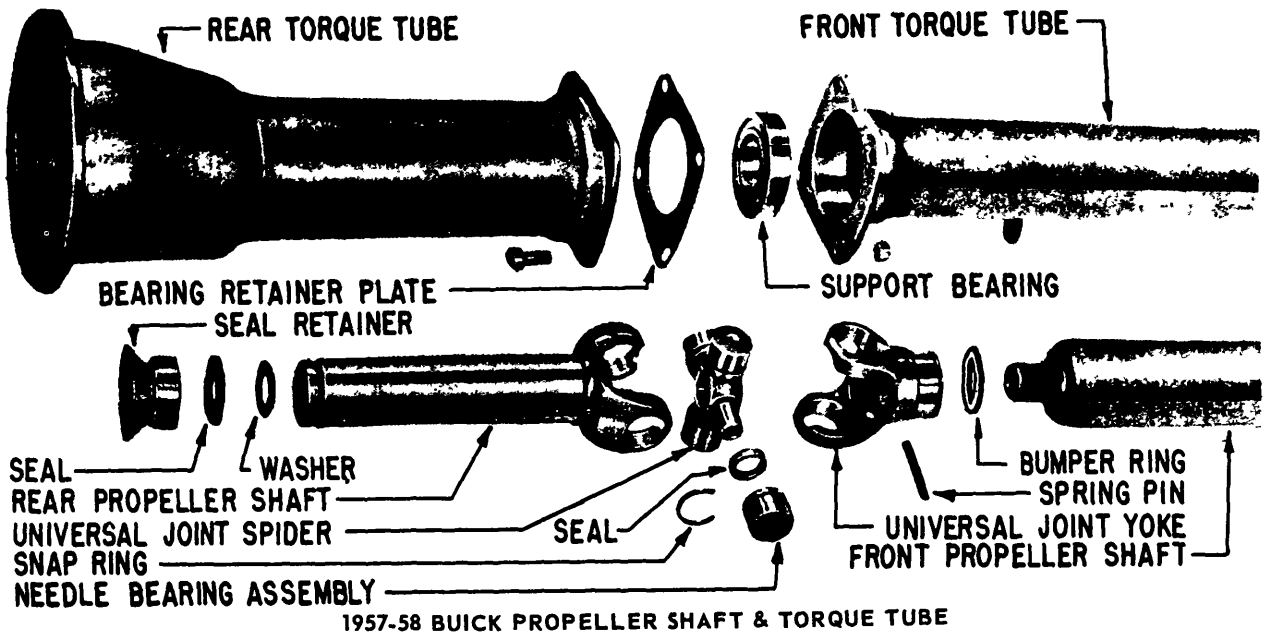
1956-60 BUICK HYPOID (C nt.)

CHECKING PINION DEPTH SETTING: After pinion bearing pre-load has been established (10-30 inch-pounds, without pinion seal installed) see above. Proceed as follows:

1) Use Pinion Setting Gauge J-5647 consisting of a "master gauge" and "indicator gauge" upon which a dial indicator is mounted. Make certain that gauge parts are clean.

2) Install discs on indicator gauge and install the small contact button on stem of dial indicator. Mount dial indicator on indicator gauge. Place indicator gauge on on master gauge so that spring loaded center is engaged in centering hole corresponding to the indicator pad "B", which is used for any of the following gear ratios **stamped on pinion: 43-11; 43-12; 47-14; 42-13; 43-14 (Pad "A" is used for certain prior model gear ratios).**

3) Center indicator contact button on specified indicator pad and lock indicator by tightening the thumb screw. Hold yoke firmly with both discs contacting the horizontal and vertical pads on master gauge, and set dial indicator at zero (make sure that differential bearing support bores are free of burrs and that center of pinion is clean).



4) *(NOTE* - There are two methods of taking a reading on the pinion setting gauge as follows:) When using the first method, the indicator gauge is zeroed in the master gauge by pressing down firmly on the indicator gauge yoke with the thumbs. It is important when using this method, that equal pressure is applied when taking the actual reading in the carrier. When using the second method, the indicator is zeroed in by pressing the discs into the angle formed by the master gauge. No pressure is applied to the indicator gauge yoke. Since the gauge is zeroed in with no pressure on the yoke, the actual reading is also taken with no pressure on the yoke. However, the adapters must be tight in the pedestal bores; if they are not held solidly in place after the wedges are removed, the pedestal bolts must be installed and tightened to specified torque, (50-60 ft. lbs.).

5) Rotate pinion until blank tooth between the matching number and the pinion setting mark is slightly counterclockwise of the center (at about 11 o'clock). This tooth is called the gauging tooth because it is used for located and gauging during production and should be used for gauging in service.

6) Drive a wedge into each pedestal split and spread them just enough so that an Adapter J-5647-17 will slip in. Then place the indicator gauge in carrier as follows: Remove discs from indicator gauge and hold it in position in carrier with pins centered in pedestal bores. Slide long adapter through pedestal bore farthest from pinion and over gauge pin. Then slide short adapter in place on other side. Be sure that gauge center is engaged in pinion center and that adapters are against shoulders of gauge. Then remove pedestal wedges. Turn pinion if necessary so that indicator contact button has a good contact with gauging tooth of pinion.

7) Take dial reading, noting whether it is plus (+) or minus (–) as indicated by arrows on surface of yoke. *(CAUTION - This reading does not indicate thickness of the shim to be used, but only indicates the variation from the nominal setting of the gauging face of pinion).* Recheck indicator "zero setting" on master gauge with discs to make sure it was not changed in handling.

8) If the old ring gear and pinion set is to be reinstalled and it has been in use long enough to establish a wear pattern on teeth, the original pinion setting found before removal should be maintained to avoid changing tooth contact. If ring and pinion set is new, or has not been used long enough to establish a wear pattern on teeth, the dial indicator reading should be within .001" (1956), .0015" (1957-60) of pinion setting marked on pinion. If pinion is not as specified, adjust as follows:

1957-58 BUICK PROPELLER SHAFT & TORQUE TUBE

PINION SETTING ADJUSTMENT: The pinion setting is adjusted by changing thickness of shim which is located between rear pinion bearing inner race and head of pinion. Shims are furnished as indicated in table below.

Pinion Setting Shims

Part No.	Ⓒ Thickness	Part No.	Ⓒ Thickness
1171083	.040"	1171093	.050"
1171084	.041"	1171094	.051"
1171085	.042"	1171095	.052"
1171086	.043"	1171096	.053"
1171087	.044"	1171097	.054"
1171088	.045"	1171098	.055"
1171089	.046"	1171099	.056"
1171090	.047"	1173482	.058"
1171091	.048"	1173483	.060"
1171092	.049"		

Ⓒ – Thickness is marked on shim.

1) Remove pinion assembly and press off rear pinion bearing using Remover J-6184 and Holder J-6274. Remove shim from pinion and wipe dry. Check thickness of shim to make sure it is correctly marked. Increase or decrease thickness of shim as required to obtain proper pinion setting.

2) Change pinion bearing pre-load spacers by same amount the pinion setting shims were changed, and finally install pinion assembly in carrier. *See "Pinion Bearing Pre-load Adjustment" above.*

CHECKING & STRAIGHTENING PROPELLER SHAFT (Using V-Blocks): Support shaft assembly (1956), front shaft only (1957-60) on V-blocks at each end (forward block just to rear of splines at forward end of shaft, rear block under splined coupling for 1956 models, or under spare seal sleeve placed over splines of rear coupling for 1957-60 models). Use a dial indicator to measure run-out at points 3" from end of shaft tube and at center of tube. Run-out should not exceed .006" at the ends or exceed .010" at the center. On the 1956 models, if run-out at the ends exceeds specifications, straighten tube by pressing on center of tube (support tube at same point at front end and under splined coupling at rear end as used for checking straightness). If run-out at center of tube exceeds specifications, straighten tube while supporting it on blocks at tube weld point at each end. Then check run-out at pinion coupling. If run-out exceeds .001", support shaft at forward end and at splined coupling at rear end and exert pressure at weld points on rear end of tube. Recheck all run-out points, then check run-out at extreme forward end of shaft (must be less than .002"). On 1957-60 models, if runout exceeds specifications, it is probably more economical to replace shaft than attempt to straighten it. However to straighten it, secure support blocks that conform to shape of the tube and the seal sleeve, apply pressure at high center of bend with shaft supported at both ends of bend. When corrected indicator reading at pressure point will be the same as at point 180° opposite.

CADILLAC HYPOID

Cadillac (1954-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*REAR AXLE SERVICE CAUTION* Manufacturer recommends that all service on the Differential Carrier Assembly other than oil seal or universal joint yoke replacement (and necessary pinion bearing preload adjustment) be handled by replacement of the complete assembly *No disassembly or adjustment of this unit should be attempted in the field*

►*REAR AXLE IDENTIFICATION MARKS* Gear ratio of axle is indicated by marking stamped on front face of carrier assembly at end of oil return passage Brougham rear axle assembly is identified by letter "B" next to gear ratio mark *See Car Model pages for ratios and markings*

►*PINION BEARING ADJUSTMENT CAUTION* Pinion bearing adjustment (preload) controlled by rear universal yoke nut which compresses spacer or sleeve between pinion bearings

►*CAUTION* Loosening or removal of the pinion shaft nut (for oil seal or yoke replacement) will disturb pinion bearing preload and exact procedure detailed below must be followed to avoid overloading bearings or collapsing bearing spacer

DESCRIPTION: Hypoid gear with Hotchkiss drive Differential housing is barrel type with provision made to remove and install pinions and side gears through right hand end (case closed by end cap screwed in housing and retained by locking screw or taper locking pin installed from outside of case) Differential assembly mounted in taper roller bearings (bearing cups seated in ends of differential housing) with threaded sleeve type adjusting nut at outer end of each bearing Adjusting sleeves are locked by clamp bolt in each bearing post

REMOVAL OF AXLE: *See Rear Axle on car model pages*

PINION OIL SEAL OR UNIVERSAL YOKE REPLACEMENT:

►*CAUTION Pinion bearing preload (turning torque) must be measured before pinion shaft nut loosened*

Pinion Bearing Oil Seal Removal: 1) On Air Suspension Cars, pull out lift valve control handle on instrument panel Raise rear end of car, remove both rear wheels and brake drums (to eliminate drag while taking torque reading) Drain about 1½ pints of axle lubricant with suction gun and disconnect rear universal joint and pinion yoke

2) Measure inch-pounds torque (use 50 inch-pound wrench) required to rotate pinion shaft slowly for at least two turns **N t r ading**

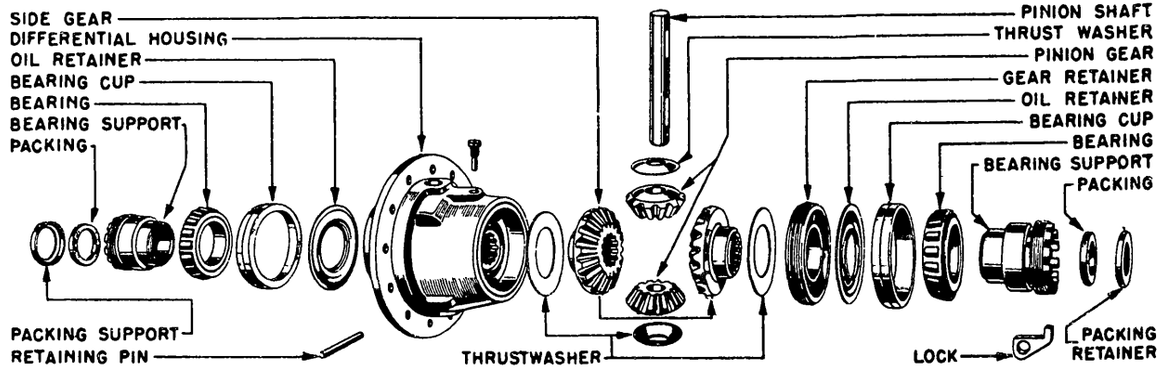
3) Mark pinion shaft and yoke with punch (to be installed in same position) Hold yoke and remove pinion nut Pull pinion yoke from pinion shaft Remove pinion seal, then remove staking burrs on pinion shaft with small file or a 7/8-14 thread die

Installation of Oil Seal: 1) Coat outer edge of seal with non-hardening gasket sealer and lubricate sealing lip Drive seal into carrier *CAUTION - Be sure that outer surface of yoke is free from scratches or nicks*

2) Line up punch marks and install yoke on pinion shaft Install new pinion nut and tighten it until preload at time of removal is obtained, **plus** 2-5 inch-pounds Rotate pinion shaft while tightening pinion nut approximately ½ turn at a time until correct preload torque is obtained Repeat torque operation *CAUTION - DO NOT overtighten pinion nut and never back off nut to reduce preload torque See Pinion Bearing Preload below*

3) Stake pinion shaft nut, connect rear universal joint at pinion yoke and refill rear axle to correct level

4) Replace brake drums and rear wheels Lower car and push in on Air Lift Control



Pinion Bearing Preload
(Pinion Shaft Turning Torque)

New Assembly	50 inch-pounds max
After 1,000 miles (used oil seal)	15 inch-pounds max
After 1,000 miles (new oil seal)	20 inch-pounds max

AXLE SHAFT REPLACEMENT: Axle shaft is "flanged" type which does not have separate wheel hub (brake drum and wheel bolted directly to shaft flange) On 1954-56 models, install new oil seal whenever seal is removed

Axle Shaft Removal & Installation - With wheel off, take out retaining screws and remove brake drum Remove nuts and lockwashers mounting bearing retainer and backing plate on rear axle housing Use Puller, Tool No J-8131, (J-942-1) with slide hammer Tool J-2619 to remove axle shaft using care not to damage oil seal (1954-56) or disturb position of backing plate

►*WHEEL BEARING REPLACEMENT NOTE* On 1954-56 models, bearings are sealed type and pre-lubricated and should be inspected for loss of lubricant A bearing that spins freely (indicating loss of lubricant) should be replaced On 1957-60 models, oil seal is an integral part of bearing and is not serviced separately Bearing is lubricated by rear axle lubricant

CADILLAC REAR AXLE ASSEMBLY

WHEEL BEARING REMOVAL & INSTALLATION: Use cold chisel and hammer to nick spacer next to bearing (not necessary to split spacer), slip spacer off shaft Use Special Bearing Remover & Replacer Tool J-2986 (place "U" shaped part of tool under bearing to prevent it exploding) Press bearing off shaft in arbor press Install bearing on shaft with seal toward flange end of axle shaft (1957-60) with same tool, pressing bearing on until it does not quite touch shoulder on shaft Then press new spacer on shaft against bearing On 1957-60 models, install "O" ring seal in grooved outer surface of bearing

AXLE SHAFT OIL SEAL REPLACEMENT (1954-56): Make certain that all nicks or burrs removed from counterbore into which seal fits Polish shaft on which seal leather bears Dip new seals in clean engine oil, coat inner surface of oil seal leather with chassis lubricant, coat outer surface of oil seal metal shell with sealer compound Use Tool J-3069 to install seal in housing

DIFFERENTIAL CARRIER ASSEMBLY OVERHAUL: Manufacturer recommends that all services other than oil seal or universal joint yoke replacement (above) should be handled by replacement of the assembly No attempt should be made to disassemble or adjust the carrier assembly in the field

Carrier Assembly Installation - When installing carrier, tighten capscrews to 30-35 ft lbs If oil leaks noted between carrier flange and housing, correct by installing extra gasket at this point with sealing compound on gaskets **Do not tighten capscrews exc ssively to correct oil leaks**

Checking Backlash - Raise car on hoist and fasten one end of piece of bar stock to yoke on pinion shaft and the other end to frame side rail by means of "C" clamps to prevent rotation of drive shaft. Apply emergency brake cable on one wheel to hold wheel stationary, and measure backlash in inches at outer circumference of tire tread A stiff wire pointer fastened to fender of car will aid in this measurement Maximum backlash at wheel should not exceed ½"

1954 CHEVROLET PASSENGER CAR HYPOID

Chevrolet Pass. Car & ½-Ton Truck (1954)

►CHANGES, CAUTIONS, CORRECTIONS

►**PINION BEARING LOCK SLEEVE LOCKSCREW INSTALLATION CAUTION:** Both sleeve face and tapered end of Lockscrew should be coated with Rear Axle Lubricant when these parts installed to prevent screw cutting or scoring face of sleeve when screws are tightened. CAUTION—If these parts not lubricated, and screw cuts face of lock sleeve, screw may bottom without forcing sleeve into position against bearing which may cause failure of pinion bearings or ring and pinion gear due to incorrect adjustment.

►**REVACYCLE DIFFERENTIAL PIN & SIDE GEARS (Not used on Half-Ton Truck Models)**—Revacycle gears must be used together and must not be interchanged singly with other type gears.

►**UNIVERSAL JOINT & PROPELLER SHAFT BUSHING LUBRICATION CAUTION (Powerglide Cars):** These parts lubricated from Powerglide transmission output shaft through oil passage in special drilled universal joint retaining bolt No. 3690869 (bolt drilled completely through and has special flat head nail inserted in hole to keep oil passage open). If universal joint or bushing lubrication troubles experienced, **make certain that drilled bolt used and that nail is free in oil passage** (1/32-1/16" clearance between head of nail and head of bolt).

►***CAUTION—Plain bolt used for transmission run-in at factory must be replaced by this special drilled bolt when transmission installed in car.***

►**AXLE IDENTIFICATION & RATIO NOTE**—See Chevrolet Car Model pages for axle ratios and identification.

DESCRIPTION: Hypoid gear, semi-floating type with torque tube drive.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT: Check endplay when installing axle shafts (see below).

Axle Shaft Removal—Remove wheels, take out both 'zipon' nuts mounting brake drum to axle shaft flange and remove drum. Remove axle housing rear cover, take out pinion shaft screw, withdraw pinion shaft, lift out axle spacer block. Push shafts in toward center of housing, remove "C" washers at inner ends within differential side gears, withdraw axle shafts. When replacing shafts, check endplay.

Axle Shaft Note—Axle shafts are of unequal length. ***See Chevrolet Special Data in car model section for shaft part numbers and identification marks.***

CAUTION—Install longer axle shaft on right side.

New Axle Shaft Installation. Wheel hub bolts are press fit in axle flange and must be installed in new shafts (these bolts hold oil deflector assembly on flange). Coat new gasket with heavy shellac or paint, install gasket and oil deflector on flange lining up oil holes (extra center hole of three closest together should be lined up with notch in flange, oil pocket in deflector should also line up with this notch), insert special wheel bolts and force heads down to deflector, peen shoulder on bolts into countersink around bolt holes in flange (this is very important). Check shaft endplay.

Axle Shaft Endplay (Passenger Cars)—Controlled by spacer assembled on differential pinion shaft between inner ends of axle shafts. Endplay should be from a free fit to .014" maximum. Select correct spacer block (see data below) to give this endplay. Install spacer block with ground faces of block toward axle shaft ends. NOTE—Medium spacer block ground on all four sides and may be installed either way to secure either of these two sizes.

Part No.	Pass. Car Spacer Blocks	Size
597251		Narrow (1.012")
473603		(1.0195" & 1.0295")
597254①		Wide (1.0345")

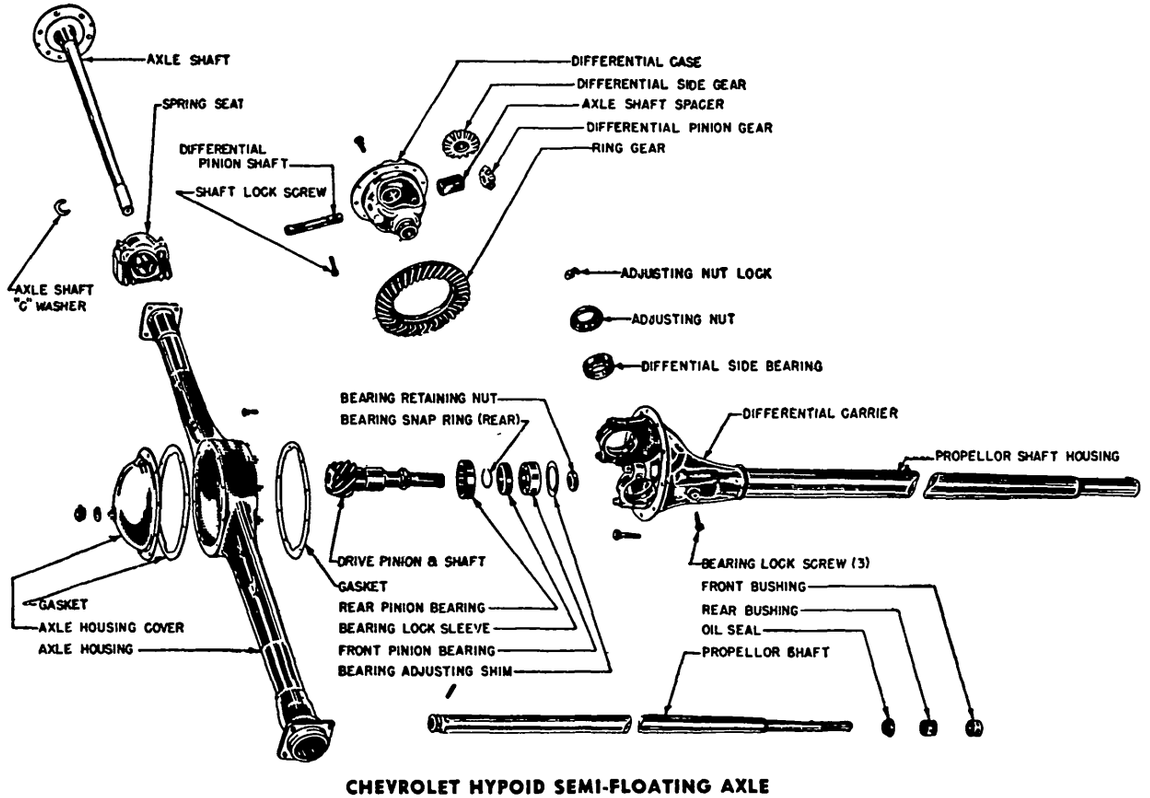
Axle Shaft Endplay (Trucks)—Same as for Passenger Car (above) except that spacer blocks furnished in two types for three sizes as listed below (wide block ground on all four sides, may be installed either way).

Part No.	Truck Spacer Blocks	Size
370217		Narrow (1.1485")
372515		Wide (1.1575" & 1.1675")

Axle Bearing & Oil Seal Installation—Before installing new parts, make certain that axle housing is clean and smooth (remove old staking marks), coat outer diameter of seal retainer lightly with Permatex (use care not to get Permatex on seal). Assemble bearing, retainer, and oil seal on end of driver, seat parts in place in housing with few light blows of a hammer on the driver. Remove tool, stake oil seal in place with a prick punch. NOTE—Spring-loaded type seals are not staked.

PROPELLER SHAFT & FRONT BEARING: Propeller shaft is part of pinion and shaft assembly (see "Overhaul" data following).

►*PROPELLER SHAFT BUSHING NOTE:* Bushings used in production in torque tube are finish-ground after installation to prevent possibility of interference between torque tube and torque ball sleeve. Use press fit type replacement bushings and remove and install bushings as follows:



"Press Fit" Bushing Removal & Installation - Use special Puller J-4258 to remove both bushings and oil seal from torque tube. Install new parts in following order: Oil seal (use Driver J-968, placing seal on driver with free side of leather toward head of driver), rear bushing (use Driver J-4259 with spacer washer on driver), front bushing (use Driver J-4290). Drive bushings in until stop on driver is against end of torque tube. Drivers will position bushings correctly. *CAUTION - If new bushings not a tight fit in old torque tube, bushings should be drilled and dowel pins installed.*

Replacement Torque Tube Bushings: Part No. 3694732 (Front); 3694733 (Rear).

►**Oil Seal on Powerglide Cars**—Special rubber-encased seal used to prevent oil leaks around outer diameter of seal retainer. This seal is Part No. 3691457 and is used in this 3.55-1 Ratio axle only.

OVERHAUL: Disassembly—Drain lubricant and remove rear housing cover. Remove axle shafts (see

CONTINUED ON NEXT PAGE

CHEVROLET HYPOID SEMI-FLOATING AXLE

1954 CHEVROLET HYPOID (C ntinu d)

data above). Remove nuts retaining torque tube on axle housing, remove torque tube, propeller shaft and pinion assembly. Remove adjusting nut locks on differential side bearing caps, remove bearing cap screws. Remove bearing caps and adjusting nuts, lift differential assembly out. Dismantle and service sub-assemblies as follows:

Pinion Bearing & Propeller Shaft Assembly: To remove from torque tube, loosen locknuts and take out retaining screws on side of housing, withdraw assembly from torque tube. To dismantle assembly, drill out head of rivet pin in propeller shaft, loosen pinion bearing locknut, disassemble pinion from propeller shaft. Use J-996 pinion bearing remover to press double row ball bearing from pinion shaft, remove locking sleeve or bearing retaining collar, remove lock ring from pinion shaft, take off roller bearing. Front double row ball bearing must have no perceptible endplay (new bearings may be .001" tight or have some drag). Assemble in reverse order making certain that lock ring installed on shaft ahead of roller bearing (to prevent rollers creeping) and that locking sleeve installed with beveled edge towards pinion. Tighten bearing locknut to 200-240 ft. lbs., stake nut in shaft slot. Use new rivet pin when assembling pinion and propeller shaft and rivet both ends of pin securely. Make certain that pinion setting shims installed in housing (see Pinion Setting below), insert propeller shaft assembly with spacer J-4050 between pinion and roller bearing to maintain proper pinion-to-bearing clearance, drive assembly down to seat bearings properly (use drift in hole in end of pinion, do not drive on end of pinion teeth). Make certain that locking sleeve down against front bearing, install the three tapered lockscrews, tighten these screws evenly and securely, tighten locknuts.

►*CAUTION*—Coat beveled face of pinion bearing lock sleeve and tapered ends of lockscrews with rear axle lubricant before installing to prevent screws cutting or scoring sleeve which would cause incorrect axle adjustment and early failure of bearings and gears.

►*HALF-TON TRUCK PINION BEARING ASSEMBLY NOTE:* Install bearing oil seal retainer on shaft next to rear roller bearing, with bevel of large diameter of retainer toward pinion, and ahead of bearing lock sleeve.

Pinion Setting:—Pinion position controlled by shims installed in housing ahead of front bearing. Standard assembly .033" shim thickness (one .015" shim, one .018" shim) and should be used for new gears. Shim pack can be varied from .024" to .042" and shims are furnished as follows:

Part No.	Pinion Setting Shims Thickness
3657740	.012"
3657741	.015"
3657742	.018"
3657743	.021"

Differential Bearing Assembly:—Use special puller to remove bearings from differential case hubs (notches provided in case for puller so that pressure applied to inner races only). Use J-994 bearing replacer to install bearings. When installing differential assembly in carrier (third member), make certain that marks on bearing caps and carrier line up

Differential Bearing Adjustment:—With carrier or third member assembly out of axle housing, tighten differential bearing cap screws until lockwashers are just flattened, turn right hand adjusting nut up until it is just snug, then turn nut additional 1-2 notches to locking position, tighten bearing cap screws evenly to 65-80 ft. lbs. (Pass. Cars), 115-135 ft. lbs. (Half-Ton), install adjusting nut locks.

Ring Gear Backlash Adjustment. To set up differential assembly for correct backlash when installing assembly in carrier, turn left hand adjusting nut in slowly until all backlash between ring gear and pinion taken up (revolve ring gear while making this adjustment), then back adjusting nut off one notch. Adjust differential bearings by turning right hand adjusting nut as directed above. This setting should give correct backlash of .005-.007". After bearing adjustment completed, recheck backlash and if not correct, adjust by backing off one adjusting nut and tightening opposite nut exactly the same amount to avoid disturbing bearing adjustment.

Ring Gear Replacement:—Run-out of differential case flange must not exceed .001" with ring gear removed. When installing ring gear, use guide pins in alternate bolt holes to position gear while bolts are being installed, use new lockwashers under bolt heads, tighten all bolts evenly to 40-60 ft. lbs. (Pass. Cars), 85-95 ft. lbs. (Half-Ton). Check ring gear run-out which should not exceed .0035" (measured on back face of gear).

1955-60 CHEVROLET HYPOID (HOTCHKISS DRIVE)

Pass. Cars, El Camino, Sed. Del. (1955-60)
Corvette (1954-60)
½-Ton Trucks (1955-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955-60 PASS. CAR REAR WHEEL BEARING NOTE:* Either roller or ball type bearings are available for service. Roller type (high capacity) are recommended for use when wheel bearing maximum service life is desired. Roller bearings are available as follows: Part No. 7550792 (1955-56); Part No. 7451112 (1957-60).

►*1956 PASS. CAR WHEEL BEARING NOTE:* Bearing and axle shaft seal are serviced as an assembly. The bearing is permanently lubricated and no further lubrication is required. Install with spring loaded lip toward axle shaft retainer.

►*1955-57 PINION FLANGE OIL SEAL INSTALLATION CHANGE:* When installing the seal, do not bottom it against shoulder in differential bore. This could cause distortion and damage to seal. It is recommended that the seal be pressed to a depth in carrier housing that permits face of seal case to protrude 3/16" to 7/32" from housing.

►*1955-56 RING GEAR & PINION NOTE:* The 1956 wider ring gear and pinion sets may be used on 1955 models for service replacement.

►*1957 REAR WHEEL BEARING REMOVAL PROCEDURE CHANGE:* Due to clearance restrictions, Press Plate Tool 5741, will not fit properly on the 1957 axle. *See "Overhaul" below for revised procedure.*

►*1955-60 REAR WHEEL BEARING GASKET SERVICE REPLACEMENT NOTE:* The single thick gasket formerly used has been replaced by two thinner gaskets, Part No. 3772374 & 3775360, which must be installed together. These new gaskets are installed on both sides of rear brake flange plate, adjacent to axle housing on the inside and bearing retainer on the outside.

►*1959 CORVETTE DRIVE LINE VIBRATION CORRECTION:* This condition may be due to excessive rear universal joint angle and can be corrected by installing either a 3° shim, Part No. 3744488, or a 2° shim, Part No. 3722797, between rear axle pad and spring on both sides, with thick edge of shim toward front. *NOTE - Locating tab on shims should be removed to allow shim to lie flat. See "Propeller Shaft Notes" in Chevrolet Special Data.*

DESCRIPTION: Semi-floating, hypoid gear type with Hotchkiss drive. Drive pinion is mounted on preloaded tapered roller bearings. Power-Lock Differential optional on 1957-60 models.

►*PINION BEARING PRELOAD CAUTION:* Pinion bearing preload must be adjusted whenever universal flange nut on pinion shaft loosened (preload controlled by this nut and will be disturbed when nut loosened).

REAR AXLE ASSEMBLY REMOVAL: *See "R ar Axl " n Car Mod l Pag s.*

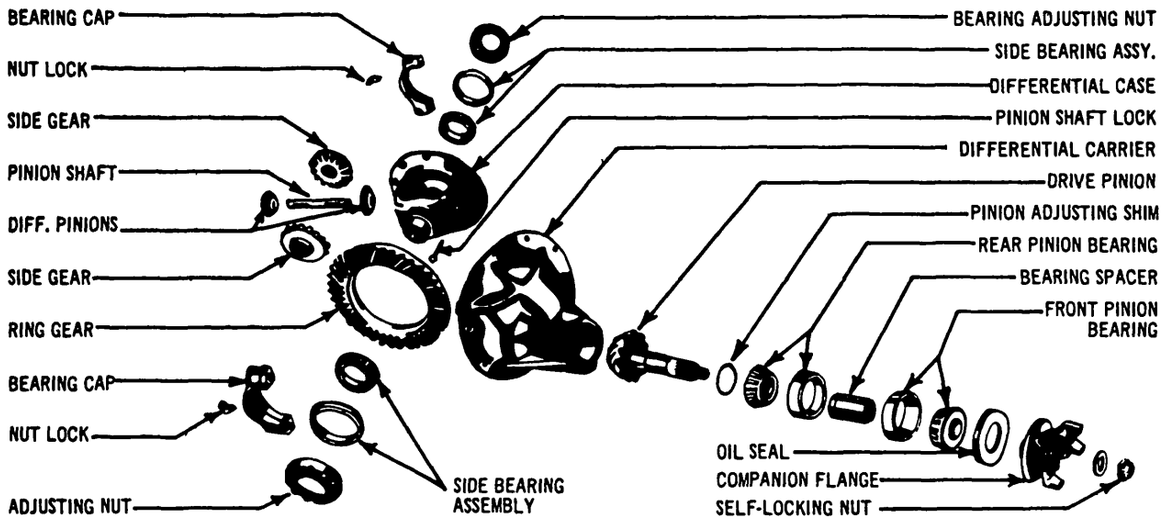
AXLE SHAFT REPLACEMENT (PASS. CARS): R m val - Raise car, place jack stands under rear axle housing. Remove hub nuts and remove tire and wheel. Remove brake drum and gasket. Remove nuts and lockwashers from bearing retaining bolts on inside of axle flange. Attach axle puller J-5748 with slide hammer to hub nuts and remove axle and bearing assembly, being careful not to disturb backing plate *(NOTE*—If bearing retainer and parking brake strut interefere, raise strut slightly for clearance). Install bolt and nut to hold backing plate on axle housing.

Bearing or Oil Seal Replacement—Using a hammer and chisel, nick the soft ring next to bearing and remove ring *(NOTE*—It is not necessary to split the ring completely for removal). Install press plate J-5741 between axle flange and bearing with the land of the plates against bearing and inside the retainer. Install bolts in plates. Press bearing from shaft with press plate parting line resting on press bed *(CAUTION*—Press plates must be supported on parting line). On 1957-58 models, support rear wheel bearing retainer and knock the four serrated bolts from retainer. Slide retainer down against axle flange and install Press Plate Tool 5741 on axle shaft between bearing retainer and bearing and fully close the two plate halves. Replace bearing on shaft with retainer ring chamfered side against bearing. When roller bearing used, install inner race on shaft and

CONTINUED ON NEXT PAGE

1955-60 CHEVROLET HYPOID (C ntinued)

press in place with "flat" side of Tool J-6661. *NOTE* - Seal must be in place on bearing. Use "flat" side of Tool 6661 to install roller bearing retainer ring. *NOTE* - New roller bearing is a one-piece assembly. On older models, pry out old seal being careful not to damage bearing races. Install new seal using guide Tool J-5747. Tap seal in place with plastic hammer. Install bearing with installer, Tool J-5746, so bearing seats on shaft against shoulder. On 1959-60 models, a second retaining ring is used which must be pressed on shaft.



(CAUTION–Bearing retainer must be on shaft before bearing installed). Install new axle shaft bearing retaining ring on shaft with tool J-5746 to seat ring against bearing (chamfered side of ring must be against bearing).

►*AXLE SHAFT REPLACEMENT NOTE:* If a new shaft is being installed, insert the five new special bolts and force heads down to flange on axle. Peen end of shoulder on bolts into countersink around holes in flange using tool J-554. Install new bearing (see above).

Installati n: Replace bearing "O" ring seal. Remove temporary nut and bolt holding brake backing plate in place. Install new retainer gasket and install axle shaft in housing using axle shaft tool J-5748 and slide hammer. Rotate shaft to align splines of shaft and differential side gear. Outer race of bearing must seat against shoulder in axle housing. Install nuts and lockwashers on bearing retainer bolts and tighten securely. Install brake drum gasket, drum, wheel and hub nuts.

AXLE SHAFT REPLACEMENT (½ Ton Truck): Removal - Remove wheel and brake drum, drain lubricant from differential and remove housing cover. Remove differential pinion shaft lock screw, pinion shaft, axle shaft spacer, and differential pinions. Push axle shafts inward to remove "C" washers from inner ends of axle shafts, then remove shafts from housing.

Installati n - Install gasket to flange with center hole (of three holes closest together) aligned with notch in flange. Use heavy shellac or paint on both sides of gasket and oil deflector. Install oil deflector aligning oil pocket with notch in flange. Insert six special bolts, forcing heads down to deflector. Peen shoulder on bolts into countersunk holes in flange with anvil and hub bolt Tool J-554. Check leather oil seal for wear, damage or misplacement. Slide axle shaft into place. *NOTE - DO NOTdamag l ath r il seal when inserting axle shaft and b sur shaft inner splines engage splines of diff r ntial sid g ars.* Replace "C" washers. Spread shafts, but DO NOT damage inner ends of shafts when forcing "C" washers and shafts into counterbores in side gears, then install differential pinions. Select and install spacer to give .014" clearance between ends of axle shaft and spacer. Spacers available in three sizes as follows: Narrow (1.147-1.150"), Medium (1.156-1.159"), Wide (1.166-1.169") wide across ground surfaces. Assemble pinion shaft with lockwasher under head of lock screw. Use new gasket and reinstall housing cover and refill differential. When installing brake drum, be sure that lug in web section is aligned and extends into drain hole in axle shaft flange.

CHEVROLET HYPOID REAR AXLE (HOTCHKISS DRIVE)

Bearing or Seal Replacement - Remove wheel and axle shafts, see above, then use Puller J-1436-A or J-8119 to remove bearing, bearing retainer, and oil seal. Inspect bore and remove old stake points. *NOTE* - If stake points not removed they will make groove in new seal and cause lubricant leak. Place oil seal, bearing, and inside bearing retainer on Tool J-270-7 in that order. Use Permatex No. 2 on oil seal outer diameter. *CAUTION - DC NOT get sealer material on leather lip of oil seal.* Start bearing into housing and tap on tool to seat parts. Remove tool and stake oil seal in place with prick punch. Assemble axle shafts, see above

COMPANION FLANGE, OIL DEFLECTOR OR SEAL REPLACEMENT: Removal–Raise one rear wheel off floor with jack stand placed under frame side rail. *(NOTE–This is to lock one rear wheel and obtain differential to body clearance. If operation is to be performed on a hoist, support frame on jack stands, allow axle to drop for clearance and expand brake shoes on one wheel to lock it securely).*

1) Check free wheel for freedom of rotation. Separate rear universal joint, tape trunnion bearings to joint and drop propeller shaft to floor.

2) Using an inch-pound torque wrench on the companion flange nut, rotate pinion through several complete revolutions and record the torque required to keep pinion turning. If old flange is to be installed, mark pinion and flange for reassembly in the same relative position.

3) Hold drive flange using tool J-2637-A, remove companion flange nut and special washer. Discard nut and use a new one at reassembly. Remove drive flange using tool J-820-A bolted over holding tool J-2637-A. Pry oil seal out using a screwdriver or hammer and chisel. Inspect drive flange for smooth oil seal surface or worn drive splines. On new flanges or old flanges with damaged deflectors, install new deflector, using tool J-5749.

4) Soak new seal in light engine oil for 10 minutes before installation. Wipe outer diameter of seal and then coat outer diameter with Permatex No. 3 or similar sealer. Install seal using tool J-5154.

5) Install drive flange, aligning marks on pinion and flange if old flange is being used. If flange does not go on shaft easily, use tool J-5780 to pull it on.

►*CAUTION: Do not hammer flange on pinion shaft as damage to ring gear and pinion will result.*

6) Install washer and a new self-locking nut. Tighten nut to remove endplay and continue alternately tightening in small increments and checking preload torque with inch-pound torque wrench until it is the same as recorded at disassembly. Readjust brake if it was expanded to hold wheel.

OVERHAUL: Differential Carrier Assembly Removal - Remove axle shafts, see above, just far enough to clear carrier. Remove nuts and copper washers that attach carrier to axle housing. On passenger cars, separate carrier from housing just enough to drain lubricant, then remove carrier.

►*1956 PINION SHAFT REMOVAL NOTE:* Interference may be encountered on some models while pinion shaft is being removed. If pinion shaft will not clear ring gear, ring gear must be removed to avoid damaging teeth while pinion shaft is being removed.

CONTINUED ON NEXT PAGE

1955-60 CHEVROLET HYPOID (C ntinued)

Disassembly: Mount carrier assembly in a vise or fixture J-3289. Mark caps and carrier for reassembly in same position. Remove differential adjusting nut locks and bearing cap bolts. Remove bearing caps and adjusting nuts by tapping on bosses of caps until free from dowels. *(CAUTION–Do not pry caps off as this may damage machined face of cap).* Remove differential and ring gear assembly from carrier housing being careful not to drop side bearing outer races. Remove differential pinion shaft screw and lockwasher and differential pinion shaft from case, and remove pinions and side gears. Hold companion flange from turning with tool J-2637-A and remove propeller shaft pinion flange nut and washer. Remove flange with tool J-820-A, bolted to flange with holding tool in place. Remove pinion from carrier by tapping on front end with soft hammer. Remove pinion shaft oil seal, pinion front bearing and bearing spacer from carrier. *(NOTE–*Some axles may have a 1/16" shim located behind spacer. This is a production item only and should be discarded).

Inspection: Wash all parts in cleaning solvent and thoroughly clean axle housing. Inspect all bearing cups, cones and rollers for chipping or evidence of excessive wear. On pinion bearing rollers, inspect large end of rollers for wear *(NOTE–*The pinion bearings are preloaded, and the natural wear pattern is a frosted condition with occasional slight scratches on races or rollers. This does not indicate a defective bearing). Inspect oil seal for wear or damage and pinion shaft splines and flange for excessive wear. Inspect ring gear and pinion teeth for scoring, cracking or chipping and differential case for cracks or scores on side gear and pinion thrust faces. Check fit of differential side gears in case and fit on axle shaft splines. Inspect differential pinion shaft for scoring or evidence of excessive wear. Inspect carrier for cracks or crossed threads on bearing caps and bosses.

►*PINION MARKING & PINION SETTING TOOL NOTE:* The number marked on pinion shaft (39 to 51 on 1955) or (40 to 50 on 1956-60), will indicate in thousandths, the pinion mounting distance. A new Rear Axle Pinion Gauge J-6266 is used with 1956 and later models with the above pinion markings, to obtain accurate adjustment. *NOTE - Gauge J-6266 must not be used on 1955 or earlier models.*

Drive Pinion Bearing Replacement: Remove front and rear bearing outer races from carrier with a brass drift. Install new bearing cups in carrier using tool J-270-6 on front cup and J-270-14 on rear cup, driving bearing races in until they seat against shoulders in housing. Remove rear pinion bearing inner cone and roller assembly using tool J-5740 press plate, in an arbor press *(CAUTION–N t siz f shim r m v d fr m b tw n c n and g ar).* If original ring gear and pinion are being reinstalled in the original carrier, install the original shim pack. If a new ring gear and pinion, or a new carrier is being installed, see *"Pinion Gear Setting" below.*

Pinion Gear Setting (1955): When installing a new pinion gear or differential carrier, determine correct amount of shims to install between pinion gear and bearing by checking the markings on end of pinion gear and on carrier flange face, and then referring to Pinion Shim Table below. Carrier is marked S-1, D-1 etc., and pinion gear is marked +1, -1 etc. As an example, a +1 pinion in a S-1 carrier should have a .030" shim.

Pinion Shim Table

Pinion Mark	Carrier Mark S-3	S-2	S-1	0	D-1	D-2	D-3
-5	.024"	.024"	.024"	.027"	.027"	.027"	.027"
-4	.024"	.024"	.024"	.027"	.027"	.027"	.030"
-3	.024"	.024"	.027"	.027"	.027"	.030"	.030"
-2	.024"	.027"	.027"	.027"	.030"	.030"	.030"
-1	.027"	.027"	.027"	.030"	.030"	.030"	.033"
0	.027"	.027"	.030"	.030"	.030"	.033"	.033"
+1	.027"	.030"	.030"	.030"	.033"	.033"	.033"
+2	.030"	.030"	.030"	.033"	.033"	.033"	.036"
+3	.030"	.030"	.033"	.033"	.033"	.036"	.036"
+4	.030"	.033"	.033"	.033"	.036"	.036"	.036"
+5	.033"	.033"	.033"	.036"	.036"	.036"	

Pinion Gear Setting (1956-60): If original ring gear and pinion, pinion rear bearing assembly and differential carrier will all be reinstalled, the original shim or one of the same thickness may be used. If the ring gear and pinion, pinion rear bearing assembly or differential carrier are to be replaced, the correct thickness of the pinion depth shim may be determined as follows:

1) Lubricate pinion bearing cone and roller assemblies with rear axle lubricant. Position rear bearing in its cup in carrier. Rotate bearing several times to make sure it is seated. Position gauge plate (part of Tool J-6266) on bearing so that the chamfered corner is toward pinion side and top of differential as installed in car.

2) While holding front cone and roller assembly in its cup with the clamp plate, insert the clamp screw (part of Tool J-6266) through the gauge plate, both bearings and clamp plate. Tighten only a sufficient amount to center bearings in cup. Check to see that neither gauge block nor clamp plate touch the housing. Oscillate gauge plate and bearings several times to be sure bearings are seated and then draw up hex nut until 20 inch-pounds of torque are required to oscillate plate and bearings. *(NOTE* - A torque of 60 ft. lbs. may be required to tighten nut on clamp bolt in order to obtain simulated preload of bearings after assembly. After tightening clamp bolt nut, measure turning torque with an "inch-pound" torque wrench).

3) Install Tool J-6266 body assembly across differential bores. Plunger on body must point inward toward center of pinion rear bearing. Mount a dial indicator, KMO-30 on tool body post with indicator button on top of tool plunger. Swing body so that plunger d s n t touch gauge plate. and set dial indicator at zero.

4) Slowly swing inner end of tool plunger across gauge plate until highest indicator reading is obtained. Record this measurement and recheck to see that it is correct. Record factory marking on pinion. **Subtract** the measurement obtained with the tool from marking on pinion. The **difference** between these two figures determines thickness of pinion depth shim to be installed with the particular pinion and ring gear, and rear bearing and carrier being checked. Shims are available in six different thicknesses: .021", .024", .027", .030", .033" and .036". Use the shim which is closest to the difference in measurement.

5) Remove indicator, tool, and pinion rear bearing cone assembly from carrier. Position the shim selected, between pinion gear head and rear pinion bearing with tangs on shim toward pinion head.

Differential Bearing Replac ment: Install differential bearing puller TR-278-R, making sure that puller legs are fitted securely and retaining yoke is tight. Tighten puller screw and remove bearing. Install a new bearing on hub with the thick side of inner race toward case and drive in place with tool J-5768 *(NOTE–*This tool is counterbored and has a pilot to assure proper installation and seating of bearing).

Ring Gear & Differential Cas R plac ment: Remove ring gear bolts and lockwashers and using a soft hammer, tap ring gear off the case. Install guide pins made from 3/8"-24x1½" long capscrews with heads cut off and ends slotted, in alternate bolt holes in ring gear. Make sure back face of ring gear and face of case are free of dirt and burrs. Mount case on "V" blocks placed at side bearings and check face runout with a dial indicator. This should not exceed .003". Drop ring gear over pilot diameter of the case, then install every other ring gear bolt and lockwasher and draw them up evenly and snugly so that ring gear face is flush with face of case. Remove guide pins and install remaining bolts. Tighten all bolts to 40-60 ft. lbs.

Differential Carrier Reass mbly: Mount carrier in a vise or holding fixture. Lubricate pinion bearings with hypoid lubricant and install pinion in carrier. Install pinion bearing spacer with large end toward gear (use a new spacer). Install front pinion bearing cone and roller assembly on pinion shaft. Soak a new oil seal for 10 minutes in light engine oil. Wipe outer diameter of seal dry then coat outer diameter with Permatex No. 3. Install seal using J-5154. Install pinion flange and deflector assembly using tool J-5780 and J-2637-A. Install special washer and new self-locking nut. Tighten pinion flange nut, holding companion flange with tool J-2637-A. until torque required to keep pinion

CONTINUED ON NEXT PAGE

1955-60 CHEVROLET HYPOID (C ntinued)

rotating is 15 to 25 inch pounds (this may require a nut torque of as much as 350 ft. lbs. A torque wrench or a scale may be used to determine preload. A scale should read 1 7/8 to 3 1/8 pounds when applied at an 8" radius. *(CAUTION–When checking turning torque, mak sur that th re is no contact between deflector and carrier).* Install differential assembly in carrier and install outer races and adjusting nuts *(CAUTION–Carefully slid adjusting nuts alongside bearing so that thr ads on nuts fit into threads in carrier).* Install bearing caps, aligning marks on cap with marks on carrier. Install and tighten capscrews snugly (these will be retightened after ring gear and pinion are adjusted). On Passenger models, lubricate hubs of differential side gears with hypoid lubricant and install them in differential case. Roll the two differential pinions into position and install pinion gear shaft and shaft lockscrew. On ½-ton trucks, the differential side gears and pinion gears are installed after installation of carrier in rear axle assembly, *see "Axle Shaft Replacement (½-Ton Truck)" above.*

Ring Gear & Pinion Adjustment: Loosen right hand adjusting nut and tighten left hand adjusting nut using wrench J-972 while turning ring gear. Tighten left hand nut until all lash is removed, then back off the left hand nut one notch to a locking position. Tighten right hand nut to force left hand bearing firmly into contact with left adjusting nut. Then loosen the right hand nut and again tighten snugly against the bearing *(NOTE–Nut will be snug against bearing when rollers b gin t mov when c ntact is mad).* Tighten right hand nut a minimum of **ne additi nal notch, to a maximum of tw notch s further** to a locking position. Mount a dial indicator on carrier and check backlash between ring gear and pinion. Backlash should be .005-.008" (1955-56), .003-.010" with .005-.008" preferred (1957-60). Correct by moving each adjusting nut an equal amount in the same direction to retain preload and change backlash. Tighten bearing cap bolts to 70-75 ft. lbs. Recheck backlash and install both adjusting nut locks.

Differential Carrier Installation: Clean out axle housing thoroughly and place new gasket over carrier mounting bolts. Assemble differential carrier assembly to axle housing, install new copper washers and nuts and tighten securely. Connect rear universal joint.

CHEVROLET TRUCK HYPOID

Ch vr l t Truck ¾, 1, 1½, 2-Ton (1954-60)

►CHANGES, CAUTIONS, CORRECTIONS

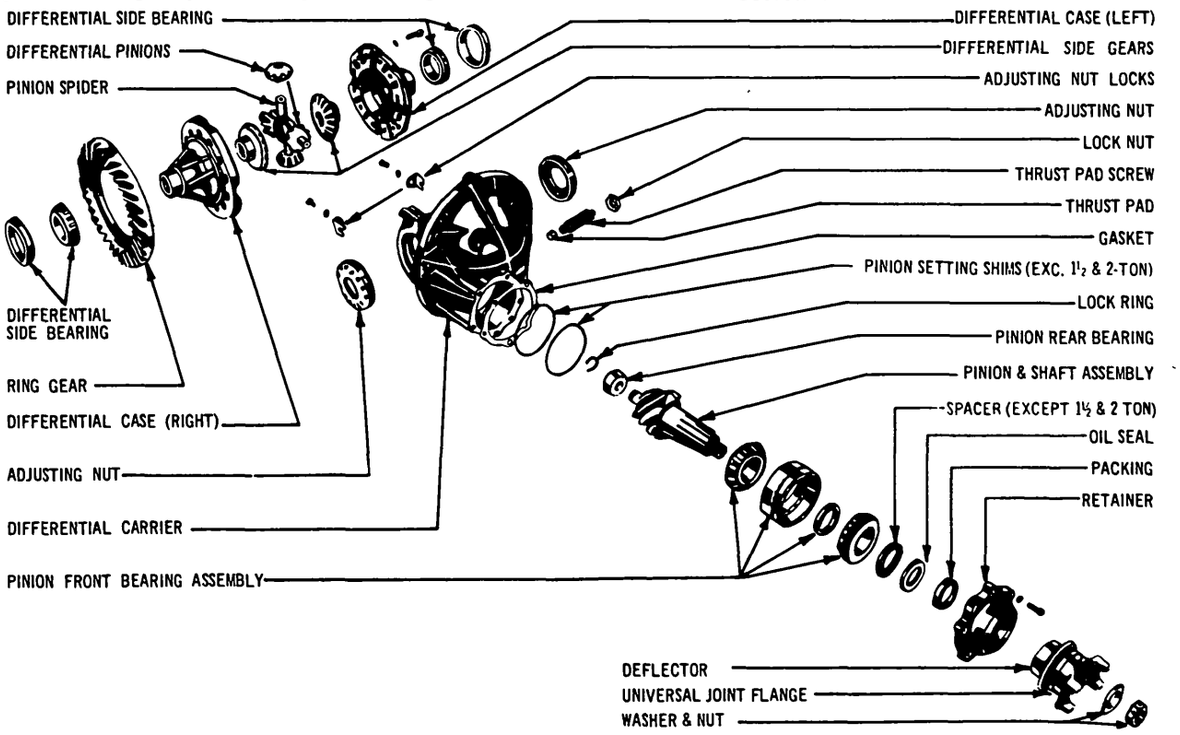
►*1960 2-TON TRUCK REAR END JACKING CAUTION:* When lifting these models at the rear with a hydraulic jack, the jack should be placed under the spring just forward of axle housing. *NOTE - This procedure supers d s pr vi us jacking procedures.*

DESCRIPTION: Full floating, hypoid gear type, with "straddle" mounted pinion shaft (rear end of pinion is supported in carrier housing on a roller bearing). ¾-ton, 1-ton & Heavy Duty 2-ton trucks have two tapered roller bearings (one piece outer race) on pinion shaft assembly. 1½-ton & Standard Duty 2-ton trucks have a double row ball bearing on pinion shaft assembly. ¾-ton & 1-ton trucks have flange type axle shafts bolted to wheel hub. Other models have a splined flange type axle shaft with splines fitting into splines in wheel hub.

DIFFERENTIAL CARRIER ASSEMBLY REMOVAL: *See "R ar Axl " on Truck M del pages.*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Truck M d l pag s.*

REAR WHEEL BEARING ADJUSTMENT: *See "Rear Axl " on Truck Mod l pages.*



DIFFERENTIAL CARRIER: Disassembly - Mount assembly in a bench vise, then loosen ring gear thrust pad lock nut and remove thrust pad. Remove differential adjusting nut locks and bearing cap bolts, then mark bearing caps and carrier for reassembly in the same position. Remove bearing caps and adjusting nuts by tapping on bosses of caps until free from dowels. *CAUTION - D n t us screwdriver to pry cap off as this may damag machined face of cap.* Remove differential and ring gear from carrier housing being careful that side bearing outer races are not dropped. Remove bolts attaching pinion bearing retainer to carrier, then remove pinion and bearing assembly from carrier. *NOTE - It may be necessary to drive this unit from carri r. Us a brass drift against pilot nd of pini n.* On ¾ & 1-ton trucks, remove shims from inside of carrier housing, making note of number and total thickness of shims removed. On 2-ton heavy duty models, drive the pinion rear bearing outer race and roller from carrier housing. *NOTE - On other models, this bearing will be removed with pinion shaft assembly.*

Pinion: Disassembly - On all models, clamp pinion drive flange in a bench vise and remove cotter pin, nut, and washer from end of pinion shaft. Remove drive flange and bearing retainer from shaft, then drive oil seal and packing from retainer. Proceed as follows:

¾-Ton & 1-Ton - Remove front spacer, front bearing, and center bearing spacer from shaft, then remove rear pinion bearing snap ring and press bearing from shaft with Tool J-2229 and an arbor press. Install Tool J-2224 (¾-Ton truck), J-2225 (1-Ton truck) over pinion teeth and press pinion bearing from shaft.

1½-Ton & Std. Duty 2-Ton - Remove rear pinion bearing snap ring and press pinion rear bearing from shaft with Tool J-1453 and an arbor press, then press off double row ball bearing assembly with Tool J-1439 or J-1440.

CONTINUED ON NEXT PAGE

CHEVROLET TRUCK REAR AXLE ASSEMBLY (TYPICAL)

CHEVROLET TRUCK HYPOID (C ntinued)

Hvy. Duty 2-Ton - Press off front pinion bearing assembly (opposed tapered rollers) with Tool J-6203 (6 tooth pinion), J-6171 (5 tooth pinion). Press inner race of rear pinion bearing off shaft with Tool J-0358 or J-1453.

Inspection - Wash all parts in solvent and blow dry with air. Inspect pinion for scored, cracked, chipped, or worn teeth. Inspect splines on pinion shaft for wear. Check pinion bearing assemblies for roughness, defects, or excessive wear.

Differential: Disassembly - Check differential case to make sure the two halves are marked so they may be reassembled in the same position, then remove bolts holding cover and case together. Separate cover from case and remove pinions, spider, and side gears. Remove ring gear from case by tapping back of gear with a soft hammer. Install Tool J-8107, making sure puller legs are securely in notches in case and tighten retaining yoke. Tighten puller screw to remove bearing. Remove bearing on opposite side in same manner.

Inspection - Wash all parts in solvent, then inspect ring gear for cracked, chipped or worn teeth. Inspect differential case and cover for scored side gear and pinion thrust surfaces. On 1½-ton trucks, inspect differential pinion gear and side gear thrust washers.

NOTE - Replace these thrust washers if even the slightest wear is indicated. Check radial clearance between differential side gears and differential case, and fit of pinions on spider. Inspect spider arms for wear and distortion. Inspect splines and teeth of differential side gears and pinions for chipping or excessive wear. Check differential side bearings and cups for broken races, discoloration or roughness. Inspect differential case for cracks or distortion.

DIFFERENTIAL CARRIER: Reassembly - With all parts clean and dry, proceed as follows:

Differential: Reassembly - Place a new bearing on hub with thick side of inner race toward case and drive bearing into position with Tool J-2226 (¾-Ton & 1-Ton), J-1488 (1½ Ton), J-6080 (2-Ton). Install two guide pins (made from capscrew with heads cut off and ends slotted) diametrically opposite to each other on ring gear. Start guide pins through case flange and tap ring gear into position on case. Lubricate differential side gears, pinions, and thrust washers (if so equipped), then place differential pinions (and thrust washers) on spider. Assemble side gears and pinions (and thrust washers) to left half of differential case. Assemble right half to left half being sure to line up the marks on both halves. Install ring gear bolts and lockwashers in ring gear and tighten evenly until ring gear is flush with case flange, then remove guide pins and install remaining two bolts. Tighten all bolts to 85-95 ft. lbs.

Pini n: R assembly - *NOTE - All pini n front b arings ar furnished as a compl t unit. On trucks with ta p red roll d type bearings, th bearing parts sh uld always be installed as a gr up as the bearing spac r is pres lect d to pr vide prop r pini n bearing adjustment.*

¾-T n & 1-T n - Press a new inner race and roller assembly on pinion shaft using a piece of 2" pipe and applying pressure against inner race (large diameter of bearing toward pinion gear), then place spacer and outer race on shaft and press other inner race and roller assembly on pinion (small diameter of bearing toward pinion gear). Lubricate bearing with engine oil. Lubricate rear pinion bearing and press on pinion, applying pressure to inner race. Install lock ring with Tool J-769. Soak a new oil seal and packing in engine oil, then install packing and oil seal in bearing retainer and press into position with Tool J-2231. *CAUTION - Make sure free side of leather in oil seal is toward pinion bearing.* Place pinion bearing retainer (with bolts and lockwashers installed) over hub of pinion drive flange, then install spacer on pinion and install drive flange, pinion bearing retainer, washer and nut to pinion.

1½-Ton & Std. Duty 2-Ton - Soak a new oil seal and packing in engine oil, then install felt packing in bottom of bearing retainer recess. Use Tool 2231 and press oil seal ring into retainer with seal lip toward pinion bearing. Install double row front pinion bearing assembly onto pinion shaft using a piece of 2" pipe to press against inner race until collar on inner race seats against pinion head. Press rear pinion bearing on pinion shaft until chamfered side of inner race seats against shoulder on pinion shaft. Slide oil seal retainer on pinion shaft and tap drive flange onto pinion splines. Clamp drive flange in a vise and install flange washer and nut. Tighten nut to 160-280 ft. lbs., then install cotter pin without backing off nut. Lubricate bearings with engine oil.

Hvy. Duty 2-Ton - Soak new oil seal and packing in engine oil, then install felt packing in bearing retainer recess and install oil seal with Tool J-6078 (lip of seal toward bearing). Press inner race of pinion rear bearing onto pinion shaft until it seats against shoulder on shaft. Press front pinion bearing assembly (opposed tapered rollers), including bearing spacer, onto shaft until it seats against head of pinion. If necessary to replace deflector on drive flange, use Tool J-6081 to drive deflector into position on flange. Slide pinion bearing retainer on pinion shaft, then tap drive flange onto pinion splines. Clamp drive flange in a vise and install flange washer and nut. Tighten nut until cotter pin can be inserted with nut tightened to 160-280 ft. lbs. Lubricate pinion bearings with engine oil.

Pinion: Installation (¾-Ton & 1-Ton) - *NOTE - If original ring gear and pinion are to be installed, replace same thickness of shims in carrier housing that were removed at disassembly. If a new ring gear and pinion are to be installed, use one .021" thick shim as standard starting setup, then after differential carrier is completely reassembled (ring gear and pinion adjusted), check and adjust pinion depth (see below).* Place shim pack in bore in carrier, then install a new gasket on bearing retainer and install pinion assembly in carrier. *NOTE - Carri r assembly should be pr ss d into carri r t prevent damaging shims.* Install bearing retainer bolts and lockwashers and tighten to 85-95 ft. lbs.

1½-Ton & 2-T n - On 2-ton trucks, drive pinion rear bearing outer race and roller assembly into place in carrier housing, then install pinion assembly in carrier housing, using a new gasket under retainer. *NOTE - Shims ar not r quir d f r pini n depth adjustm nt on these models as pinion d pth s tting will be correct when pinion assembly is prop rly install d.* Tighten pinion bearing retainer bolts to 160-170 ft. lbs. (1½ ton trucks), 90-100 ft. lbs. (2-ton trucks).

Differential: Installation - Lower differential assembly into carrier and install side bearing cups and adjusting nuts. *CAUTION - Carefully slid adjusting nuts alongside bearings so that threads on nut fit int thr ads in carrier.* Install differential bearing caps making sure that marks on cap line up with marks on carrier. Install bearing cap bolts and tighten until lockwashers just flatten out.

Ring Gear & Pinion Adjustm nt (Sid B aring Pr l ad & Gear Backlash): With differential bearing cap bolts loosened just enough to permit turning bearing adjusting nuts with Tool J-0972, remove all backlash between ring gear and pinion. Back off left hand adjusting nut one or two notches to a locking position, then tighten right hand nut firmly to force differential in solid contact with left hand adjusting nut. Back off right hand adjusting nut until free of bearing, then retighten snugly against bearing. Tighten right hand nut from one to two additional notches to a locking position. Mount a dial indicator on carrier and check backlash between ring gear and pinion which should be .003-.010" (.005-.008" preferred). If backlash is more than .010" loosen right hand adjusting nut one notch and tighten left hand nut one notch. If backlash is less than .003", loosen left hand nut one notch and tighten right hand nut one notch. Tighten bearing cap bolts to 95-105 ft. lbs. (¾-Ton & 1-Ton), 190-220 ft. lbs. (1½-Ton & 2-Ton). Recheck backlash and install both adjusting nut locks. Tighten attaching bolts to 11-18 ft. lbs.

Pinion Depth Checking & Adjusting (¾-T n & 1-T n): With differential installed and adjust (see above), coat ring gear teeth lightly with red lead or prussian blue, then turn pinion shaft several revolutions in both directions. Check the pattern on ring gear teeth. If pinion depth is correct, tooth pattern will be centered on pitch line and toward toe of ring gear. If pattern is below pitch line on ring gear teeth, pinion is too deep and it will be necessary to remove pinion assembly and increase shim thickness between pinion bearing and carrier. If pattern is above pitch line on ring gear teeth, pinion is too shallow and it will be necessary to remove pinion assembly and decrease shim thickness between pinion bearing and carrier. Shims are furnished in thicknesses of .012", .015", .018", .021". *NOTE - Changes in pinion depth will caus a chang in backlash which makes it nec ssary t readjust backlash.* Tighten bearing capscrews to 95-105 ft. lbs. Recheck backlash and install adjusting nut locks.

Ring Gear Thrust Pad Adjustm nt: Inspect bronze tip on ring gear thrust pad and replace if worn. Install thrust pad and tighten screw until bronze tip engages back of ring gear. Back off screw 1/12 turn and tighten locknut. *NOTE - This adjustment provid s .005-.007" clearanc betwe n pad and g ar.*

1954-55 CHEVROLET TRUCK 2-SPEED (DOUBLE REDUCTION) HYPOID

Ch vr l t Truck 1½ & 2-Ton (1954-55)①, Optional.

①—1955 1st Series Trucks only. "1955 Chevrolet Truck 2-Speed" used on 1955 2nd Series Trucks.

►**Axl Shaft Diff rential Side Gear Note**—Beginning with 1952 production, axle shaft and differential side gears have 27 splines and are interchangeable with axle shafts on 1952 Two-Ton Single Speed Axle.

►CHANGES & CORRECTIONS

►**REPLACEMENT REDUCTION GEAR INSTALLATION CAUTION:** Reduction gear mounting bolt holes in replacement differential case and cover are drilled undersize (35/64" drill) and must be reamed at assembly with a 9/16" reamer using the gear as a pilot. Ream one hole, then install bolt to hold gear and case or cover in correct position while reaming remaining holes. **When replacing reduction gear,** install all bolts which can be inserted without forcing, then ream remaining holes with 9/16" reamer, using gear holes as pilot for reamer.

DESCRIPTION: Hypoid Gear, double-reduction type with conventional first reduction hypoid ring and pinion gear and a second reduction consisting of two helical gears on the ring gear shaft (short separate shaft in front of differential case and axle shafts) which mesh with two larger gears on the differential case. These second reduction gears are constant-mesh type and one set at a time is engaged by the shifting sleeve on the ring gear shaft between the gears. Shifting sleeve locks the gear to the shaft and is actuated by the Vacuum Shift Control diaphragm as follows:

Vacuum Shift Control: Consists of a double-acting diaphragm type vacuum power cylinder mounted on axle carrier housing and linked directly to the double reduction gear shifter sleeve. Diaphragm pushrod is spring-loaded in the piston rod with spacers and stopwashers which limit pushrod travel. This enables the gear ratio to be "pre-selected" by movement of the selector valve on the instrument panel. When selector valve is moved to "Lo" or "Hi" range, a corresponding movement of the diaphragm and pushrod compresses the spring, and as soon as torque is relieved (by momentary letting up on accelerator pedal), the spring moves the piston rod and completes the shift. Shifting sleeve is centered in "Lo" and "Hi" positions by 3 spring-loaded poppet balls in the sleeve hub.

REMOVAL OF AXLE: ***See "Rear Axle" on car model page for removal of carrier assembly from truck.***

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Same as for full-floating truck axle. ***See "Chevrolet Truck Hypoid (Full-floating)" Rear Axle.***

BRAKE DRUM REPLACEMENT: Brake drum is held to hub by three slotted screws which can be removed and replaced with a screwdriver. Be sure to place soft paper gasket between hub and drum.

VACUUM SHIFT CONTROL: Following operations can be performed without disassembling rear axle:

Vacuum Cylinder Diaphragm Replacement: Disconnect hoses at fittings on vacuum cylinder. Remove bolts holding two cylinder halves together, lift off outer half. Remove outer nut on pushrod **while holding inner nut stationary with ½" wrench.** Remove diaphragm plates and diaphragm. Reassemble new diaphragm in same manner using Permatex around pushrod hole in diaphragm plates to insure a good seal at this point. Check shifting operation in "Lo" and "Hi" range after unit reassembled.

►***CAUTION—Do not transpose hose connections.***

Oil Seal Replacement: Dismantle vacuum cylinder and remove diaphragm (see above). Remove nuts and washers on two mounting studs, lift inner half of vacuum cylinder off axle housing, drive old oil seal out. Soak new seal in engine oil, coat outer diameter of seal with permatex and install in cylinder with free side of leather down (in), press seal in place with tool J-968. Install inner half of cylinder on axle housing, reassemble diaphragm.

Shifter Spring Replacement: Dismantle vacuum cylinder and remove diaphragm (see Diaphragm Replacement above). Press in on end of pushrod to relieve spring pressure, remove snap ring from inner rim of piston rod, withdraw pushrod assembly. Clamp head of pushrod bolt in vise, remove two nuts, short spacer, stop washer, spring, long spacer, and stop washer from pushrod bolt. Reinstall parts in same order using a new spring. Tighten adjusting nut on pushrod until distance between outer faces of stop washers is 3½", install and tighten locknut being careful not to change adjustment. Lubricate inside of piston rod with engine oil, install pushrod and replace snap ring. Reassemble vacuum control.

DIFFERENTIAL CARRIER DISASSEMBLY: Mark differential bearing caps and carrier to insure reassembly in same position. Remove adjusting nut locks, adjusting nuts, and bearing caps, lift differential assembly out of carrier. Remove nuts on pinion cage mounting studs, take out lubrication plug. Install two 3/8" bolts in tapped holes in pinion cage flange, turn nuts up evenly to remove cage assembly. **Note number and thickness of shims under carrier flange** (these shims control pinion mesh). Loosen locknut on bolt attaching shifter fork to vacuum control piston rod, remove bolt. Remove nuts on vacuum cylinder mounting studs, remove cylinder, piston rod, mounting sleeve and shims (tap on end of piston rod to free it from shifter fork). Remove nuts on double reduction shaft bearing caps, remove caps and shims (use two 3/8" capscrews in tapped holes in left bearing cap to remove cap), **note number and thickness of shims removed at each bearing cap** (these shims control ring-and-pinion gear backlash and bearing adjustment). Slide double reduction shaft assembly to left and pull ring gear end to rear to clear differential bearing support, remove shaft assembly. Remove right bearing outer race by driving race through into carrier with driver J-872-1. Do not remove left bearing race (race is pressed in bearing cap and these parts furnished as an assembly). Disassemble and service the major sub-assemblies as follows:

Pinion Cage Disassembly & Reassembly: Remove nut on end of pinion shaft, remove universal joint flange. Support carrier end of pinion cage in arbor press, press pinion and rear bearing out of cage, remove bearing spacer from pinion shaft. Press front bearing and oil seal out of cage. To remove bearing from pinion shaft, use Pinion Bearing Remover J-2228 to prevent damage to bearing while pressing shaft out. Use long drift to drive bearing outer races out of pinion cage. Install new races in cage using special driver J-5676 (front race), J-5677 (rear race). Lubricate all parts before re-installing, make certain that bearing spacer in place on shaft between bearings, install universal flange but **d not install oil seal** until after bearing pre-load adjusted, tighten pinion nut to 75-150 ft. lbs., check and adjust bearing pre-load as directed below. After pre-load adjusted, soak new oil seal in engine oil, install oil seal with driver J-971 with free edge of seal toward bearing. Re-install universal flange, install cotter pin (CAUTION—do not back nut off washer, and nut, tighten nut to 75-150 ft. lbs. and to align cotter pin hole, stop tightening the nut at point where slot lines up with hole).

Pinion Bearing Pre-load Adjustment—Check pre-load by clamping pinion cage flange in vise and using spring scale and rod to measure torque required to turn pinion (pinion nut must first be correctly tightened to 75-150 ft. lbs.). Turning torque should be **12-18 in. lbs.** (or 1-1½ ft. lbs.). Adjust by installing spacer or shims of correct thickness on shaft between bearings (thinner shims will increase turning torque, thicker shims decrease turning torque). These adjusting shims furnished in seven thicknesses as listed below and combinations of two shims will provide necessary range of adjustment from .316" to .354" in .002" steps.
Adjusting Shim Part Nos.—3847424—.157", 3847425—.159", 3847426—.163", 3847427—.167", 3847428—.171", 3847429—.175", 3847430—.177".

Double Reduction Shaft Disassembly & Reassembly: Remove capscrew and bearing retainer washer on each end of shaft, support tooth side of ring gear on hardwood blocks in arbor press, press shaft out of ring gear and bearing. Remove high speed pinion, shifter sleeve and poppet balls and springs (CAUTION—balls and springs will fly out as sleeve is removed). Replace sleeve on shaft with tapered side against pinion, support sleeve on hardwood blocks in arbor press, press shaft out of bearing, lift off bearing and low speed pinion. When reassembling, lubricate all parts for initial lubrication, install high speed pinion with clutch teeth toward splines on shaft, see that ring gear key in place in shaft, press shaft in gear until shoulder on shaft is against gear, press bearing on shaft against gear, install bearing

CONTINUED ON NEXT PAGE

1954-55 CHEVROLET TRUCK 2-SPEED (DOUBLE REDUCTION) HYPOID (C ntinued)

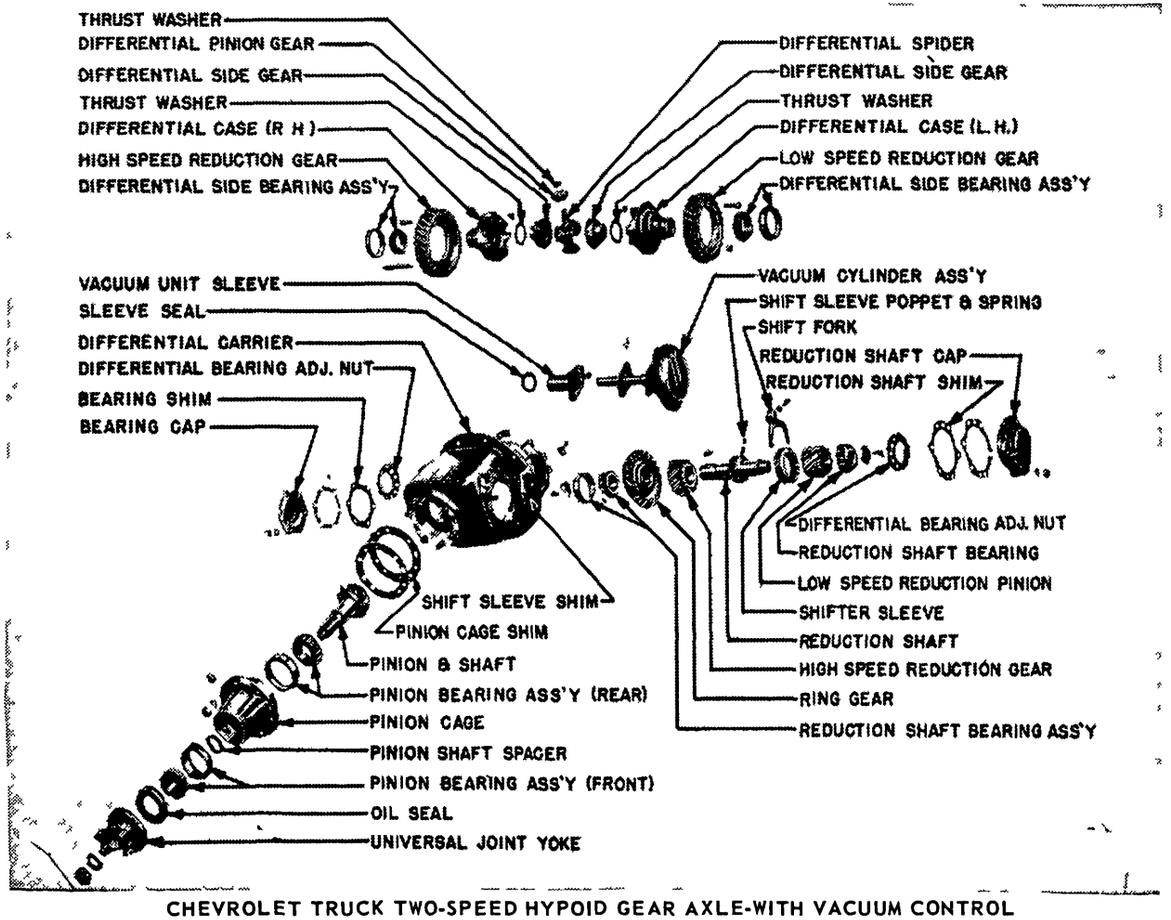
retainer washer and capscrews, tighten capscrews to 37-46 ft. lbs. and secure with lockwire. Install poppet springs and balls in shaft holes, install shifter sleeve on shaft with **heavy tapered end of sleeve toward ring gear and three tapered teeth on sleeve in line with poppet balls.** Install low speed pinion, press bearing on shaft firmly against shoulder, install bearing retainer washer and capscrews, tighten capscrews to 37-46 ft. lbs. and secure with lockwire.

Differential Disassembly & Reassembly: Mark halves of case to insure correct reassembly. Remove nuts on eight long through-bolts, separate differential case halves, remove differential side gears, pinions, and thrust washers To remove side bearing cone and roller assemblies, install J-1318 Differential Bearing Puller on bearing, support differential case in arbor press with bearing puller down, use drift inserted through case to press puller and bearing down off case hub Press new bearings on hub firmly against shoulder on case using J-1312 Bearing Replacer. **To replace double reduction gears, remove** gear mounting nuts and bolts, tap gear off case, make certain that mating flanges of case and new gear are clean and smooth, tap gear in place, tighten mounting bolt nuts evenly to 70-110 ft. lbs. and secure with lockwire

CAUTION—Double reduction gear mounting bolt nuts should be at inner face of differential case halves, nuts on long through-bolts should be on left side or AWAY from ring gear.

DIFFERENTIAL CARRIER REASSEMBLY: Reverse disassembly directions and make the following adjustments during the reassembly operations:

Double Reduction Shaft Bearing Adjustment: Install assembly with same thickness of shims under each bearing cap as were removed during disassembly (install left cap first, tighten mounting stud nuts securely). With correct bearing adjustment, shaft should rotate with slight drag (bearing pre-load only—pinion must be out so that no pinion drag added). Adjust by adding or removing shims at right or left bearing cap (shims will be transferred from one side to the other during ring-and-pinion gear backlash adjustment). **After backlash adjusted, tighten all bearing cap nuts to 75-95 ft. lbs.**



Ring-and-Pinion Gear Mesh (Pinion Setting Adjustment): Install pinion cage in carrier with same thickness of shims under cage flange as were removed during disassembly, install nuts on 3 equally spaced mounting studs and tighten nuts securely. Check gear mesh by painting ring gear teeth with red lead or Prussian blue, rotate pinion by hand in both directions while pressing on back of ring gear to apply a load. Make necessary adjustment of pinion position for correct mesh by adding shims (to move pinion out), or removing shims (to move pinion in) from beneath pinion cage flange. These shims furnished .003", .005" thick. After adjusting pinion position and backlash (see below), install all pinion cage mounting stud nuts and tighten evenly to 115-130 ft. lbs.

Ring-and-Pinion Gear Backlash: Check backlash with dial indicator mounted on carrier. Backlash should be .008-.013". Adjust by transferring shims from under one double reduction shaft bearing cap to the other keeping total shim thickness constant to avoid disturbing bearing adjustment (move shims from left to right side to increase backlash, from right to left side to decrease backlash). These shims furnished .003", .005" thick. After adjustments completed, tighten bearing cap nuts to 75-95 ft. lbs.

Two-speed Shifter Mechanism Installation: With shifter sleeve in low-speed position, install shifter fork in sleeve with lock bolt hole toward rear of carrier. Place rubber oil seal on vacuum unit mounting sleeve and install sleeve in carrier with same thickness of shims under sleeve flange as were removed when unit disassembled. Use new gasket on vacuum cylinder piston rod, insert rod and cylinder assembly in sleeve, enter end of rod in shifter fork and line up hole in rod and fork, install taper bolt and tighten locknut securely. Tighten cylinder mounting stud nuts. Check assembly as follows:

Shifter Mechanism Adjustment—With shifter sleeve in low-speed position, check clearance at each side of shifter fork with a feeler gauge. If clearance less than .010" at either side of fork, loosen vacuum cylinder mounting nuts, add or remove shims from under mounting sleeve flange (shims slotted, not necessary to remove cylinder or sleeve), tighten nuts and recheck shifter fork clearance.

Differential Bearing Adjustment: When installing differential assembly, assemble adjusting nuts and bearing caps in accordance with marks. Tighten bearing cap stud nuts just snug. Shift differential to right or left (by turning up one adjusting nut and backing off opposite nut) until double reduction gears and pinions are centered. Position one adjusting nut in a locking position (slot in line with lock tang), tighten opposite adjusting nut until all clearance or endplay just removed, then tighten each adjusting nut one additional notch for correct bearing pre-load. Tighten bearing cap stud nuts evenly to 150-170 ft. lbs., install adjusting nut locks, secure bearing cap nuts with lockwire.

CHEVROLET TRUCK TWO-SPEED HYPOID GEAR AXLE-WITH VACUUM CONTROL

1955-60 CHEVROLET TRUCK 2-SPEED (PLANETARY) HYPOID

1½-2-T n Trucks (1955 2nd Series - 1959)
2-T n Trucks (1960)

DESCRIPTION: Vacuum controlled 2-speed planetary-reduction type with hypoid primary gears and four planetary pinions. A five tooth and a six tooth drive pinion are used with a correct mating ring gear to furnish two different ratios.

OPERATION: In low range operation the primary (hypoid) reduction is multiplied by a planetary system reduction of approximately 1.36-1 for final drive. The secondary reduction occurs only when the sun gear is held stationary, the four planets then being driven around the sun gear by internal teeth in the large case bolted to the ring gear. Planet journals are integral with the planet support and the differential and planet support cover. The orbit speed of the planets is conveyed to rear wheels through cover, differential pinions, differential side gear and axle shafts. Control of the sleeved sun gear is through lateral movement of a coaxial "shifter sleeve" splined over the sun gear. Left hand movement of shift collar and sleeve causes sun gear to stop when dove-tail teeth in an anchor ring attached to housing engage similar teeth on approaching face of shifter sleeve. Right hand movement of shifter collar and sleeve by the vacuum control mechanism results in release from the anchor ring. Clutching teeth on opposite face of shifter sleeve then mesh with dove-tail teeth projecting from differential and planet support case and ring gear assembly. Thus engaged, the sun gear must turn at speed of ring gear, the planets are locked in place and only the reduction afforded by primary drive gears determine rear wheel speed. A positive, quick acting, two way vacuum system actuates the shift collar and sleeve. The hand control is located on the gear shift lever.

DIFFERENTIAL CARRIER ASSEMBLY: Removal–Drain rear axle housing and remove hub caps. Remove jaws from Sliding Hammer J-1436 (Rear Axle Shaft Bearing & Oil Seal Remover) and install adapter J-1436-8 to puller handle. Install axle shaft puller into hole provided in end of axle shaft and pull shaft (both sides) out about 8" to clear differential. Remove clamps and hose assembly at vacuum cylinder and slip hoses off fittings. Split rear universal joint by removing trunnion bearing "U" bolts from rear flange. Slide propeller shaft assembly forward and tape universal joint bearing to prevent bearings falling out. Swing propeller shaft to one side and tie it to frame side rail. Remove capscrews attaching differential planet and carrier to axle housing (*NOTE*–Before removing last capscrew, place a long drift punch through upper hole in assembly to give it support during removal). Place a roller jack under assembly using a wood block as necessary to support the unit. Work assembly forward until it clears housing, then remove it from under truck.

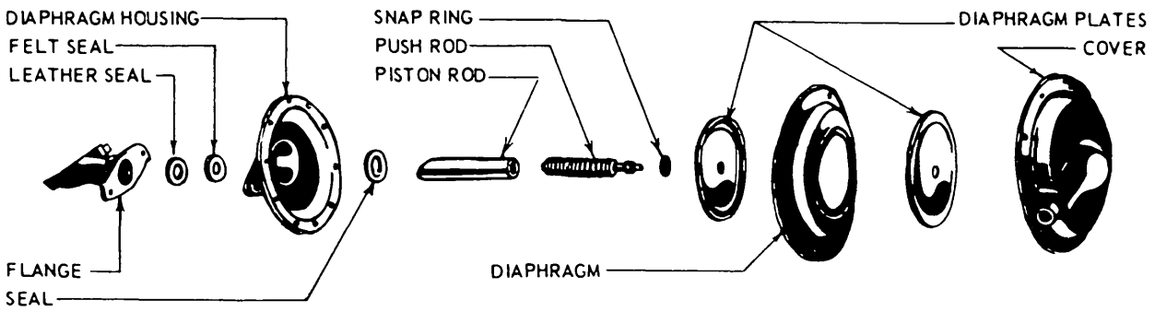
DIFFERENTIAL CARRIER ASSEMBLY: Disassembly–Proceed as indicated below

Vacuum Cylind r: R moval–Remove three bolts and lockwashers securing cylinder assembly to carrier housing and remove cylinder assembly.

Disass mbly–Remove two nuts and bolts retaining diaphragm housing to flange and separate housing from flange. Unscrew screws and self-locking nuts securing diaphragm cover to housing and separate cover and housing. Using two half inch open end wrenches, remove nut securing diaphragm plates and diaphragm to pushrod assembly. Separate plates and diaphragm. To disassemble pushrod assembly, compress spring of pushrod, remove snap ring from inside diameter of piston rod, and pull pushrod out of piston rod.

Differential & Planet Unit: Removal–Remove differential and planet assembly anchor from left side of assembly. Loosen locknut on ring gear thrust pad and remove pad. Drive out shifter yoke shaft using a drift punch and a hammer. Slide shifter yoke and sleeve to left and remove from end of sun gear. Remove retaining bolts and washers from adjusting nut locks and remove locks from both sides. To remove oil trough, bend tabs downward, remove two bolts and remove trough and locking plate. Remove bolts and lockwashers securing bearing caps and tap caps off dowels in mounting bosses with a soft hammer. Remove adjusting nuts. Lift differential and planet assembly out of carrier housing using extreme care not to drop side bearing outer races.

Disassembly–Mark ring gear, support case and case cover for alignment by scribing lines on case, cover and gear. Remove the twelve bolts retaining ring gear, case, and cover and lift off case assembly. Remove sun gear and planet gears (*CAUTION–Mark or tag all gears so they may be reassembled exactly as removed. If necessary to replace planet gears, the complete set of gears must be replaced).* Lift differential and planet support off case cover. Remove the eight bolts and lockwashers connecting planet support and cover and separate the two parts (*NOTE*–The support and cover are stamped on all four sides with matching numbers to aid in reassembly). Remove spider, pinion gear and thrust washers, and tag all parts as removed. Remove right and left hand side gears and thrust washers from each side of housing. Remove differential bearings from differential and planet support case and case cover.



Pinion Gear & Shaft Removal–Loosen bolts and lockwashers securing pinion assembly to differential carrier until bolt heads contact the universal joint flange. Gradually tap pinion assembly outward while loosening bolts to avoid interference with companion flange (*NOTE*–If universal joint flange is removed from pinion assembly, the pinion assembly can be removed by using adapter J-6187 with Slide Hammer J-1436). **Disassembly**–Remove shims from differential housing and note the amount used to assure reinstallation of the same number. Remove rear bearing from differential. Place universal joint flange in a vise and remove cotter pin, nut and flat washer securing flange to pinion and remove flange. Drive oil seal out of retainer housing and remove felt washer (discard oil seal). Press inner race off end of pinion using tool J-1453 and holder J-358-1 Using tool J-6171 (5 tooth pinion), or J-6079 (6 tooth pinion), press double thrust bearing off pinion with an arbor press.

DIFFERENTIAL CARRIER ASSEMBLY· Inspection, Reassembly & Installation–Proceed as follows

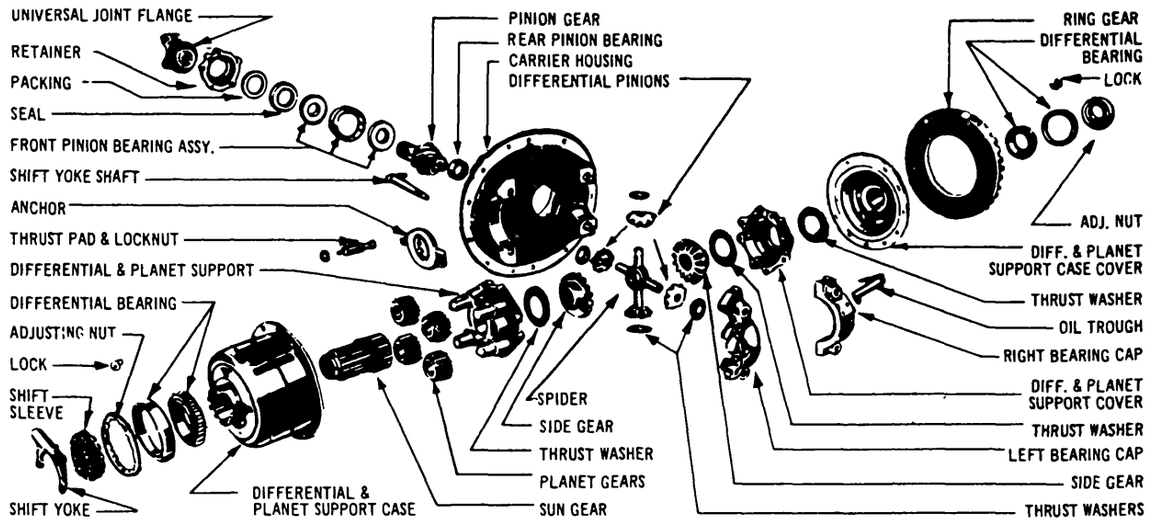
Pinion Gear & Shaft· Inspection–Wash all parts in solvent Examine pinion teeth for chips, cracks, and wear and check splines for wear Check thrust bearing for worn or pitted rollers or bearing race. Inspect universal joint flange for cracks or worn splines and examine oil seal retainer housing for cracks and defective sealing surface *NOTE*–If oil seal removed, replace with a new seal. Check rear bearing for worn or pitted rollers. Inspect oil deflector on universal joint flange for bends or other damage. Replace if necessary. **Reassembly**–Install inner race on end of pinion shaft. Lubricate and press double thrust bearing onto pinion shaft Install new felt washer and seal in pinion bearing oil seal retainer using Seal Installer J-6078 Place rear pinion bearing in differential carrier housing If oil deflector on universal joint flange requires replacement, tap off old deflector and install a new one, using Installer J-6081. Install oil seal retainer on pinion shaft. Insert a bolt and lockwasher through each hole in oil seal retainer and then position universal joint flange on pinion shaft With universal joint flange in a vise, install flat washer and nut on pinion and tighten to 180-250 ft lbs , and install cotter pin (*CAUTION–Do not back off nut to install cotter pin).*

Installation–Install rear pinion bearing in carrier housing and install same amount of shims as removed against shoulder in carrier housing (*NOTE–If new*

CONTINUED ON NEXT PAGE

CHEVROLET 2-SPEED AXLE SHIFT ASSEMBLY

1955-60 CHEVROLET TRUCK (PLANETARY) 2-SPEED (Cont.)



pinion and gear set to be installed, or old pinion requires resetting, see "Pinion Setting" below). Position pinion assembly in carrier housing and tap inward with a soft hammer until retaining bolts can be started in housing. Tighten retaining bolts to 85-95 ft. lbs.

Differential & Planet Unit: Inspection—Wash all parts in solvent (do not use air to dry bearings). Inspect ring gear, planet gears, differential pinion gears, and sun gear for damaged teeth or excessive wear. Inspect thrust washers for excessive wear. Inspect spider for wear or scored pinion bearing area. Inspect differential side gears and thrust washers for damaged teeth or excessive wear.

►*PARTS REPLACEMENT CAUTION:* If necessary to replace any single component in the following groups, all parts in each group must be replaced: (a) Sun gear and four planet gears. (b) Spider, four differential pinion gears, and thrust washers. (c) Ring gear and pinion. (d) Differential bearing and race.

Reassembly—Install differential bearings on differential and planet support case and case cover. Use Bearing Installer J-6080 to install bearing on case cover, and J-6175 to install bearing on case. Position side gear thrust washers on hubs of side gears and install one side gear in differential and planet support and one in differential and planet support cover *(NOTE—Gear with the longer hub is installed in the cover).* Assemble the four pinion gears and thrust washers on the spider, being sure to reinstall gears in their original positions. Install the assembled spider and gears in differential and planet support so that identification numbers on spider and planet support match. Lubricate gears and thrust washers with SAE 90 Multipurpose gear lubricant. Position support cover with matching identification marks aligned and install eight bolts and lockwashers. Tighten bolts to 70-110 ft. lbs. Install four planet gears on journals of differential and planet support *(CAUTION—Gears must be installed with radius on gears toward the planet support).* Mesh sun gear in planet gears. Place ring gear, teeth down on wood block and install four Guide Pins J-6154 in every third hole of the ring gear. With the assembly marks aligned, install differential and planet support case cover onto guide pins. Position support cover thrust washer on hub of side gear, then place planet assembly in differential and planet support case cover, with sun and planet gears upward. Install planet support case over guide pins, making sure that alignment marks are in line, and loosely install eight of the twelve retaining bolts. Remove guide pins and install the other four bolts. Tighten all bolts in rotation to 85-95 ft. lbs.

Installation—Position differential side bearing outer races on differential bearings and place differential and planet assembly in bosses of differential carrier housing. Install left and right adjusting nuts. Tap bearing caps onto dowels in bosses of differential carrier housing and then secure with bolts and lockwashers. Tighten bolts until lockwashers just flattened *(CAUTION—Bolts will be retightened to correct torque after backlash and pinion setting is checked and adjusted).*

CHEVROLET TRUCK 2-SPEED REAR AXLE

Backlash Adjustment—Loosen right hand adjusting nut and tighten left hand nut, Use Differential Adjusting Wrench J-972 on the right side and a drift and hammer on the left side. *(NOTE—Left side nut has internal notched teeth so that adjusting wrench cannot be used).* Continue tightening left hand nut until all backlash is removed between pinion and ring gear. Back off left hand nut approximately 2 notches to a point where notch in nut is aligned with lock. Tighten right hand nut firmly to force differential and planet assembly in solid contact with left hand nut. Loosen right hand nut until it is free of its bearing, then tighten nut snugly against bearing. **Tighten right hand nut from one to 2 notches more** to a point where notch in nut aligns with lock *(NOTE—This procedure provides for proper preload on bearings).* Mount a dial indicator on housing so indicator button contacts tooth on ring gear, and check ring gear backlash. Backlash should be .005-.008". If backlash greater than .008", loosen right hand adjusting nut one notch and tighten left hand nut one notch. If backlash less than .005", loosen left hand nut one notch and tighten right nut one notch. Check and adjust pinion setting as indicated below.

Pinion Setting—Coat ring gear teeth lightly with red lead or Prussian blue, then turn the pinion shaft several revolutions in both directions to establish a gear pattern on the ring gear. Examine pattern on the right gear teeth. If pinion depth is correct, the tooth pattern will be centered on the pitch line and toward toe of ring gear. If pattern is below pitch line on ring gear teeth, the pinion is too deep and it will be necessary to remove pinion and increase the shim thickness between pinion bearing and differential carrier housing. If pattern is above the pitch line, the pinion is too shallow and it will be necessary to decrease shim thickness in carrier housing. *NOTE—Changing the pinion depth will make some change in backlash and it may be necessary to readjust the backlash (see above).* Tighten bearing capscrews to 130-160 ft. lbs. Recheck backlash and install adjusting nut locks.

Thrust Pad Adjustment: Check bronze tip on thrust pad and replace if worn. Install thrust pad and tighten until pad contacts ring gear, then back off 30° to obtain a clearance of .005-.007". Tighten locknut.

Vacuum Cylinder: Inspection—Clean all metal parts with solvent and blow dry with air. Inspect diaphragm for loss of resiliency and punctures. Check spring of pushrod for breaks or distortion. Check mating surfaces of diaphragm housing and cover by placing the two parts in their assembled position and checking for deformation or burrs. Inspect piston rod outer surfaces for burrs as these can cause leaks at leather and felt seals.

Reassembly—Insert pushrod in piston rod and compress rod spring and install snap ring. Apply Permatex to ridges and around the center hole of diaphragm plates. Position diaphragm between the two plates and install plates and diaphragm on pushrod assembly. Install a new oil seal in diaphragm housing using Seal Installer J-968 (soak seal in oil prior to installation and coat outer radius with Permatex to assure a tight seal). Oil and install new leather and felt seals in diaphragm attaching flange. Insert pushrod assembly with attached diaphragm into housing. Align holes in diaphragm and housing and install housing cover.

Installation—Install vacuum cylinder assembly on differential carrier housing with three bolts and lockwashers.

COMET & FALCON HYPOID

Comet (1960)
Falcon (1960)

►CHANGES, CAUTIONS, CORRECTIONS

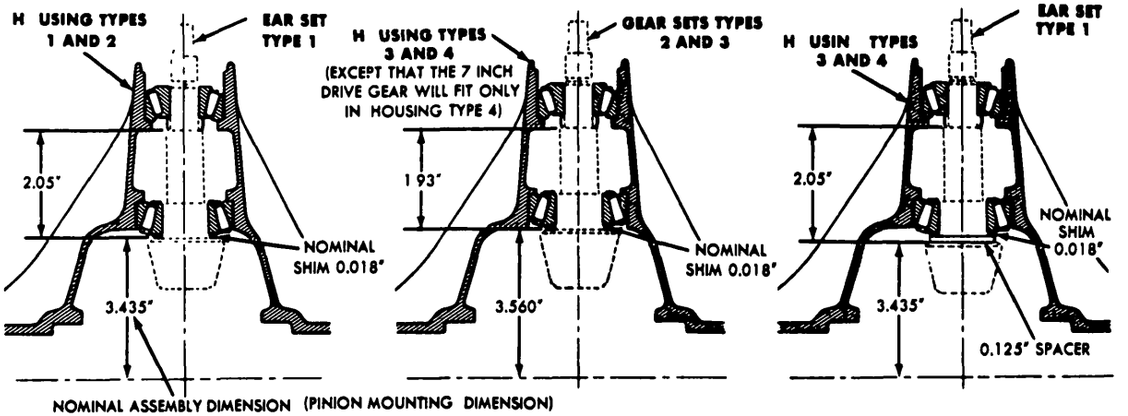
►*1960 REAR AXLE PRODUCTION CHANGES, PARTS REPLACEMENT, ADJUSTMENT & OVERHAUL CAUTIONS: Four different rear axle housings have been used in production. For identification, parts replacement, overhaul and adjustment, see "Overhaul" below.*

►*REAR AXLE CODE NUMBERS:* A production date code is stamped in 3/16" high characters on front of left hand axle shaft tube about three inches inboard from spring pad. The first digit indicates year (0-1960); the letter designates the month (C-March), and the last digit or digits designates day of month. *NOTE - On some very early Falcon models, a three character date code having three characters was used. The first character indicated year; second indicated month; and the third indicated week of month.*

►*PINION BEARING PRELOAD CAUTION:* Rear universal joint companion flange nut controls pinion bearing preload (must be adjusted whenever nut is loosened).

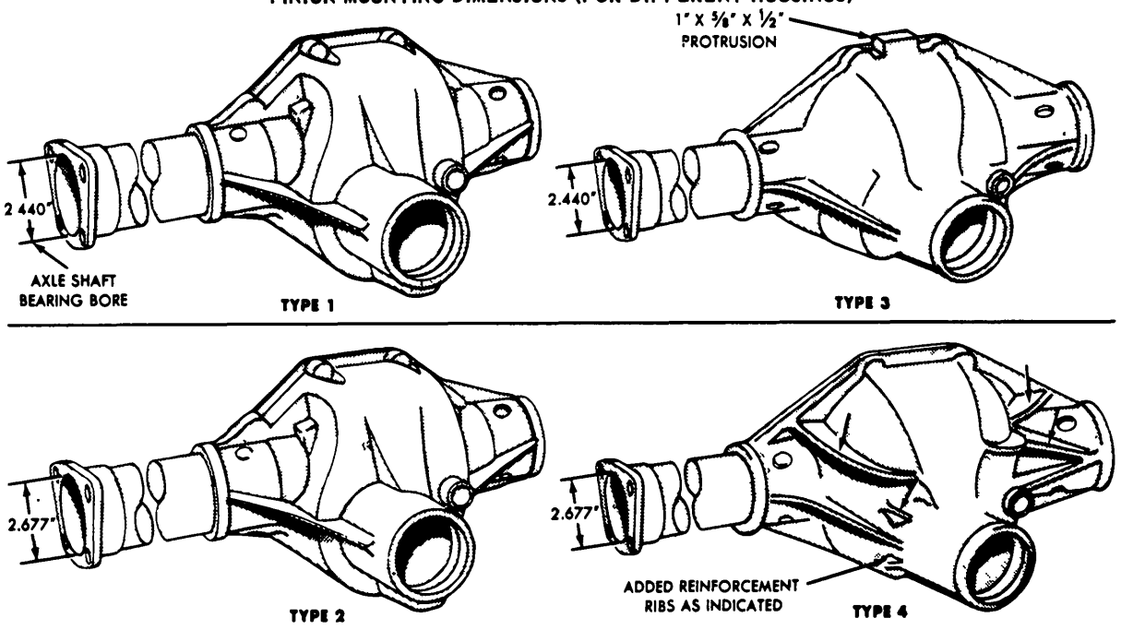
DESCRIPTION: Semi-floating, hypoid gear type with an integral type housing and Hotchkiss drive.

AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model pages.*



AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Model pages.*

REAR WHEEL BEARING REPLACEMENT: With axle shaft removed from housing, nick bearing retainer in several places with a cold chisel and remove retainer. Press bearing off of shaft using a suitable tool and an arbor press. To install bearing, use a suitable tool and press bearing into position with an arbor press, then press bearing retainer on shaft until it seats against bearing. *CAUTION - Do Not attempt to press bearing and retainer on shaft at the same time.*



AXLE SHAFT OIL SEAL REPLACEMENT: Remove axle shaft and remove seal from axle housing with a suitable tool (slide hammer). Coat outside edges of new seal with oil resistant sealing compound and install seal in housing with Tool 1177-B making certain that seal is against shoulder and with sealing lips toward differential assembly.

PINION OIL SEAL REPLACEMENT: Drain rear axle lubricant with a siphon, then disconnect drive shaft from drive pinion flange. Mark pinion shaft, end of pinion shaft, and pinion flange splines for realignment purposes. Hold flange with Tool 4851-K (Comet), T57L-4851-A (Falcon) and remove pinion shaft nut and flat washer. Remove pinion flange with Tool 4851-A and 4221-AL and remove pinion oil seal. Clean the oil seal seat and make sure that seal lubricant return passage is clear. Coat outer edge of new seal with oil resistant sealer and install seal with Tool 4676-G (Comet), T55P-4676-A (Falcon). Align pinion flange mark with pinion shaft spline mark and install flange. Install flat washer and pinion shaft nut, then slowly tighten nut until marks are aligned. *CAUTION - Alignment marks made at disassembly must be aligned properly to assure proper pinion bearing preload.* Connect drive shaft and fill rear axle housing with lubricant.

►*REAR AXLE OVERHAUL CAUTION: Four different rear axle housings and three different pinion and drive gear sets have been used in production as indicated below (see illustrations). It is important that housing and gear sets be properly identified before overhaul, parts replacement, or adjustment. See "Rear Axle Code Numbers" above for production codes and note the following:*

PINION MOUNTING DIMENSIONS (FOR DIFFERENT HOUSINGS)

REAR AXLE HOUSING TYPES

Type "1" Housing - *NOTE - This housing used on 2-Dr. and 4-Dr. sedans and has a production code number "OB20" or earlier.* Axle shaft tube ends are machined for 2.4" diameter wheel bearings and the housing is machined to locate "Type 1" gear set at 3.435" nominal pinion mounting dimension. *CAUTION - "Type 2" and "Type 3" gear sets CANNOT be used in this housing.*

Type "2" Housing - *NOTE - This housing used on Taxicabs, Rancheros, and Station Wagons and has a production code number "OB20" or earlier.* Axle shaft tube ends are machined for 2.6" diameter wheel bearings and the housing is machined to locate "Type 1" gear set at 3.435" nominal pinion mounting dimension. *CAUTION - "Type 2" and "Type 3" gear sets CANNOT be used in this housing.*

Type "3" Housing - *NOTE - This housing used on 2-Dr. and 4-Dr. sedans and has a production code number "OB22" or later.* Axle shaft tube ends are machined for 2.4" diameter wheel bearings and the housing is machined to locate "Type 2" gear set at 3.560" nominal pinion mounting dimension. *NOTE - "Type 1" gear set may be used in this housing by using a 1/8" spacer, Part No. CODW-4663-BB and the correct amount of pinion locating shims. "Type 3" gear set CANNOT be used in this housing.*

CONTINUED ON NEXT PAGE

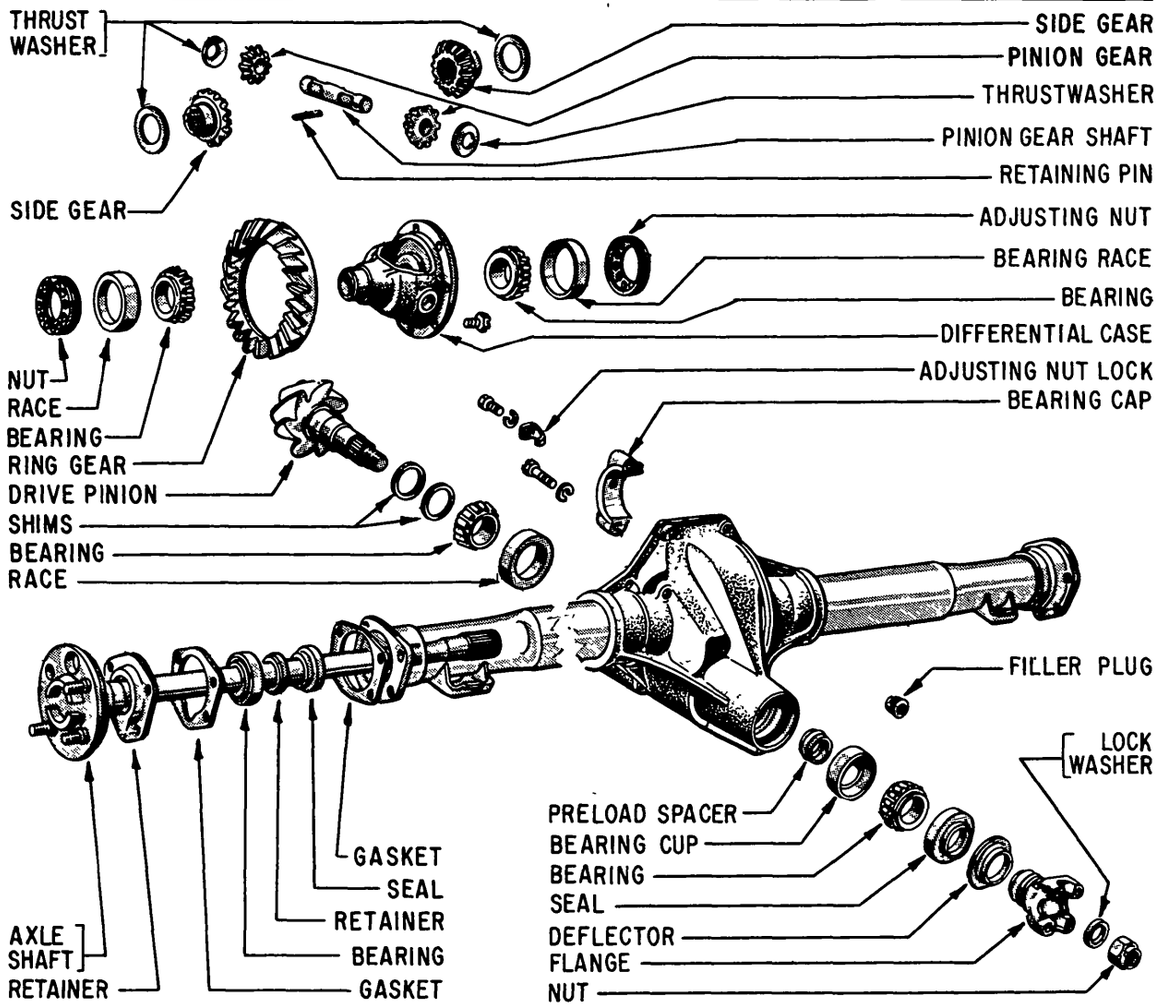
COMET & FALCON HYPOID (C ntinued)

Type "4" Housing - *NOTE - This housing is used on Taxicabs, Rancheros, and Station Wagons and has a production code number "OB22" or later.* Axle shaft tubes are machined for 2.6" diameter wheel bearings and the housing is machined to locate "Type 3" gear set at 3.560" nominal pinion mounting dimension. *NOTE - A 7" ring gear is used in this housing.*

Type "1" Gear Set - *NOTE - Used in all rear axles housings having a production code number "OB20" or arlier.* Identified by a 6¾" ring gear and a 2.05" dimension between rear bearing perch and preload spacer shoulder on pinion shaft. Pinion gear thickness is 1.57" (see illustration). *NOTE - This gear set may be found in Type "3" and "4" housings with a 1/8" spacer installed along with regular shims under pinion bearing cone.*

Type "2" Gear Set - *NOTE - Used in 2-Dr. and 4-Dr. sedan rear axle housings having a production code number "OB22" or later.* Identified by a 6¾" ring gear and a 1.93" dimension between pinion rear bearing perch and preload spacer shoulder on pinion shaft. Pinion gear thickness is 1.69" (see illustration). *NOTE - This gear set can be installed in Type "3" and "4" housings only.*

Type "3" Gear Sets - *NOTE - Used in Taxicab, Ranchero, and Station Wagon rear axle housings having a production code number "OB22" or later.* Identified by a 7" ring gear and a 1.93" dimension between pinion rear bearing perch and preload spacer shoulder on pinion shaft. Pinion gear thickness is 1.69". *NOTE - This gear set can be installed in Type "4" housings only.*



►*DIFFERENTIAL CASE PRODUCTION CHANGE & PARTS REPLACEMENT CAUTION: Two differential cases have been used in production as indicated below. Except for side gear thrust washers, none of the parts are interchangeable between the two cases.*

"Two-Window" Case - *NOTE - This type case used in all early 2-Dr. and 4-Dr. sedans and in some early Taxicabs, Rancheros, and Station Wagons.* On axle assemblies having a production code "OB22" or later, the "two-window" case is used with 3.10-1 ratio only. For identification, differential pinion gears are .640" thick and side gears are 1.040" thick. Differential pinion gear thrust washers are phosphate coated (black).

"One-Window" Case - *NOTE - This type case used in all rear axle assemblies, except 3.10-1 ratio, having a production code "OB22" or later.* For identification, differential pinion gears are .740" thick and side gears are 1.090" thick. Differential pinion gear thrust washers are cadmium plated (white).

►*PINION LOCATING SHIM PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* Beginning with axle assemblies having a production code "OB22" or later, larger (same inside diameter, larger outside diameter) pinion locating shims are used. These new shims are furnished for service replacement in thicknesses of .008"to .024" in steps of .001" and are interchangeable with the previous shims.

►*GEAR TOOTH CONTACT PATTERN CHANGE:* 3.10-1 ratio rear axle assemblies having a production code "OB20" or earlier ("Type 1" Housing) have a different gear tooth pattern than other assemblies. S e *"Pini n S tting" and "Backlash Adjustm nt" below.*

COMET & FALCON REAR AXLE ASSEMBLY

DIFFERENTIAL & DRIVE PINION INSPECTION (BEFORE DISASSEMBLY): Before disassembling rear axle, check backlash of drive gears and tooth contact pattern (see below). Note and record the necessary correction to be made in shim pack at reassembly to provide the correct gear tooth pattern.

DIFFERENTIAL CASE: *See "Differential Case Production change & Parts Replacement Caution" above.*

Removal: Mark one differential bearing cap and the case to insure installation at same location, then remove bearing adjusting lock nuts. Remove bearing cap bolts and caps and remove differential case and bearing cups.

Disassembly: Remove differential side bearings from case with Tools 4851-A and 4221-AL (Comet); T56L-400-A (Falcon). Remove bolts attaching ring gear to case and press or tap gear from case. Drive out differential pinion shaft retaining pin with a drift punch and drive out differential pinion shaft. Remove gears and thrust washers.

Inspection: *See "Inspection (General)" below.*

Reassembly: Lubricate all parts with rear axle lubricant before installation, then place side gears and thrust washers in case. Place two pinion gears and thrust washers exactly opposite each other in case opening (or openings) and in mesh with side gears. Turn pinions and thrust washers until holes in pinion align with pinion shaft holes in case and start pinion shaft into case. Align shaft retaining pin hole with pin hole in case, then drive shaft into place and install retaining pin. Place drive gear on case and tighten bolts to 35-45 ft. lbs. Press differential side bearings onto case with Tools 4222-L (Comet); T58P-6019-A (Falcon).

Installation: With drive pinion shaft installed in rear axle housing and properly adjusted for depth (see below), place cups on differential side bearings and set case assembly in axle housing so a slight amount of backlash is felt between gear teeth. Hold differential

CONTINUED ON NEXT PAGE

COMET & FALCON HYPOID (Continued)

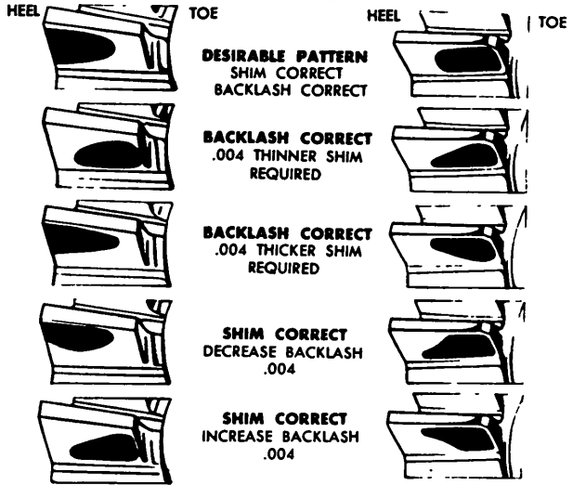
case in place and install adjusting nuts in bores so they just contact bearing cups. Carefully position bearing caps on carrier casting, aligning marks made at disassembly, then install bearing cap bolts and lock washers. As bolts are tightened, turn adjusting nut with Tool 4067-E (Comet); T60K-4067-A (Falcon). *CAUTION - If adjusting nuts do not turn freely as cap bolts are tightened, remove bearing caps and inspect for damaged threads or incorrectly positioned caps.* Tighten bolts to 30-40 ft. lbs., then adjust ring gear backlash *(see "Backlash Adjustment" below).*

PINION SHAFT: With differential case removed from rear axle housing (see above), proceed as follows:

Removal & Disassembly: Hold drive pinion flange with Tool 4851-K (Comet); T57L-4851-A (Falcon) and remove pinion nut and flat washer. Remove pinion flange with Tools 4851-A and 4221-AL (Comet); T53T-4851-K (Falcon). Drive pinion shaft out of front bearing cone with a soft faced hammer and remove it through rear of housing. Install rear axle housing in an arbor press and remove pinion shaft bearing cups with Tools 4625-L and 4615-G (Comet); drive out with a drift punch (Falcon). Remove pinion rear bearing cone with Tool 4625-F (Comet); T57L-4621-A (Falcon). Remove and measure pinion locating shims from between rear bearing cone and pinion gear.

Reassembly & Installation: Place differential housing in an arbor press and press a new rear bearing cup into housing with Tool 4625-HR (Comet); and a new front bearing into housing with Tool 4615-HF (Comet). On Falcon, install both front and rear cups at the same time with Tool T60K-4616-A. Place selected pinion setting shim pack *(see "Pinion Setting" below)* and bearing cone on pinion shaft and press bearing and shims firmly against pinion shaft shoulder with Tool 6306-AG-3 (Comet); T58P-6019-A (Falcon), then lubricate bearing with rear axle lubricant and place a NEW pinion bearing spacer on pinion shaft. Lubricate pinion front bearing cone and place it in housing, then install a new oil seal in housing *(see "Pinion Oil Seal Replacement" above).* Insert drive pinion shaft flange into seal and hold it firmly against pinion front bearing cone. From rear of housing, insert pinion shaft assembly through front bearing cone and into flange. Install flat washer and start nut on pinion shaft. Hold flange with Tool 4851-K (Comet); T57L-4851-A (Falcon) and tighten pinion shaft nut, pulling pinion shaft into front bearing cone and flange until the flange and cone are felt to "bottom" (indicating these parts are in contact with preload spacer). Complete pinion shaft installation by adjusting pinion bearing preload *(see "Pinion Bearing Preload" below).*

PINION BEARING PRELOAD: Tighten pinion shaft nut very slowly to a minimum torque of 140 ft. lbs. During the tightening operation check pinion bearing preload with Tools 4209-C and 4209-C-12 (Comet); 4858-N and 4610-N (Falcon) so that preload does not exceed the limits of 10-16 inch pounds (used bearings), 17-27 inch pounds (new bearings) torque required to rotate pinion shaft. *CAUTION - If pinion bearing shaft nut is tightened to the point that bearing preload exceeds limit, remove pinion shaft and install a new collapsible spacer. DO NOT decrease preload by loosening nut.* If correct preload is not obtained with a minimum torque of 140 ft. lbs., continue tightening nut slowly (checking preload frequently) until preload is within limits.



PINION SETTING: *See "Pinion Locating Shim Production Changes & Service Replacement Note" above.* To select correct shim thickness required for installation of a new pinion gear, measure thickness of original shim pack with a micrometer and note the reading. Note shim adjustment number on both old and new pinion (etched in end of pinion gear), then refer to shim table and note the amount of change shown in table under "New Pinion Marking" and in line with "Old Pinion Marking". Add or subtract the reading obtained from that of the original shim pack and record shim pack thickness. To the total shim pack thickness, add or subtract the shim correction indicated during gear tooth contact pattern check. The final result is the shim thickness required for installation of new pinion.

BACKLASH CHECK AND ADJUSTMENT: To check backlash, install dial indicator on rear axle housing so indicator contact is against gear tooth (parallel to ring gear) and check backlash at several points around ring gear. Backlash should be .008-.012". *NOTE - This dimension supersedes previous specifications.* If not within these limits, adjust as follows: Loosen bearing cap bolts and retighten to 5 ft. lbs., then loosen right hand adjusting nut (pinion side of ring gear) until it is away from cup. Tighten left hand nut until ring gear is just forced into pinion with no backlash. *CAUTION - Recheck right hand nut to make sure it is still loose.* Tighten right hand nut two notches past point where it contacts bearing cup, then rotate ring gear several times in each direction to seat bearings in cups. Again loosen right hand nut to release preload. If there is any backlash between gears, tighten left hand nut just enough to remove this backlash, then loosen left hand nut 1-1½ notches. *NOTE - At this time, make sure that one of the slots in left hand nut is located so lock can be installed without turning nut.* Tighten right hand nut until it just contacts bearing cup, then set bearing preload of 2½-3 notches tight by right hand nut to obtain a preload of .008-.012". Tighten bearing cap bolts

COMET & FALCON HYPOID (C ntinu d)

to 30-40 ft. lbs. and recheck backlash. If measurements taken at several points around ring gear vary more than .002", there is excessive runout which must be corrected. If backlash is not within specifications, loosen one adjusting nut and tighten opposite nut an equal amount. *CAUTION - When moving adjusting nuts, the final movement should always be made in a tightening direction.*

GEAR TOOTH CONTACT PATTERN: Paint gear teeth with a suitable gear marking compound (dry red lead and oil), then wrap a cloth around drive pinion flange to act as a brake and rotate ring gear back and forth until gear tooth contact pattern is obtained. Refer to "Gear Tooth Contact Pattern" illustration, and correct as indicated.

INSPECTION (GENERAL): Wash all parts in solvent and blow dry with air, then oil bearings to prevent rusting. Inspect teeth and thrust surfaces of differential gears. Check for wear on hubs of side gears, splines and thrust washers. Inspect bearing cups for score, galling, or erratic wear patterns. Examine roller ends for wear. *NOTE - "Step-Wear" on roller ends indicates bearings were not pr l ad d pr perly or roll rs w re slightly misaligned.* Temporarily install bearing caps in their respective positions and test fit adjusting nuts in their threads. Faces of nuts that contact bearing cups must be smooth and square. Polish these with a fine abrasive on a flat surface. If adjusting nut fit is not correct, replace nuts or examine threads in carrier. Check drive pinion flange to make sure ears of flange are not damaged. End of flange contacting bearing cone must be smooth (polish if necessary). Check differential case hubs and make sure bearings will seat firmly on hubs. Check fit of differential side gear hubs in case.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "CAGE" TYPE HYPOID

Chrysler Six (1954) Ⓒ
Chrysler V8 (1957-60)
DeSoto Six (1954-55) Ⓒ
DeSoto V8 (1956-60) Ⓒ
Dodge Six (1954-60) Ⓒ
Dodge V8 (1954-60) Ⓒ
Plymouth Six & V8 (1954-60)

Ⓒ - "Barrel" type used on some models (1954-56). *See "Chrysler, DeSoto, Dodge Barrel Type" Rear Axle.*

►CHANGES, CAUTIONS, CORRECTIONS

►*RING & PINION GEAR CAUTION:* Both "Formate" and "Generated" type gears used. Both types of gears are **interchangeable in matched sets only.** Gears can be identified by part number (stamped on all gears) or by word "FORMATE" stamped on all formate gears and pinions. Gears and pinions of "Generated" type have part number only.

►*CAUTION: Ring and pinion gears should be installed as matched sets and both gears must be of same type (Formate or Generated).*

►*1956 REAR WHEEL BEARING GREASE PLUG DISCONTINUED:* Bearings are packed at factory and additional lubrication is not required. If bearings are removed for any reason, they should be cleaned and repacked for reassembly.

►*1957 LUBRICANT LEVEL CAUTION (ALL MODELS):* DO NOT fill rear axle housing to level of filler plug opening. *See individual Car Model pages for correct quantity and lubricant level recommendations.*

►*1957 DRIVE PINION SHAFT NOTE:* Drive pinions used on Chrysler New Yorker & Imperial Models (Exc. Town & Country) do not have a bearing spacer. Front bearing and pinion preload shims bear directly on shoulder on shaft.

►*1959-EARLY 1960 REAR AXLE KNOCKING OR CHUCKLING NOISE CORRECTION:* A noise occurring at a steady 25-35 MPH or on slight deceleration with axle at normal operating temperature may be caused by excessive differential side gear-to-carrier housing counterbore clearance. If clearance is greater than .002" between side gear pilot journal and counterbore in case, install special side gear, Part No. 2070150 (this part number is not indicated in MoPar Parts Catalog). *NOTE - Later cars with selective fit differential case and gears have a yellow and green paint marking on carrier.*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss Drive. Power-Lock Differential, Optl.

AXLE SHAFT REPLACEMENT & ENDPLAY ADJUSTMENT: Release brake cams and remove rear hub and drum assemblies with Puller C-675 or C-845. *NOTE-DO NOT attempt to remove brake drum by hammering on end of axle shaft as damage to bearings and thrust block will result.* Disconnect brake line at each wheel cylinder. On 1954-56 models, take out stud nuts and remove oil seal and backing plate. On 1957-60 models, remove brake support plates and dust shields as an assembly. On 1954-56 models, remove and save bearing adjusting shims. Use Puller C-499 to remove axle shaft and bearing, Puller C-293-C to remove bearing from axle shaft. On 1957-58 models, remove axle keys, install Tool C-745 to protect outer seal, remove shims, axle shafts and bearing cups, then remove inner seals. On all models, clean all parts and check bearing and seal surfaces for wear. To install reverse removal procedure, then adjust axle shaft endplay.

Endplay Adjustment - Remove wheels and hubs, place dial indicator on axle shaft and housing. Pull shaft out and zero dial indicator. Push shaft in and note reading. Endplay should be .003-.008" (1954-56), .013-.018" (1957-60). To correct endplay, remove support plate and add or remove shims located on end of housing. *NOTE* - When necessary to remove more than .020" shims to correct endplay, remove half the amount from each end of housing.

Centering Axle Shafts (Axl Shaft R plac m nt) - Install left axle shaft and bearing (less grease). Use Tool C-413 (to protect housing) and drive bearing cup in as far as it will go. Spacer block will be to full right. Lay straightedge across end of housing, measure distance from straightedge to cup face. A shim pack equal to this measurement less 1/8" centers block. Use shim pack .010" or .020" less than required to center block. Remove left axle assembly, grease bearing and reinstall assembly with bearing cup, shims, and support plate. Repeat operation with right axle shaft assembly, except use straightedge across outer face of cup (cup will extend beyond housing). Use feeler gauges to measure distance between housing face and straightedge. Use shim pack equal to this measurement plus .003" (1954-56), .013" (1957-60), for right axle shaft. Remove right axle shaft assembly, grease bearing, and reinstall assembly with bearing cup, shims (determined above), and support plate.

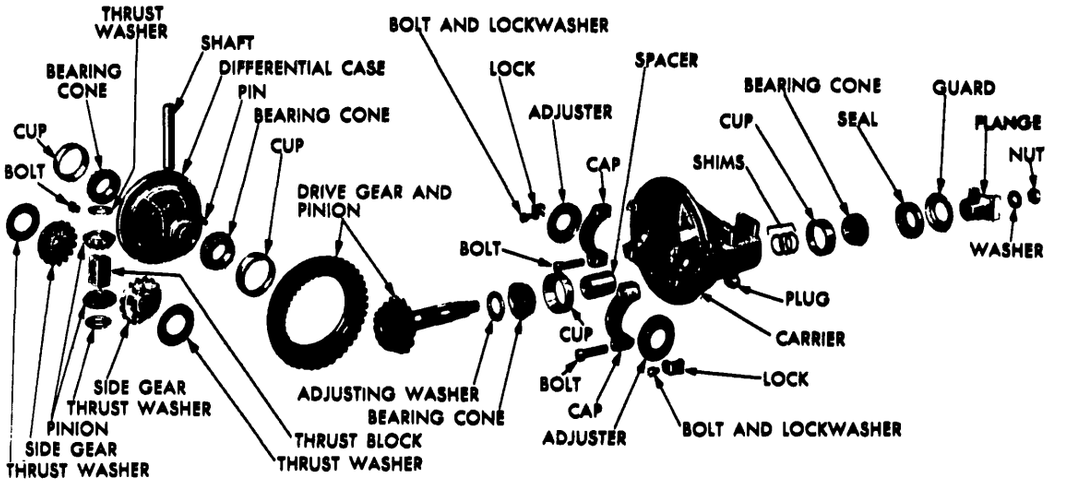
►*POWER-LOCK DIFF. OPTIONAL:* *See "P w r-L ck Differential (Plate Clutch Typ)".*

OVERHAUL: Disassembly - Remove carrier attaching bolts, remove carrier and mount it in suitable stand. Check ring gear-to-pinion backlash. Mark both differential bearing caps and adjusters (for reinstallation in original positions). *CAUTION - DO NOT interchange bearing caps.* Remove bearing caps and adjusters, then lift differential assembly out of carrier. Remove pinion nut and use Puller C-456 to remove pinion flange. Use Puller C-358 or C-748 to remove oil seal. Remove pinion bearing oil slinger, bearing cone, preload shims and spacer (no spacer used on Chrysler New Yorker & Imperial). Remove drive pinion, bearing and washer from carrier. Use Tool C-293-C and correct plates to remove bearing from shaft. Drive bearing cups out of housing. Remove ring gear from case (left hand thread capscrews) and reinstall differential case in carrier without any bearing endplay. Check ring gear flange runout. It should not exceed .003". Remove differential assembly, drive out pinion shaft cross pin and pinion shaft, rotate

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "CAGE" TYPE HYPOID (Continued)

side gear to remove pinions, thrust washers, and side gears. Use Puller C-293 and suitable plates to remove differential side bearings.



►*PINION OIL SEAL NOTE:* Can be removed and installed without removing differential bearing assembly or pinion. Remove pinion shaft nut, use Puller C-456 to remove pinion flange and puller C-358 or C-748 to remove oil seal. Soak new seal in thin engine oil for 30 minutes, use special tool C-359 to install oil seal in carrier housing.

R ass mbly - *NOTE* - If replacement parts are installed, or differential adjustment is necessary, the proper thickness washer (or shims) must be installed between pinion and rear bearing and pinion bearing preload readjusted. *S "Pinion S tting & Bearing Preload Adjustm nt" b low.*

►*PINION WASHER NOTE: Pinion washers furnished .084" to .100" thick in .002" steps. Shims (when used) furnish d .010", .0125", .015" and .018" thick.*

Differ ntial Cas R ass mbly: Install a thrust washer over hub of each side gear and install gears in case. Install differential pinion gears and thrust washers so that holes of both gears and thrust washers are properly aligned. Rotate gears 90° so that pinion shaft holes in case are in alignment with holes in gears and thrust washers. From the pinion shaft lockpin hole side of case, insert the slotted portion of pinion shaft through case, thrust washer and just through first pinion gear. Install thrust block between the two pinion gears so hole in block is aligned with pinion shaft and with ground sides of block facing the two side gears. Keeping all parts in proper alignment, push pinion shaft through until locking pin hole is in exact alignment with hole in case. *(NOTE* - Before installing shaft lock pin, rotate differential gears, making sure they rotate freely through the complete revolution). Check clearance between each gear and case with a feeler gauge. Clearance should be .001-.008". Install pinion lock pin through case from pinion shaft side of drive flange. Position each bearing cone on hub of case with taper away from drive gear, then with Tool DD-1005, drive cone in until it seats. Position drive gear on case aligning the holes in gear and case. Start all capscrews into threads in flange, then tap gear onto case with a fibre hammer until it seats properly on flange. Position drive gear between brass jaws of vise and alternately tighten each capscrew to 55 ft. lbs. (Chrysler & Imperial), 40 lbs. minimum (DeSoto), 35-40 lbs. (Dodge & Plymouth).

Carrier R ass mbly: Install pinion bearing cups squarely in carrier and pull into place with Tool C-758-D-3 and Adapter SP-535 with Washer SP-534 and Nut SP-533. Remove Tool. Make "Pinion Setting & Bearing Preload Adjustment" *(see below)*, then install preselected washer on pinion shaft and use Tool DD-955 (Chrysler & DeSoto), DD-996 (Dodge & Plymouth) and arbor press to install rear bearing. On Chrysler New Yorker & Imperial, install second preselected shim pack. On other cars, install bearing spacer, then install preselected shim pack. Insert assembly in carrier, add front bearing and seal (lip of seal facing front bearing) against shoulder in housing. Use installer, Tool 496 or DD-999 to start companion flange. Add plain washer (concave side down) and tighten nut to 240 ft. lbs. (Chrysler & DeSoto), 180-200 ft. lbs. (Dodge & Plymouth), then remove tool. Place differential case bearing cups over bearings and install complete assembly in carrier. Seat adjusters in pedestals and install caps and bolts, making sure that caps are correctly located. Using Tool C-406, turn right hand adjuster clockwise until backlash exists between gear and pinion. Back off adjuster nut several turns, then tighten lower pedestal bolts to 85-90 ft. lbs., leaving top bolts slightly loose. Check gear backlash, *see "Backlash Checking & Adjusting" below,* and adjust as necessary. With backlash properly adjusted install adjuster locks and tighten all bearing cap bolts to 90 ft. lbs. Recheck backlash. *CAUTION* -Whenever adjustment of differential assembly is changed to obtain correct tooth contact readjust differential bearing preload and backlash between gears.

CHRYSLER, DESOTO, DODGE, PLYMOUTH REAR AXLE

Gear Adjustment for Correct Tooth Contact: Apply gear marking compound to drive gear teeth, then apply a load against back face of gear with a round bar as drive gear is rotated. The contact pattern of a correctly adjusted assembly is well centered on drive and coast sides about 1/16" from edges of teeth. If tooth contact is across length of tooth, narrow and high on the tooth face, correct by moving pinion gear in toward center of drive gear by installing a thicker washer behind pinion. If tooth contact is across length of tooth, but narrow and low on the flank, correct by moving pinion gear away from center of drive gear by using a thinner washer behind pinion.

Backlash Check & Adjusting & Differential Bearing Pr . load Adjustment: With differential case assembly installed in carrier (see above), mount a dial indicator on housing so plunger rests against one of the ring gear teeth. *(NOTE* - Make sure indicator is properly positioned so plunger will accurately indicate exact amount of backlash). Check backlash at 90° intervals as gear is rotated, the stop at point of least backlash. Turn left hand (tooth side) bearing adjusting nut clockwise until only .001" backlash exists. *(NOTE* - Be sure right hand adjusting nut is screwed out so bearing cup can move without interference). At the point where .001" backlash is obtained, screw the right hand adjusting nut in until indicator just starts to move (to decrease the backlash) and install adjuster lock and attaching bolt. Tighten the **upper** right hand bearing cap bolt to 85-90 ft. lbs. *CAUTION - It is very important to have .001" backlash before upp r bolt is tightened).* Turn left hand adjusting nut **clockwise** until dial indicator shows .006" backlash. *(NOTE*- Considerable effort will be required to turn adjusting nut to last notch or two). This adjustment should be made so that adjuster lock and attaching bolt can be installed. Complete reassembly of carrier (see above).

Pinion Setting & Bearing Preload Adjustment: Install Gauge Block S-528 on end of dummy pinion shaft, Tool C-758-D-3. On Chrysler New Yorker and Imperial, assemble Washer, SP-2921 followed by pinion rear bearing and Sleeve, SP-1730 on dummy shaft. Insert the tool assembly in carrier, then install front bear-

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "CAGE" TYPE HYPOID (Continued)

ing. On other models, install Locating Washer, SP-2919 and pinion rear bearing on dummy pinion shaft, followed by pinion bearing spacer, with large bore of spacer next to rear bearing. Install Sleeve SP-1730 on tool, then install the assembly in carrier housing and install front bearing. On all models, install Compression Sleeve, SP-535, Centralizing Washer, SP-534, followed by Main Screw Nut, SP-533. Hold compression sleeve with Tool C-784 or C-3281 and tighten nut to 240 ft. lbs. (Chrysler & DeSoto), 180-200 ft. lbs. (Dodge & Plymouth). Install Bearing Arbor, Tool SP-561 in differential carrier bearing supports. Center arbor in pedestals, then insert a piece of .002" shim stock between arbor and each cap and tighten pedestal bolts to 10 ft. lbs. Select a pinion adjusting washer of sufficient thickness so it will just pass between gauge block end of setting tool and machined surface of arbor. For example, if a .090" washer can be installed, but a .092" washer cannot be forced between the two surfaces, the .090" washer should be used. Check end of drive pinion for an etched mark to determine thickness to be added or subtracted from the above selected washer. As an example, if mark on pinion is plus 2, a .002" **thinner** washer should be used for final assembly. If minus 2, a .002" **thicker** washer should be used. When correct washer has been selected for drive pinion, disassemble tool from carrier housing. Add the selected washer to tool, between tool spacer and rear bearing. On Chrysler New Yorker & Imperial, add Spacer SP-2920 over dummy shaft to seat against rear bearing. On all models, add the pinion bearing preload adjusting shims (removed at disassembly), then insert tool into carrier housing. Install front bearing on shaft and into position in bearing cup. Install tool spacer, nut and washer, then tighten nut to 240 ft. lbs. (Chrysler & Imperial), 180-200 ft. lbs. (Dodge & Plymouth). Rotate tool assembly to seat the bearings, then check bearing preload by revolving tool with an inch-pound reading torque wrench. The correct preload should be 25-35 inch-pounds (Chrysler & DeSoto), 20-30 inch-pounds (Dodge & Plymouth). Adjust preload as necessary by **adding a thicker** shim if preload is too great, or a **thinner** shim if preload is not sufficient. Complete reassembly as indicated. *See "Carrier Reassembly" above.*

③ - Ring gear thrust pad and screw used on 1953 Cars with Torque Converter. Not used on cars equipped with PowerFlite.

④ - "Bolted" barrel type. ⑤ - "Screwed" Barrel type.

►***DIFFERENTIAL PINION GEAR NOTE:*** Two or four differential pinion gears used. Overhaul and adjustment are the same except where noted.

►***OTHER MODELS NOTE:*** All other Chrysler, DeSoto & Dodge Models use "Cage Type" Hypoid. *See "Chrysler, DeSoto, Dodge & Plymouth Cage Type" Rear Axle.*

►***DIFFERENTIAL CASE NOTE—"Screwed Type" and "Bolted Type" Differential carrier caps used. Different disassembly & reassembly procedures required for each type. See "Differential Case Disassembly" below.***

►***1955 PINION NUT TIGHTENING CAUTION:*** A convex (Belleville Lockwasher) is used on some models. It is important that this washer be installed with the convex side contacting the companion flange nut. Tighten pinion nut as follows when this washer used. 240 ft. lbs. min. (Chrysler Windsor), 250 ft. lbs. min. (Other Chrysler Models) 300-330 ft. lbs. (DeSoto Models).

DESCRIPTION: Hypoid gear, semi-floating type with either "Screwed" or "Bolted" barrel type differential case. Two different types of pinion shaft assemblies requiring different overhaul and adjustment procedures.

REMOVAL OF AXLE: ***See "Rear Axle" on Car Model pages.***

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Remove rear wheels and hub and drum assembly using Tool C-845 (CAUTION—Do not strike end of axle shaft to loosen hub). Block brake pedal so it cannot be depressed and disconnect brake line at wheel cylinders. Remove rear axle drive shaft key and install sleeve Tool C-757 in axle bearing outer seal before removing brake support plate from axle housing. Remove shims from each end of axle housing and keep each set separate for reassembly. Remove axle shafts and bearings from housing using Tool C-499. Remove rear axle shaft inner oil seal.

Installation & Adjustment—Install axle shaft inner oil seal using Tool C-241. Insert axle shaft in housing making sure shaft and differential side gear splines are in alignment. Install axle shaft outer bearing (if removed) using Tool C-413. Install sleeve Tool C-757 in outer bearing oil seal before mounting brake support plate to axle housing to protect seal. Install brake support plate and tighten nuts to 30-35 ft. lbs. Connect brake tubes and bleed brakes. NOTE—If new axle shaft installed, it will be necessary to adjust the end play and center the axle. See Endplay Adjustment following.

Endplay Adjustment—Remove wheel and hub and tighten brake backing plate securely. Rap each axle shaft to be sure bearings and cups are seated, then place a dial indicator on axle drive shaft and housing in such a way to measure endplay of shaft. Check the endplay by moving axle shaft in and out. If endplay is not between .003" to .008", remove brake support plate and add or remove shims as required.

►***CAUTION***—When making adjustment of endplay, equal thicknesses of shims should be removed or installed on both right and left sides of axle housing, so as to retain central position of axle shaft thrust block.

Centralizing Rear Axles (Initial Installation of New Axle Shaft)—Install left axle shaft and bearing cone assembly (without grease). Drive bearing cup in as far as it will go using Tool C-413 to prevent damage to axle housing. Rear axle thrust block will be removed as far to the right as possible. With left bearing cup remaining at its innermost position, lay a straightedge across end of axle housing. Measure distance from straightedge to bearing cup face, to nearest 1/64". One-eighth inch minus the above measurement gives the thickness of shims required at left end to center the thrust block, (it is best to use a shim about .020" less than that required to center thrust block). Remove the left axle shaft, grease the bearing and reinstall bearing and shaft. Using the correct thickness of shims as determined above, install the support plate. Do not drive bearing cup in all the way (as the brake backing plate, when it is drawn up tight will push the bearing cup into the correct position). Install the right axle shaft and bearing (bearing should be clean and dry). Using Tool C-413, drive bearing cup in as far as it will go, meanwhile rotating axle

CONTINUED N NEXT PAGE

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID (C nt.)

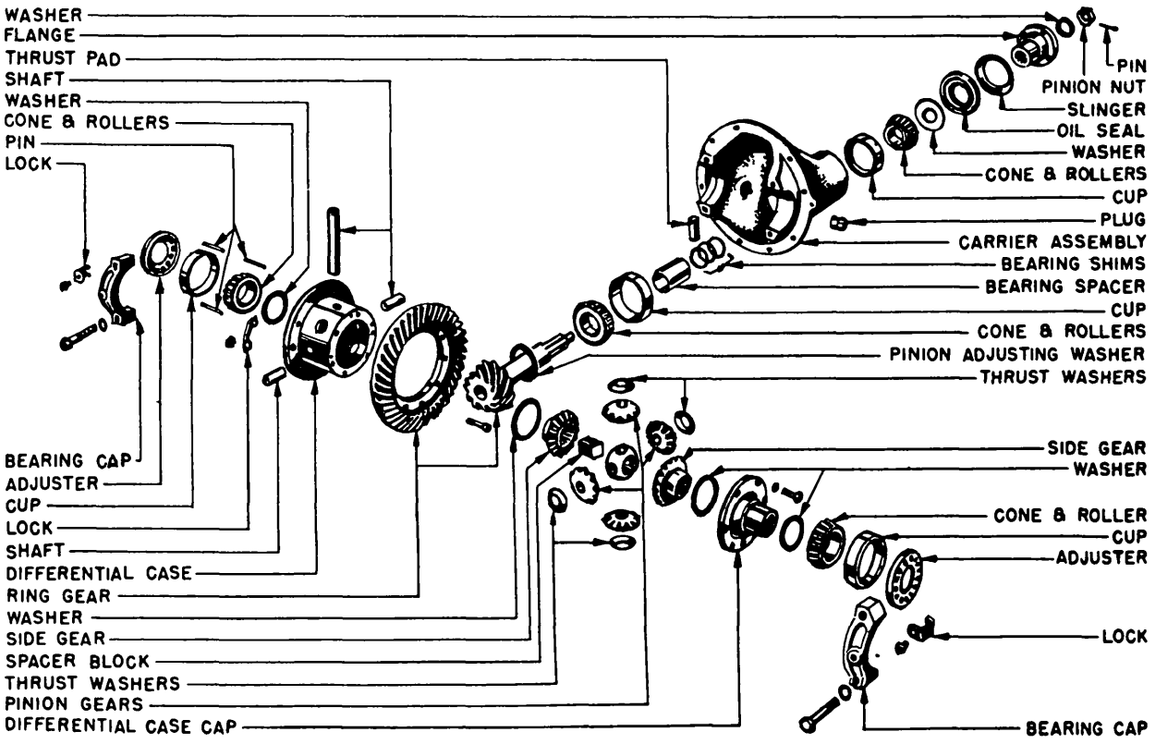
shafts to seat bearings, (Right bearing cup should protrude beyond housing end). Hold straightedge firmly across outer face of right bearing cup. Using a set of feeler gauges, measure accurately the distance between housing face and straightedge. This measurement gives thickness of shims that would give zero endplay if it were used. The shim thickness to be used is obtained by adding .003" to above measurement. If this gives a thickness that cannot be built up from existing shims, use the next larger shim combination. Remove the right axle shaft and grease the bearing and reinstall shaft and bearing and shim pack (as determined above), and complete the assembly.

OVERHAUL: (Disassembly)—Mount carrier assembly in stand, then mark both differential bearing adjusters and caps to insure reinstallation in correct position. Remove adjusting nut locks, back off adjusting nuts, take out bearing cap screws, remove bearing caps, and lift differential assembly out of carrier. Remove drive pinion shaft nut, pull universal joint drive pinion flange, and remove pinion shaft through rear end of carrier. Use puller C-293-C to remove rear bearing from shaft.
NOTE—Front oil seal can be replaced without dismantling carrier.

Differential Disassembly (Bolted Barrel Type): Place differential case in large vise with jaw protectors in place. Bend down tabs and remove drive gear to differential case attaching nuts and bolts. Tap drive gear off case with a fibre hammer. Mount case, bearings and cup assembly in carrier and check drive gear flange run-out which should not exceed .003". Remove case from carrier and remove differential case bearings with puller C-293 and No. 18 plates. Remove the six bolts attaching case cap to case, then remove three differential pinion shaft lock pins by driving them out of case. Drive long pinion shaft out of case with a brass drift and hammer, and remove axle shaft thrust block. Drive the short pinion shafts out of case and remove pinion shaft block. Remove pinion gears, side gears and thrust washers.

Differential Disassembly (Screwed Barrel Type): Mount differential case drive gear flange in large vise with jaw protectors, then remove differential case bearings with puller DD-914-89. Remove the differential case cap locking pins by center punching and drilling. Remove shell of pin in hole with punch. Heat outside of case with a torch DO NOT HEAT CAP, to a temperature of **not more than 360°-400°F.** (Check heat by means of a piece of soft solder, which will just start to melt when case is hot enough). Unscrew cap with special wrench DD-921 (start cover by jarring wrench handle with heavy hammer blow). Cool parts in oil and proceed with disassembly. Drive out the pinion shaft retaining pin, and with a hammer and drift, drive the long pinion shaft from case, and remove thrust block. Now drive the short pinion shafts from case and lift out pinion shaft block. Remove differential pinion gears, side gears and thrust washers from bottom of case.

►***DIFFERENTIAL CASE REASSEMBLY NOTE—Assembly of "Bolted Type" differential is identical to assembly of "Screwed Type," except that heating the case for cap installation is not necessary.***



Differential Case Reassembly (Bolted & Screwed Barrel Type): Place thrust washer over hub of differential side gear and lay in position in case. Line up the locking pin hole in long pinion shaft, with the hole in differential pinion boss (opposite boss has no pinion hole) and drive the pinion shaft in until it protrudes about 1/16" on inside of case. Place a pinion gear thrust washer on pinion so the side with indents faces pinion, then install pinion gear and washer on end of shaft that protrudes. Tap shaft and hold pinion until end of shaft is even with edge of pinion. Insert the pinion shaft block with punch marked sides facing the short pinion shaft holes and the side marked "1" facing up. Install thrust block and pinion shaft block. Install the opposite pinion gear and thrust washer, then drive shaft into final position. Drive one of the short pinion shafts into either of remaining holes until shaft protrudes 1/16" on inside of case. (Make sure lock pin holes line up). Install pinion gear and thrust washer and continue to drive until shaft enters hole in pinion shaft block. Install other short pinion shaft, washer and gear in same manner. Lock pinion shafts in place by installing three new locking pins in the holes and peen over.

("Screwed Barrel Type")—Clamp complete assembly in vise and heat outside surface of threaded portion of case with a torch flame as indicated in disassembly procedure. Dip threaded portion of cap in gear oil, and then assemble thrust washer and side gear in cap and screw into differential case with wrench DD-921. Tighten securely with blunt drift and hammer. Drive three new case cap lock pins 1/16" below surface of case and peen metal of case over pins with a ball end punch.

("Bolted Barrel Type")—Assemble a thrust washer and remaining side gear in cap. Using two of the attaching bolts as guides, position differential cap on case, then tap into place using a soft hammer. Tighten cap retaining bolts to 35-40 ft. lbs. Install ring gear on flange, then place locking tabs in position and install gear retaining nuts. Tighten nuts to 35-40 ft. lbs., and bend up tabs to lock nuts in position.

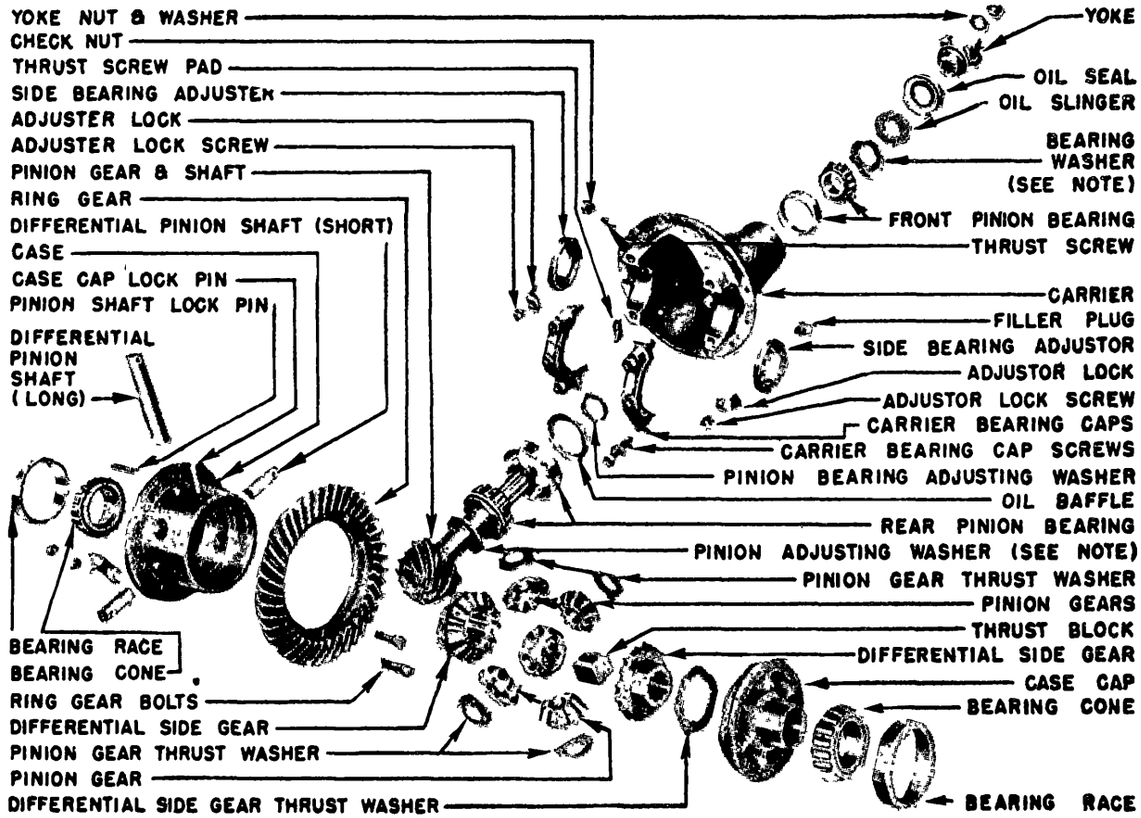
Pinion Bearing Preload: Preload check is made with Tool C-758-D which replaces pinion gear and shaft in housing when making check. Pinion adjusting shims or spacers are placed as indicated in model application above.

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE "BOLTED TYPE" HYP ID

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID (C nt.)

Pinion Bearing Preload



Model	Inch Lbs.
1954-56 Dodge (Wide Spacer or Shim Pack)	35-45
1954-56 Others (Either Spacer)	25-35

Pinion Preload Check (Pinions With Wide Spacer and Shim Pack)—Adjust pinion bearing preload BEFORE pinion gear setting is made. Coat drive pinion with hypoid lubricant, and assemble the drive pinion shaft rear bearing on main body of Tool C-758-D. Slide sleeve SP-1730, drive pinion bearing spacer and bearing adjusting shims over tool and insert the assembly into carrier. Slide front pinion bearing over tool and down into position in bearing cup. Slide compression sleeve SP-535 and centralizing washer over tool and down into position and install the compression nut. Tighten tool nut to torque indicated in "Tightening Torques" table below. Turn tool with a speed wrench to seat bearings, then check preload with an inch-pound torque wrench. Readings should be as indicated in table above. If adjustment does not conform to above readings, increase size of shim pack to **decrease** reading; decrease size of shim pack to **increase** reading. After correct preload setting has been obtained, leave tool in place for pinion setting.

Pinion Preload Check (Pinions With Single Narrow Spacer and Shoulder on Pinion Shaft)—***Pinion bearing preload must be checked AFTER pinion gear setting is made.*** Install pinion shaft adjusting washer and tool spacer SP-1371 over main body of Tool C-758-D with pinion shaft adjusting washer away from gear end of tool, then install pinion shaft rear bearing, and tool spacer SP-1370 and the pinion bearing adjusting spacer (that was removed from axle at disassembly). Insert assembly into carrier housing, then install front bearing onto shaft and into position in cup. Install compression spacer, centralizing washer and compression nut. Tighten nut to the torque indicated in "Tightening Torques" table below. Turn tool with speed wrench to seat bearings, then check bearing preload with an inch-pound wrench. Readings should be as indicated in table above. Increase size of spacer if reading is greater than upper limit, or decrease size of spacer if reading is less than lower limit. When reading is correct, remove tool and reassemble bearings and spacers to pinion shaft and install in housing.

Pinion Bearing Spacers—Spacers are available in sizes from .175" to .203" in steps of .002".

Pinion Bearing Carrier Assembly—After correct shims or spacer has been selected, disassemble Tool C-758-D and install pinion shaft adjusting spacer over pinion shaft and down against the machined surface of drive pinion. Install drive pinion rear bearing on pinion shaft and press it into place with Tool C-996. Slide bearing spacer and shim pack into position against rear bearing (if pinion shaft has a shoulder and narrow type spacer, install this narrow type spacer which was selected for correct

CHRYSLER, DE SOTO, DODGE "SCREWED BARREL TYPE" HYPOID

bearing preload). Insert assembly into carrier housing (lubricate all parts with hypoid lubricant). Slide front bearing over pinion shaft and into position in bearing cup, then install bearing oil slinger. Install new seal over pinion shaft and drive into position using Tool C-359. Install companion flange on shaft and install washer and nut. Tighten nut to torque indicated in "Tightening Torques" table below.

Pinion Nut Tightening Torque

Model	Ft. Lbs.
1954-56	② 180-320

② - 250 ft. lbs. (Chrysler Windsor), 300 ft. lbs. (Other Chrysler), 300-330 ft. lbs. (De Soto) with convex (Bellville Lockwasher).

Pinion Setting: (Without Tool C-758-D)—Pinions are marked "0" (standard) or "+" or "—" followed by figure (1 to 4 indicating necessary correction for other than standard "0" pinions). When installing new pinion of same marking as old pinion, use same spacer thickness for this new pinion. If new pinion marked "+" or "—" used to replace "0" standard pinion, use thinner washer (+ pinion), thicker washer (— pinion) than the washer used with the original pinion. The difference in thickness from the original washer should be equal in thousandths to the figure following the + or — mark on the pinion. Pinion position is controlled by spacer, installed on shaft between pinion and rear bearing. Pinion must be removed from carrier housing and bearings removed from shaft to change washer (or shims as used on some models) to correct pinion setting and gear mesh. See Ring & Pinion Gear Adjustment below also.

Washer Note—Pinion adjusting washers furnished in following thicknesses: .088", .090", .092", .094". Shims (when used) furnished .010", .0125", .015", .018" thick.

►*PINION SETTING NOTE*—Install Tool C-758-D as follows before setting pinion.

Chrysler 6 & Dodge V8 With Torque Converter—Install tool in same manner as that used for Pinion Bearing Preload (See above).

CONTINUED N NEXT PAGE

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID (C nt.)

Other Models—Assemble spacer SP-1371 to main section of Tool C-758-D, then install spacer SP-1370 and slide pinion rear bearing over spacer SP-1370 and up against spacer SP-1371. Insert tool as assembled into carrier housing and install front bearing over tool shaft and into position in bearing cup. Tighten tool compression nut so torque required to rotate tool assembly is as indicated in Pinion Bearing Preload table above, with bearing lubricated with hypoid gear oil.

Pinion Setting (With Tool C-758-D): Fasten Gauge Block SP-528 to rear end of main tool body, and place Arbor SP-561 in differential carrier bearing supports. Install bearing caps and bolts and tighten bolts to 10 ft. lbs. (NOTE—Remove all burrs and foreign material in bearing bores before installing arbor). Select a pinion washer that will just pass between arbor and gauge block (For an example: if a .090" can be inserted but a .092" cannot be forced between the two surfaces by hand, the .90" washer should be used even though it feels loose). Check pinion shaft end as it may indicate the amount that should be added or subtracted from the washer in the above check. (If mark on shaft indicated a +2, a .002" thinner washer should be used for final assembly. If a —2 were indicated, then .002" should be added to washer initially selected). When correct washer has been selected for the drive pinion, disassemble tool and proceed with pinion shaft installation (See Pinion Bearing Carrier Assembly above).

Spacer Washer Note—Spacers furnished in sizes from .084" to .100" thick, in steps of .002".

Differential Bearing Preload & Backlash Adjustment: When installing differential carrier assembly, turn adjusting nuts up to marks made before disassembly, then check bearing adjustment as follows: Check drive gear for runout. Gear should be true within .004". Screw out bearing adjusting nut at back face of drive gear, and screw in the opposite nut until ample backlash is obtained. Tighten lower cap bolts to 90 ft. lbs., leaving the top bolts fairly loose. Screw out adjusting nut on tooth side of drive gear, until nut clears cup. Screw in opposite adjusting nut until there is only a little backlash. Turn drive gear a few times by hand to seat bearings. With a dial indicator, find the point of least backlash on drive gear at 90° intervals. At the point of least backlash, screw in adjusting nut at back face of drive gear until .001" shows on indicator. Turn in adjusting nut on tooth side until indicator shows .006". Lock adjusting nuts in place and tighten both top cap bolts to 90 ft. lbs.

Ring Gear Thrust Pad Adjustment: Clearance between thrust pad and rear face of ring gear should be .006-.008". To adjust, loosen locknut on left side of carrier housing (nut and screw are tack welded together). Turn stud up finger tight, and back off so there is .006-.008" clearance between thrust pad and drive gear.

Mercury Sta. Wgn. (1954-56)

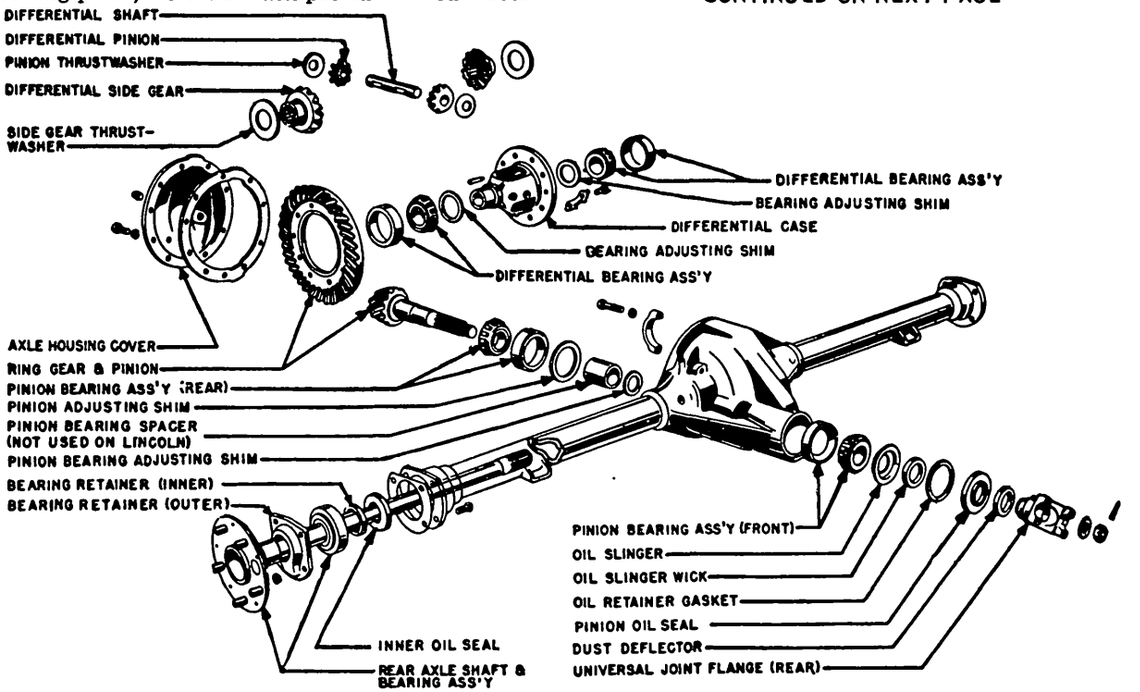
►CHANGES, CAUTIONS, CORRECTIONS

►*1956 LINCOLN & MERCURY REAR AXLE PINION SEAL SQUEAL CORRECTION:* A new seal, Part No. MC-4676-A having two sealing lips may be used to replace the old seal. Coat lips of seal with Lubriplate before installation.

►*1954-56 MERCURY REAR AXLE SHAFT ENDPLAY CORRECTION:* A "Clunking" sound on rough roads or sharp turns caused by excessive axle shaft endplay can be eliminated by installing shims between rear axle bearing and shoulder in axle housing tube. Measure axle shaft endplay with a dial indicator. If endplay is over .030" add shims as required to reduce the endplay to not less than .019". Make shims of steel or brass in thicknesses of .010" & .015". Inside diameter should be 2 9/16", outside diameter should be 3 1/8".

►**REAR AXLE IDENTIFICATION NOTE**—Metal tag attached to one axle housing cover screw stamped with number of ring gear and pinion teeth.

►***CAUTION—Re-install identification tag when housing cover replaced.***



DECRIPTION: Semi-floating, hypoid gear, Hotchkiss drive type. **This axle does not have a separate differential carrier assembly.**

AXLE SHAFT REPLACEMENT: Remove wheel, remove brake drum by taking out tinnerman nuts securing drum to axle flange. Rotate axle shaft until hole in shaft flange lines up with one of four bolts mounting backing plate and bearing retainer on housing, remove all bolts. Use Tool 4235A (sliding hammer) to remove axle shaft and bearing assembly from housing. Use care not to dislodge the brake backing plate or damage the oil seal in the housing. ***NOTE—If oil seal being replaced, disconnect brake tube from backing plate. Plate can be laid on floor without disconnecting brake cable.***

Wheel Bearing Replacement: Cut bearing retainer ring with chisel, slide ring off shaft, use Tool 4234 to press bearing off shaft in arbor press. When cleaning parts, DO NOT wash pre-lubricated wheel bearing with solvents (will remove lubricant) Press bearing on shaft, using Tool 4234, then press on new wheel bearing retainer ring. (CAUTION—do not attempt to press bearing and retainer on in one operation).

Oil Seal Replacement: Use Tool 4235-B to install seal in housing. Use great care to keep seal square with housing while installing. Seat seal **lightly** against

CONTINUED ON NEXT PAGE

LINCOLN, MERCURY, FORD "INTEGRAL CARRIER" HYPOID AXLE

FORD, LINCOLN, MERCURY "INTEGRAL CARRIER" TYPE (Continued)

shoulder in housing. Apply cup grease to seal surface before installing axle shaft.

Axle Shaft Installation: Use care not to damage oil seal when installing axle shaft. Tighten bearing retainer and backing plate bolts to 30-35 ft. lbs. Install brake drum and secure to axle flange with tinnerman nuts. CAUTION—If brake tube removed, reconnect and bleed brakes.

Drive Pinion Oil Seal Replacement: (Without removing Differential Carrier): Disconnect drive shaft at rear universal joint. Mark position of universal joint flange, nut & shaft with a punch, to insure installing at the same position. Remove pinion shaft nut and pull flange with Tool 4858-Q. Install an oil seal puller and pull seal from housing. To install, position seal in housing and drive into place with Tool 4676. Install flange on pinion shaft with marks in line, and install pinion shaft nut and tighten until it is tight on shaft with marks on flange, shaft, and nut aligned.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model page.*

REAR AXLE (Disassembly): Remove axle shafts (see Axle Shaft Removal above).

1)—Remove cover assembly and gasket and install axle housing spreader Tool 4000-A and spread axle housing not more than .015".

►***CAUTION—When using axle spreader tool to spread axle housing, do not spread more than .015" which is necessary for differential removal, and remove spreader immediately to avoid housing taking on permanent "set."***

2)—Mark differential side bearing caps to insure correct reassembly (NOTE—Lincoln bearing caps are marked at factory with a letter or a figure stamped on cap, and on the housing at a point adjacent to the cap. Left side marks are horizontal and right side marks are vertical). Remove bearing caps and pry differential assembly loose from housing and lift assembly out.

3)—Remove nut from pinion shaft, holding the flange with Tool 4851-C. Remove flange with Tool 4858-D (Lincoln & Mercury), 4858-Q (Ford). Drive pinion toward rear of housing with Tool 4201, and withdraw pinion and rear bearing cone and roller assembly.

4)—Remove oil seal from front end of housing with Tool 1175-B. Lift out pinion shaft ring gasket, wick, slinger and front bearing cone and roller assembly.

5)—Remove pinion front bearing cup with Tool 4628-B, and rear bearing cup with Tool 4628-D. ***CAUTION—Do not loose shims located in housing back of rear bearing cup. If pinion is not to be replaced, these shims will be installed at reassembly.***

Differential Disassembly: Remove differential side bearings with Tool 4221-C, and remove shims located between bearings and carrier **(Note the number and thickness of shims behind each bearing as these shims must be replaced unless new parts are to be installed).** Pry ring gear bolt locking tabs away from bolt heads and remove capscrews and ring gear. Drive out pin securing differential pinion shaft in case and take out shaft, pinion, side gears, and thrust washers.

Diff rential Assembly: Lubricate all parts with differential lubricant. Install side gears and thrust washers, pinion gears and thrust washers and the differential pinion shaft. Secure pinion shaft with locking pin (stake pin in place to avoid having it fall out). Position the ring gear on the case and secure in place with capscrews and new lockwashers. Tighten capscrews to 50-60 ft. lbs. Bend tangs of lockwashers up against capscrews.

►***REPLACEMENT DIFFERENTIAL GEAR & PINION CAUTION: See Parts Production Change above for different type gears and pinions which must be used together.***

►*1955 LINCOLN & MERCURY TOOL NOTE:* Tool 4205-A is available for use on 1955 and later Lincoln & Mercury Rear Axles. Tool consists of two dummy bearings which replace differential side bearings in making adjustments as outlined below.

Differential Bearing Preload & Ring Gear Backlash Adjustment (1954 Ford Sta. Wgn. & Sed. Del., 1954 Lincoln & Mercury): Install side bearings on differential assembly **without shims.** Install differential assembly in the housing (without pinion shaft installed) and use a dial indicator to measure total endplay of unit, then note this figure. Select shim pack equal to total endplay **plus** shims equal to desired bearing preload (.007-.009" Ford; .005-.009" Lincoln & Mercury), for TOTAL SHIM PACK of side bearings. After pinion installed in housing (see below), reinstall differential assembly **without shims** and measure endplay on left hand side (from no backlash to maximum backlash). Select shims equal to this measurement (from total shim pack), **less .003-.008" backlash** for installation on left hand side. Select shim pack equal to total endplay plus preload and less thickness of left shim pack (from total shims) for installation on right hand side.

Differential Bearing Preload & Ring Gear Backlash Adjustment (1955-56 Ford, Thunderbird & Interceptor, 1955-58 Ford Sta. Wgn. & Sed. Del., 1954-56 F-100 Truck, 1955-58 Lincoln, Continental & Mercury): Install side bearings on differential assembly without shims (see Lincoln & Mercury Tool Note above). Install differential in housing (without pinion shaft assembly in place) and use dial indicator to measure total endplay of differential assembly in housing, then record this reading. Remove differential assembly and install pinion assembly (see below), Reinstall differential assembly and measure endplay on left side (no backlash to maximum backlash). This measurement represents shim pack for left side. Subtract this left side measurement for total endplay reading and add .015-.020" (Ford) .010-.015" (Lincoln & Mercury). This total will represent the shim pack thickness for the right side and will include both backlash and preload. Remove differential assembly (remove Tool Lincoln & Mercury and install side bearings). Reinstall assembly in housing with shim packs as determined above.

Ring Gear Backlash & Gear Mesh: Measure backlash with a dial indicator. If not within limits of .003-.006" (Ford Truck), .003-.008" (Others), adjust by shifting shims behind side bearing cups from one side of the carrier to the other but **do not change total shim thickness** which would affect bearing pre-load above. Check backlash at four equal spaced points around ring gear. Backlash must be within limits and must not vary more than .002" between these checking points.

REAR AXLE (Assembly): Assemble rear axle in the following sequence:

Pinion Bearing Assembly Installation: Lubricate all bearings and thrust washers with differential lubricant before installation. Install front and rear bearing cups in housing using Tool 4628-D (Lincoln & Mercury), Tool 4628-N (Ford) for rear bearing cup; Tool 4628-B (Lincoln & Mercury, Tool 4628-N (Ford) for front bearing cup *(CAUTION*—Re-install shims behind rear bearing cup. If new parts being used, install approximately .030" shim thickness to check pinion setting). Install rear bearing cone and bearing assembly on pinion shaft, insert pinion in housing and check pinion setting (below) to determine correct thickness of shims required. If correction required, remove rear bearing cup from housing and re-install with correct number and thickness of shims behind bearing cup. Lubricate bearings and insert pinion in housing, place bearing spacer on shaft (spacer not used on Lincoln), re-install bearing adjusting shims on shaft (same thickness as removed unless new parts installed, in which case install approximately .065" shim thickness to check bearing adjustment). Install pinion shaft front bearing cone and roller assembly with Tool 4858-B and tighten tool nut to torque indicated in "Tightening Torques" table below. Check pinion bearing preload (see below) and add or remove shims from shaft behind front bearing cone until correct bearing pre-load secured. Remove tool, install oil slinger, wick, and gasket, and oil seal (use Tool 4676). See that oil deflector on companion flange is in good condition (new deflector can be installed with Tool 4859), install companion flange with Tool 4858-B tighten companion flange nut to torque indicated

Pinion Nut Tightening T rque

Car Model	Ft. Lbs.
Ford Sta. Wgn. & Sed. Del. (1954)	140-180
Ford Sta. Wgn. & Sed. Del. (1955-56)	200-220
Ford Truck F-100 (1954)	140-180
Ford Truck F-100 (1955-56)	200-220
Ford Truck F-250, P-350 (1955-56)	200-250
Ford Thunderbird & Interceptor (1955-56)	200-220
Lincoln (1954-58)	100-150
Continental (1956-58)	100-150
Mercury (1954-56)	100-150

Pinion Bearing Preload: Turning torque with pinion rotating should be as indicated in table below (disregard torque required to start pinion) with nut on end of pinion shaft properly tightened to torque indicated in "Tightening Torques" table above. To check preload, position axle so that pinion shaft is vertical, use torque indicator (with Tool 4858-B) and note indicator reading with shaft rotating.

Adjustment—If torque reading low, remove shims from shaft behind front bearing cone; if reading high, add shims at this point. Shims furnished .003", .005", .010", .030" thick.

CONTINUED ON NEXT PAGE

FORD, LINCOLN, MERCURY "INTEGRAL CARRIER" TYPE (C ntinued)

Pini n B aring Preload

Car Mod l	Inch-Lbs.
Ford Sta. Wgn. & Sed. Del. (1954)	8-12
Ford Sta. Wgn. & Sed. Del. (1955-56)	10-30
Ford F-100 Truck (1954)	8-12
Ford F-100 Truck (1955-56)	10-30
Ford F-250, P-350 Truck (1955-56)	10-30
Ford Thunderbird & Interceptor (1955-56)	10-30
Lincoln (1954-58)	ℂ 8-12
Continental (1956-58)	ℂ 8-12
Mercury (1954-56)	ℂ 8-12

ℂ - 18-20 inch lbs. if bearings are new.

Pinion Setting: Pinion position must be checked when new parts installed or when same number and thickness of shims, as removed from behind rear bearing cup, not re-installed. Check pinion position with Pinion Depth Gauge Tool 4020-A (Ford), 4020-B (Lincoln & Mercury) as follows: With pinion inserted in housing, install gauge in differential side bearing bores (use large diameter rings of Tool 4020-B for Lincoln, and small rings for Mercury). Install bearing caps and torque capscrews to 60-70 ft. lbs. Bolt anvil clamp on axle housing flange directly over pinion, install anvil under clamp so that anvil rests on face of pinion and contacts gauge micrometer (Lincoln & Mercury). Check micrometer reading (Micrometer is part of Tool 4020-B. Outside type micrometers must be used with Tool 4020-A) which should agree with table below for all standard pinions marked "0." If micrometer reading greater than figure in table, subtract equal thickness of shims from .030" shim pack installed behind pinion rear bearing cup; if micrometer reading less than figure in table, add equal thickness of shims as above; and finally correct this shim thickness for all pinions marked other than standard "0" pinion as follows:

Pinion Marking Note—Standard pinions are marked "0." When installing a "—" (minus) pinion ADD shims equal in thousandths to the figure following this minus sign on the pinion; for "+" (plus) pinions, SUBTRACT shims similarly from the standard shim thickness (for pinions marked "0"). These shims furnished in thicknesses of .003", .005", .010" (Ford), .0025-.0035", .0045-.0055", .009-.011", .027-.033" (Lincoln & Mercury).

►***CAUTION—Changing shim thickness to adjust pinion position will disturb bearing adjustment unless same shim thickness is added or removed from shaft at front bearing cone***

FORD & MERCURY "SEPARATE CARRIER TYPE" HYPOID

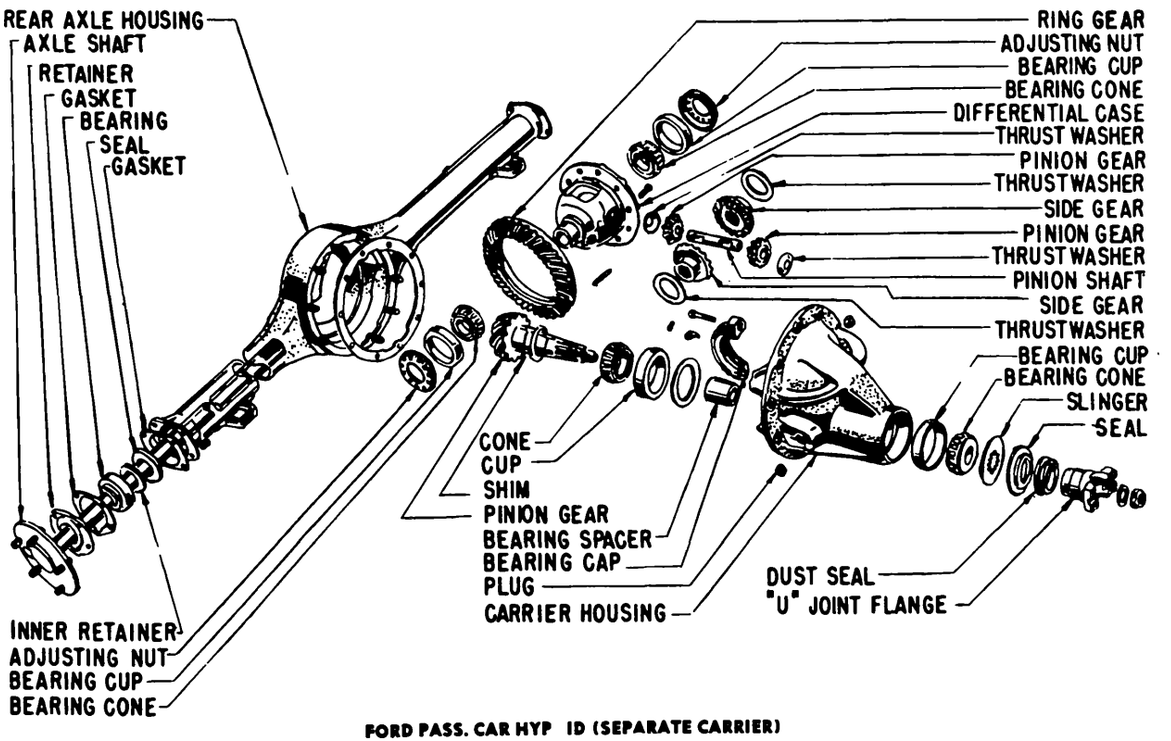
F rd Pass. Cars, Exc. Sta. Wgn. & Sed. Del. (1954)
F rd Pass. Cars, Exc. Sta. Wgn., Sed. Del., Thunderbird & Polic Int rc pt r (1955-56)
Mercury Sta. Wgn. (1954)

►*NOTE: S "Ford, Lincoln, Mercury Hypoid (Integral Carri r)" for other Ford & Mercury applications.*

►CHANGES, CAUTIONS, CORRECTIONS

►***REAR AXLE LUBRICATION CAUTION: If necessary t chang rear axl lubricant before 5000 miles, refill axl with M-4642-A or B lubricant. After 5000 miles of peration, Multi-Purp s type gear lubricant can be used for r filling.***

►*1954 DIFFERENTIAL GEAR CASE CAUTION:* Differential Gear Case, Part No. 1A-4205 (Painted Red), used with 3.31-1 ratio carrier and gear assembly. Part No. 8A-4205 used with other ratios. THESE CASES ARE NOT INTERCHANGEABLE.



►*1954 MERCURY REAR AXLE "CLINK" CORRECTION:* Hardened, phosphate coated slinger, Part No. MA-4670-A, has been released to alleviate above condition, replacing Part No. 0A-4670. To install proceed as follows: Remove drive shaft assembly. Remove companion flange only from rear axle. Polish end of companion flange where it contacts slinger, with fine crocus cloth. Reassemble companion flange, torque pinion nut to 150 ft. lbs. Install drive assembly.

►*1956 PINION BEARING SPACER PRODUCTION CHANGE:* A new pinion bearing spacer, Part No. B6A-4662-A with indentations on the inner surface has replaced the earlier type paper lined spacer. The later type spacer will center correctly on pinion and prevent cocking of spacer. Do not use the paper liner with later type spacer.

►*1956 3.22-1 RATIO REAR AXLE RING GEAR CHANGE (CARS WITH 312" THUNDERBIRD ENGINE):* The ring gear diameter has been increased from 8 1/4" to 8 1/2" and the attaching bolts have been increased from 3/8" to 7/16". A limited number of ring gears and pinions were released with 3/8" bolts. If failure is encountered with this ring gear, and the B6A-4209-J gear set is not available, it will be necessary to use the B6A-4209-K gear set and replace the differential gear case with a B6A-4205-D gear case.

►*1956 DRIVE PINION OIL SLINGER PRODUCTION CHANGE (Also a service replacement change on all 1950-56 Models):* To prevent losing pinion bearing preload due to wear of drive pinion oil slinger, a new sling-

CONTINUED ON NEXT PAGE

FORD PASS. CAR HYP ID (SEPARATE CARRIER)

FORD & MERCURY HYPOID "SEPARATE CARRIER TYPE" (Continued)

er, Part No. B6A-4670-A which is made of harder material, is being used in production and for service replacement. Install the later type slinger whenever disassembly of the rear axle is necessary.

► *1955-56 DIFFERENTIAL GEAR CASE REPLACEMENT CAUTION:* To prevent installation of the wrong differential case, the attaching flange thickness should be measured before installation. It is important that the proper length ring gear bolts be used with the differential case. When using differential gear case, Part No. B5A-4205-B (7/16" flange), the 43018-S (7/8" long) attaching bolts must be used. If differential gear case, Part No. B6A-4205-B (23/64" flange) is used, the 46027-S (3/4" long) attaching bolts must be used.

► *1955-56 RING GEAR TO DIFFERENTIAL CASE ATTACHING BOLT TIGHTENING SPECIFICATION CHANGE:* Tightening specifications for the 3/8" diameter bolts have been changed from 35-40 ft. lbs. to 45-50 ft. lbs. Assemblies using the 7/16" diameter bolt (see 3.22-1 Ratio Rear Axle Change above) must be tightened to 75-85 ft. lbs.

DESCRIPTION: Semi-floating hypoid gear, Hotchkiss drive, with separate differential carrier assembly which can be removed for work.

AXLE SHAFT REPLACEMENT: Remove wheel and tire assembly, then remove the Tinnerman nuts that secure brake drum to axle flange. Remove brake drum. Working through the hole provided in axle shaft flange, remove nuts securing brake carrier plate to axle housing. Pull axle shaft assembly out of housing with Axle Shaft Puller Tool 4235-N (Ford), 4235-A (Mercury). Do not dislodge brake plate or damage oil seal in housing. Install one nut to hold brake plate in place.

Wheel Bearing Replacement (Ford): Remove bearing retainer from shaft with Tool 2240-N. Use puller to remove bearing or grind through both races and lift off bearing *(CAUTION–Do not re-use bearing).* To install bearing, place retainer plate on shaft, using Tool 1225-N to press new bearing firmly in place against shoulder on shaft. Press retainer ring firmly against bearing.

Wheel Bearing Replacement (Mercury): Cut wheel bearing retainer with chisel, then remove bearing with Tool 1225-C. Use Tool 1225-B to replace bearing. Press into place. Use same tool to press on bearing retainer.

► *CAUTION: Use extreme care not to damage oil seal bearing surface on axle.*

Oil Seal Replacement–Soak new seal in engine oil for at least ½ hour. Use Tool 4235-N or A to drive seal into place against shoulder in housing. Check fit of seal in housing to prevent oil leaks around seal.

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Models pages.*

REAR AXLE OVERHAUL: *(NOTE–It is not necessary to remove rear axle assembly from car for overhaul).* After axle shafts removed, proceed as follows:

Differential Carrier: Removal–Disconnect propeller shaft rear universal joint. Drain lubricant from housing and remove carrier to housing nuts. Remove carrier from housing.

Disassembly–Before disassembling carrier, clean thoroughly and inspect drive pinion, drive gear, and case assembly for endplay. Inspect gear tooth pattern to determine if gears are worn, defective, or out of adjustment. Check backlash and drive gear runout. Mark differential bearing caps and carrier supports with matching numbers to insure proper reassembly. Remove differential adjusting nut locks, bearing caps and adjusting nuts. Lift differential assembly out of carrier. Remove universal joint flange nut and washer, then pull flange off drive pinion. Lift drive pinion, rear bearing and bearing spacer out of carrier. Remove oil seal using Tool 1175-H or B, and lift oil slinger and bearing out of case. Drive pinion bearing cups out of carrier with a brass drift, or use Tool 4628-P or F. (1954-55), T55P-4616-A (1956).

Differential Case Disassembly - Remove differential bearings with Puller 4221-N or C (1954-55), Puller T56L-400-A (1956). Remove drive capscrews and tap off gear with soft hammer. Drive pinion shaft locking pin out of case with drift working from drive gear side of case. Remove pinion shaft and differential bearings, side gears, and thrust washers.

Drive Pinion Disassembly - Remove rear bearing from drive pinion with Puller 4221-N or E. If tool not available, insert a press plate between inner race and drive pinion out of bearing. Remove shims from drive pinion, noting total thickness of shim pack for use at reassembly.

Differential Carrier: Reassembly–If replacement of drive pinion or drive gear is necessary, both parts must be replaced. When differential case is being replaced, be sure that the new case is the same as the original case. Coat all parts with differential lubricant before installation and use new gaskets.

Drive Pinion Adjustment (Master Pinion Tool Method)– Make sure that bores in carrier are free of burrs and metal chips, then install drive pinion bearing cups in carrier with Tool 4228-N (1954-55), F55P-4616-A (1956). Slide drive pinion rear bearing on Master Pinion Tool 4610-CC (1954-55), 4610-PP (1956), then position tool in carrier. Install front bearing on tool, then install universal joint flange, washer, and nut using Tool 4858-P or E. Oil bearing, then tighten nut until bearing preload is 15-20 inch pounds. Check preload with Tool 4610-N. *NOTE - Alternately turn pinion while tightening nut to properly seat bearings.* Install pinion Depth Gauge 4610-A or 4610-P. Measure distance between depth gauge and pinion with a 2-3" micrometer *NOTE - On 1956 models, use adapter rings on depth gauge (bores are 1/8" larger). Use approximately a 1/8" spacer between universal joint flange and front pinion as bearing cup is approximately .108" deeper in carrier casting.* Remove pinion depth gauge and master pinion tool from carrier. Check number etched on end of pinion to be installed. With this number and the micrometer reading select total shim thickness requirement. *See "Pinion Setting Shim Tables" below.* As an example, a reading of 2.531" from Tool 4610-A (reading from Tool 4610-P would be .500" less) with a pinion marked "17" requires .033" in shims. Shims are available in .010", .011", .012", .013" and .016". Install proper shims on pinion shaft, then press rear bearing on pinion until it is seated against shims *(CAUTION - When checking pinion depth, always use the same bearings that are to be used for service in the axle).* Install pinion assembly in carrier, then install a new bearing spacer and front bearing. Place oil slinger and seal on pinion shaft and drive seal into place with Tool 4676-A. Install universal joint flange with Tool 4858-P or E, and install washer and nut. Alternately turn pinion while tightening nut until bearing preload is 22-28 inch pounds (new bearings 1954-55), 18-24 inch pounds (new bearings 1956) or 13-18 inch pounds (used bearings all years).

Drive Pinion Adjustment (Tooth Pattern Method)– Make sure bores in carrier are free of burrs and metal chips, then install drive pinion bearing cups in carrier. If the original drive pinion is being used, install the original shim pack on drive pinion. If a new pinion is

FORD & MERCURY HYPOID "SEPARATE CARRIER TYPE" (Continued)

being installed, and the drive pinion marking is the same as the old pinion, install original shims. However, a thicker shim pack is necessary if the number on the pinion is greater, or a thinner shim pack if the number is smaller. For instance, if the number on the old pinion was "15", and the number of the new pinion is "17", install a .002" thicker shim pack. Conversely, a .002" thinner shim pack should be used if the new pinion number is "13". If the old bearings are to be used, increase the shim pack thickness .002". If the old shims are not available, use a shim pack .030" to .032" thick (1954-55), .015" thick (1956) for a trial build-up. Install shim pack, then install pinion rear bearing. Install drive pinion assembly in carrier, install a new bearing spacer then install pinion front bearing. On all models, install oil slinger on top of front bearing and coat outer diameter of seal with thin coating of sealer. Drive seal into place with Tool 4676-A. Install universal joint flange with Tool 4858-P or E. Install flange washer and a new nut. Alternately turn pinion while tightening nut. *CAUTION - Do not damage spacer on drive pinion by over-tightening drive pinion nut.* If new drive pinion bearings and a new oil seal have been installed, tighten drive pinion nut until bearing preload is 22-28 inch pounds (1954-55), 18-24 inch pounds (1956) for new bearings, or 13-18 inch pounds (All) for used bearings.

Differential Case Reassembly-Install differential side gears, pinions, and thrust washers in differential case. Install pinion shaft and pinion shaft lock pin. Position ring gear on case and install the drive gear capscrews and tighten screws to 35-40 ft. lbs. Drive differential bearings on case hubs with Replacer Tool 4222-N or H, until they are flush with shoulder on case.

Installation-Place differential side bearing cups on bearings and position differential case assembly in carrier so the adjusting nuts will engage approximately the same amount of threads at each end of case. Thread adjusting nuts in carrier against bearing cups. Be sure that nut threads index with carrier threads. Carefully position the bearing caps on adjusting nuts, aligning marks made during disassembly. Be sure bearing cap threads index with adjusting nut threads. Install bearing cap bolts and tighten bolts until snug (final tightening will be made after ring gear and pinion tooth contact pattern is adjusted). Turn adjusting nuts while tightening bolts, to make sure threads are aligned. Back off the bolts ¼ turn to allow cups to move. Make sure the right hand adjusting nut is loose, then tighten the left hand nut (gear side of differential) until drive gear meshes with drive pinion. Feel the backlash as the nut is being tightened. Continue tightening the nut until no backlash is evident. Tighten the left hand nut two additional notches to properly seat and align the bearing cup. Loosen the nut until it just contacts the bearing cup when the backlash is zero. Tighten the right hand adjusting nut until it contacts the bearing cup, then tighten the right hand nut an additional 3 to 3½ notches to properly preload the differential side bearings. Tighten bearing caps to 75-80 ft. lbs. Install a dial indicator and measure the backlash in several locations (*CAUTION-If backlash readings vary more than .003", the runout of the gear is excessive*). The correct backlash is .003-.008". If not within limits, loosen bearing cap bolts ⅛ turn, and move drive gear and case assembly as required. To move the case assembly, loosen one adjusting nut one notch and tighten the other adjusting nut one notch.

Gear Tooth Contact-*(NOTE-New gear sets have a heavy-load tooth contact pattern rolled on the gear teeth with a special machine. When a new set of gears is installed, duplicate this pattern as closely as possible).* Paint gear teeth with a suitable gear marking compound, place a load on the pinion flange and turn drive gear back and forth until a clear contact pattern is obtained. Compare this pattern with the tooth patterns shown in Rear Axle Section of Manual. *CAUTION-Whenever the drive pinion position is changed a new bearing spacer must be used to establish the correct preload.*

Differential Carrier Installation: Place a new gasket on rear axle housing studs, then position carrier assembly on housing. Install axle ratio identification tag on one of the upper carrier studs. Install all stud nuts and tighten to 30-35 ft. lbs. Fill axle housing to a level of the filler plug hole with rear axle lubricant.

EDSEL, FORD, MERCURY "DEEP-OFFSET" HYPOID

Edsel (1958-60)
Ford Pass. Cars (1957-60)
Ford Thunderbird (1957-60)
Ford F-100 Truck (1957-60)
Mercury (1957-60)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1958 PINION OIL SEAL PRODUCTION CHANGE (To Reduce Squeal and Oil Leakage):* New 3" Oil Seal B8A-4676-B (Ford & Edsel), WAT-4676-B (Mercury) with related parts used in later production cars. Universal Joint Flange B8A-4851-A has smaller diameter dust deflector and can be used to service either 3" or 4 1/8" seals. *NOTE - DO NOT use Oil Flange Assembly WAA-4851-C with 3" seals.* New Drive Pinion Retainer B8A-4617-B; Seal B8A-4676-B (Ford & Edsel), WAT-4676-B (Mercury); Flange Assembly B8A-4851-A, can be used with both 3" and 4 1/8" seals.

▷*1958 REAR AXLE LUBRICANT LEAK CORRECTION:* Caused by leak around housing thread bolts. To correct, replace early type carrier bolts (No. OA-44044-A) with new bolt (AJ-44044-A) with larger head and apply non-hardening sealer to threads before installation.

▷*1958 MERCURY REAR AXLE PRODUCTION CHANGE (312" Eng.):* New Differential & Carrier Assembly (3.56-1 ratio) released for production (Std. & O.D.). New assembly has smaller side bearings, 6¾" ring gear and a rear axle drive pinion bumper. The new assembly will not be released for service.

▷*1959 MERCURY (WITH 383" & 430" Eng.) DIFFERENTIAL CARRIER & ADJUSTING UNIT PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* A new differential carrier, Part No. B9AW-4017-A having .031" larger adjusting nuts is being used in production and can be used to service all 1957-59 models equipped with the large differential case side bearings. The new adjusting nut, Part No. B9MW-4067-A, is identified by the letter "L" stamped on it. Previous adjusting nuts were not stamped.

▷*1957-60 MERCURY REPLACEMENT RING GEAR NOTE:* Replacement ring gears now being furnished for service replacement are approximately ¼" larger in diameter than previous ring gears. If there is insufficient clearance in rear axle housing for the later type gear, grind off enough of housing at point of interference for installation of gear.

▷*1960 MERCURY REAR AXLE GRINDING NOISE AND/OR AXLE SHAFT SPLINE FAILURE CORRECTION:* If this condition is encountered, measure the distance between spring seat and backing plate flange on rear axle tube. The correct housing will measure 5½". If housing measures 6½", an incorrect housing is installed and must be replaced.

DESCRIPTION: Banjo type housing, semi-floating type with "deep-offset" straddle mounted drive pinion. A separate differential carrier assembly is used which can be removed for overhaul without removing rear axle assembly from car. Power Transfer Differential optional in 1958 on Edsel & Mercury.

AXLE SHAFT REPLACEMENT: Remove wheel and tire assembly and then remove nuts holding brake drum to axle flange. Remove brake drum. Working through holes in axle shaft flange, remove nuts attaching wheel bearing retainer. Pull axle assembly out of housing. (*NOTE* - Be careful not to dislodge brake plate - install one nut to hold brake plate in place after axle shaft is removed). To install, reverse removal procedure, tighten bearing retainer nuts to 30-35 ft. lbs.

Oil Seal & Wheel Bearing Replacement: Remove axle shaft from housing. Remove bearing inner retainer and bearing using Bearing Puller T57L-1225-P. Inspect machined surface of axle shaft and axle housing for rough spots which might affect sealing action of oil seal. Remove any burrs or rough spots. Press a new bearing on shaft using Tool T57L-1225-N, installed in an arbor press, until bearing is seated firmly against shoulder on shaft. Press bearing inner retainer on shaft with bearing installation tool until retainer seats firmly against bearing. Install oil seal.

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model pages.*

OVERHAUL

DIFFERENTIAL CARRIER ASSEMBLY REMOVAL: *(NOTE - It is not necessary to remove complete rear axle assembly from car for overhaul).* Drain rear axle

CONTINUED ON NEXT PAGE

EDSEL, FORD, MERCURY "DEEP-OFFSET" HYPOID (C ntinu d)

assembly, then clean area around point where carrier and housing meet. Remove axle shafts, then remove nuts retaining carrier to axle housing. Remove carrier.

EDSEL, FORD & MERCURY REAR AXLE ASSEMBLY

►*1959-60 TIGHTENING TORQUE SPECIFICATION NOTE: Tightening specifications are different for these models as shown in following table*

Tightening Specifications

	Ft. Lbs.
Differential Bearing Capscrews	70–80
Diff Bearing Adjusting Nut Lock Bolts	15–20
Carrier-to-Housing Nuts	30–40
Pinion Retainer-to-Carrier	30–40
Drive Gear Attaching Capscrews	60–65
Rear Axle Shaft Bearing Retainer Nuts	30–35

DISASSEMBLY: *NOTE* - Before disassembling differential carrier, mount a dial indicator on carrier and check ring gear backlash which should be .004-.009". Check contact pattern on gear teeth (see "Gear Tooth Contact Pattern" below), and if found to be erratic, check runout of gear which should be .003" max. Loosen differential bearing cap bolts, then tighten them to 25 ft. lbs. Remove adjusting nut locks, then carefully loosen one of the adjusting nuts to determine if any differential bearing preload remains. If there is at least one notch of preload remaining, bearings may be reused if they are not pitted or damaged.

1) Mark one differential bearing cap and support to insure proper reassembly. Remove adjusting nut locks, bearing caps, and adjusting nuts. Remove differential assembly from carrier. If differential bearings are to be removed, use Tool T57L-4220-A (Ford), 4221-AE and 4221-C-13 (Mercury), to remove bearings.

2) Remove bolts attaching ring gear to differential case, then press gear from case or tap it off with a soft hammer. Using a drift, drive out differential pinion shaft retaining pin and separate the two-piece differential case. Drive out pinion shaft with a brass drift and remove gears and thrust washers.

3) Turn carrier case upright and remove the five bolts securing pinion retainer to carrier, then remove pinion retainer assembly. Remove pinion "O" ring seal from retainer, and remove pinion shim *(CAUTION - Be careful not to damage mounting surfaces of retainer and carrier)* Measure thickness of shim for reference at reassembly.

4) If pilot bearing is to be replaced, drive pilot bearing and retainer out with Tool T57L-4625-A and T53L-200-A (Ford), 4625-K (Mercury). Use the same tools to install bearing, driving it in until it bottoms. Install retainer, with concave side upward, using the same tools as for bearing installation *(CAUTION - Be careful not to crack bearing support when installing bearing and retainer)*

5) Mount pinion retainer assembly in Fixture T57L-500-A (Ford) and using Tool T57L-4851-B (Ford), 4851-G (Mercury), remove pinion shaft nut and washer Re-

CONTINUED ON NEXT PAGE

EDSEL, FORD, MERCURY "DEEP-OFFSET" HYPOID (C ntinued)

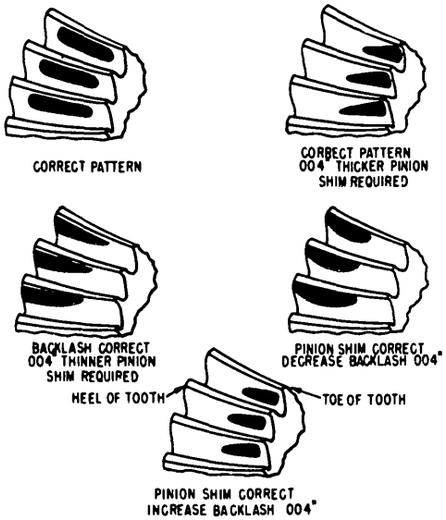
move universal joint flange, oil seal and slinger. Remove pinion retainer from fixture, place a protective sleeve (use a piece of hose or wrap with tape) on pinion pilot bearing surface, and press pinion shaft out of front bearing cone. Remove spacer. *CAUTION - Do not reuse this spacer.*

6) Install pinion shaft assembly in Tool T57L-4614-A and T57L-4621-A (Ford), 4621-K (Mercury), and press pinion out of rear bearing cone. *(NOTE - Do not remove pinion b aring cups from retainer unless cups or bearings are to be r placed).* If it is necessary to remove cups, press cup from retainer with Tool T57L-4616-A1 (Ford), or remove cups with Tool 4615-D (Mercury). To install cups, use same tools as for removal (Ford), press cups into position with Tool 4615-E (Mercury). *NOTE* - After cups installed, make sure they are solidly seated in retainer by attempting to insert a .0015" feeler between cup and bottom of bore in retainer.

INSPECTION: Clean all parts thoroughly with cleaning solvent. Oil bearings immediately to prevent rusting. Check pinion and ring gear teeth for scoring or signs of excessive wear. Check bearing cups for rings, scores or galling, or erratic wear pattern. Make sure cups are solidly seated in bores. Check bearing rollers for pits, scoring, or roughness. Install bearing caps temporarily and test the fit of adjusting nuts in their threads. Nuts should turn freely when caps are tightened to specifications. Face of adjusting nuts must be smooth and square. If necessary, polish with a fine abrasive on a flat surface. Check end of universal joint flange that contacts oil slinger. This surface must be smooth. Polish if necessary. Inspect pinion retainer for damage and make sure bearing cups are solidly seated. Clean burrs and chips from ring gear mounting flange. Clean grooves for "0" ring seal and clean all lubricant passages. Inspect carrier housing for damage, making sure threads are not damaged and that bearing bores are smooth. Remove nicks and burrs from mounting surfaces of carrier housing. Check bearing mounting hubs in differential for smoothness. Check fit of differential gears in counterbores. Inspect thrust surfaces for damage that might have occurred when bearing was removed.

REASSEMBLY: Diff r ntial Case *(NOTE - Lubricate all parts with r ar axl lubricant as they are assembled).* Place a side gear and thrust washer in differential case bore, then using a soft hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear. Place second pinion and thrust washer in position, then drive pinion shaft into place, being careful to line up pinion shaft retainer holes. Place second side gear and thrust washer in position and install cover of differential case. Install pinion shaft retainer pin. *(NOTE* - Check for free operation of the assembly by inserting a pinion or axle shaft spline in side gear spline, and rotating the assembly). Insert two 7/16" x 2" (N.F.) bolts through differential flange and thread them three or four turns into ring gear as a guide in aligning ring gear bolt holes. Press or tap ring gear into position. Install and tighten ring gear attaching bolts evenly and alternately across gear to 60-65 ft. lbs. If differential bearings have been removed, press them on hubs using Tool T57L-4221-A (Ford), 4222-K (Mercury).

Pini n & Retain r: Install pinion rear bearing cone on pinion shaft using Tool T57L-4614-A and T57L-4621-B (Ford), 4621-L (Mercury), then install a new spacer on shaft. Place bearing retainer on shaft and install front bearing cone, pressing it into place with same tools used for rear cone *(CAUTION - As bearing is pressed into position, rock pinion retainer. Do not press bearing on shaft until all "play" is removed between pinion retainer and bearings as spacer may be compressed too much).* Lubricate both bearings with rear axle lubricant. Place slinger in position, coat outside of new oil seal with an oil resistant sealer and press seal into bearing retainer using Tool T57L-4676-A (Ford), 4676-C (Mercury). *(NOTE - It is not necessary to soak a new Ford or Mercury seal in oil before installation as they are prepared at the factory for immediate installation).* Install universal joint flange and flat washer. Start pinion shaft nut. Adjust pinion bearing preload (see below). *(NOTE - If a new ring gear and pinion, or rear axle assembly housing is being installed, or the tooth contact pattern is not correct, see "Pinion Setting" and "Tooth Contact Pattern" below before further reassembly).*



Carrier Assembly: 1) Lubricate the "0" ring seal with rear axle lubricant and install it in its groove in pinion retainer being careful not to twist the seal. Place correct shim on carrier and install pinion and retainer assembly. Install pinion bumper and retainer bolts and tighten bolts to 35-40 ft. lbs.

2) Wipe a thin coating of lubricant on bearing bores. Place cups on the bearings and set differential case in carrier. Slide the assembly along bores until a slight amount of backlash is felt between gear teeth. Set adjusting nuts in bores so they just contact bearing cups *(NOTE - Each cup should be engaging approximately the same number of threads).* Carefully position bearing caps on carrier, matching the marks made at disassembly. Install bearing cap bolts and tighten alternately to 75-80 ft. lbs. Adjust gear backlash (see below). Install adjusting nut locks and tighten to 12-15 ft. lbs.

DIFFERENTIAL CARRIER ASSEMBLY INSTALLATION: Install carrier assembly in rear axle housing and tighten attaching nuts to 35-40 ft. lbs. Install axle shafts *(CAUTION* - Axle shafts are not the same length and are not interchangeable), wheels, and tires. Fill axle assembly with lubricant until level with filler plug hole.

PINION BEARING PRELOAD ADJUSTMENT: Hold retainer flange and tighten pinion shaft nut until the torque required to turn pinion shaft, as determined by Torque Indicator 4610-N and 4858-N (Ford), 4209 (Mercury), is 8-12 **inch pounds** (used bearings), 17-27 **inch pounds** (new bearings). *(NOTE - A minimum tightening torque of 175 ft. lbs. should be required on pinion shaft nut in order to obtain correct pinion bearing preload).*

PINION SETTING (Shim Selection): *(NOTE* - Differential carrier assemblies are manufactured to require a .015" pinion setting shim. If a new carrier assembly is being built up, a .015" shim should be used tentatively, and then adjusted in relation to tooth contact pattern). Adjusting shims are available in .010" to .021" thicknesses in steps of .001". Matching marks are placed on edge of

TYPICAL GEAR TOOTH PATTERN (DRIVE SIDE)

ring gear and on face of pinion gear *(CAUTION - Mak sure that both ring gear and pinion have the same matching marks, usually a three digit numeral).* A plus (+) or minus (−) digit, or an "0" (indicating a standard pinion gear) is placed on the pinion gear following the matching number to indicate pinion setting shim requirements as follows: A minus (−) number means that the pinion should be moved closer to the ring gear, and a thinner shim is required. A plus (+) number means the pinion should be moved farther from ring gear, and a thicker shim is required. A pinion marked zero (0) is a standard pinion. To select a shim, measure original shim with a micrometer. Then note dimensional mark on original pinion. Compare the mark on original pinion with mark on new pinion to determine how the original shim should be modified (Example: Original shim is .015", original pinion is marked −1, and new pinion is marked +1. The new pinion would require a .002" thicker shim. Therefore a .017" shim must be used). If new pinion is marked the same as the old pinion, no shim change is required.

GEAR BACKLASH ADJUSTMENT: With differential case installed in carrier, and with adjusting nuts, bearing caps, and bearings in place (see "Carrier Assembly" above), loosen the bearing cap bolts from a fully tightened position, then tighten them to only 20 ft. lbs. before making adjustments. Loosen adjusting nut on pinion gear (right hand) side until it is away from cup. Tighten nut on ring gear side (left hand) until the ring gear is just forced into pinion with no backlash (recheck right hand nut to make sure it is still loose). Tighten the right hand nut two notches beyond the position where it first contacts the bearing cup. Rotate ring gear several revolutions in each direction while the bearings are loaded, to seat bearings in cups *(CAUTION - This step is very important to insur prop r s ating of bearings).* Again loosen right hand nut to release the preload. If there is

CONTINUED ON NEXT PAGE

EDSEL, FORD, MERCURY "DEEP-OFFSET" HYPOID (C ntinu d)

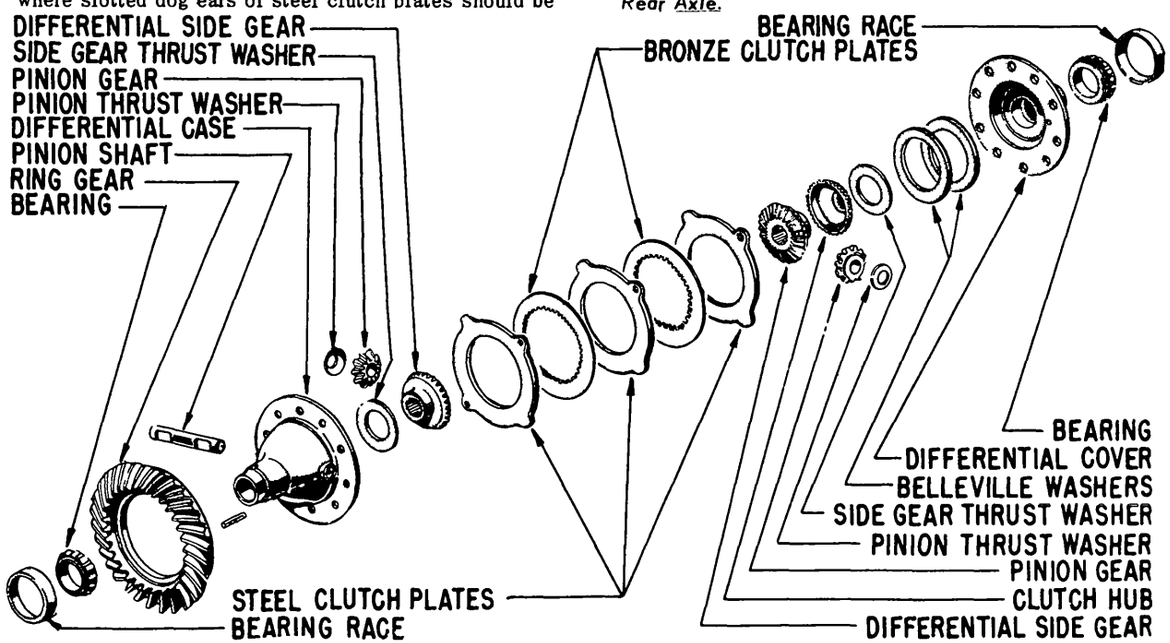
any backlash between gears, tighten left hand nut just enough to remove this backlash. Carefully tighten right hand nut until it just contacts bearing cup, and continue to tighten 2½ to 3 notches. Install dial indicator on carrier so that contact tip of indicator bears against face of a gear tooth on outer diameter of ring gear. Measure backlash which should be .004-.009". Repeat this measurement at several other teeth around ring gear. If measurements vary more than .003", there is excessive runout in gear or mounting. If backlash is not within specification of .004-.009", loosen one adjusting nut and tighten opposite nut an equal amount to move ring gear away from or toward pinion. *(NOTE - When moving the adjusting nuts, the final movement should always be made in a tightening direction. For example, if left hand nut had to be loosened one notch, loosen the nut two notches, then tighten it one notch).*

GEAR TOOTH CONTACT PATTERN: With completed carrier assembly mounted in a holding fixture, coat gear teeth with a suitable gear marking compound such as red lead and oil. Wrap a cloth around drive pinion to act as a brake, then rotate ring gear back and forth until a clear pattern is obtained. If tooth pattern is not correct, as indicated in the tooth pattern illustration, make the necessary adjustments for backlash and pinion position. *(NOTE - Tooth patterns in th illustrati n ar typical and are not characteristic of any n gear).*

EDSEL, FORD, MERCURY EQUA-LOCK DIFFERENTIAL

Edsel All Models (1958-60)
Ford Pass. Cars (1959-60)
Mercury All Models (1958)

►*WHEEL BALANCING CAUTION:* Do not use on-the-car type wheel balancers on models equipped with this type differential.



DESCRIPTION: Constant friction type differential assembly having three steel clutch plates locked into the differential cover, and two bronze bonded clutch plates splined to a clutch hub which, in turn, is splined to the left hand axle shaft. Two belleville spring washers maintain a constant pressure between the steel and bonded plates so that clutch is always engaged. The pressure of the clutch plates opposes differential action at all times. When the car is turned the clutch slips, allowing normal differential action to take place. With one wheel on a low traction surface, friction between clutch plates will transfer a portion of usable torque to the wheel with most traction, thus the wheel on the low traction surface will have a tendency to operate with opposite wheel in a combined driving effort.

►*REAR AXLE ASSEMBLY OVERHAUL NOTE:* Except for disassembly and reassembly of differential case, overhaul procedures are the same as for the standard axle. *See "Ford (Deep-Offset) Hypoid" Rear Axle.*

DISASSEMBLY: With differential assembly removed from rear axle housing, mark ring gear, differential case, and differential cover with paint or a scribed line to insure reassembly of all parts in the same position. Remove differential side bearings with a suitable puller. Alternately loosen bolts attaching ring gear to differential case until spring pressure has been decreased enough to prevent stripping threads from capscrews. *NOTE - A Hydraulic press may be used to reduce spring tension while capscrews are being removed. Apply approximately one ton pressure between case hubs and remove ring gear capscrews.* Remove cover from carrier, then remove ring gear. Remove steel dog-eared clutch plates and bonded clutch plates from cover. Remove two bellville spring washers, then remove differential clutch hub, side gear and thrust washer. Drive out differential pinion shaft lock pin, then drive out pinion shaft and remove gears and thrust washers.

INSPECTION: Check clutch plates for uneven or extreme wear. Dog-eared clutch plates must be free of nicks, scratches or burrs. Internally splined clutch plates should be checked for condition of bonding material and wear. Replace bonded plates if thickness is less than .085" or if material is scored or badly worn. Examine all thrust surfaces and hubs for wear. Inspect belleville washers for proper bevel. Free height should be .258".

REASSEMBLY: *NOTE - When reassembling differential, lubricate all parts liberally with Ford Lubricant, Part No. B9A-19580-A as they are installed.* Install side gear and thrust washer in differential case, then using a soft hammer, drive pinion shaft into case far enough to retain a pinion thrust washer and pinion gear. Place the second pinion and thrust washer in position and drive pinion shaft into place. *CAUTION - Carefully line up pinion shaft retainer holes.* Install pinion shaft retainer making sure it does not extend beyond machined surface of case. Insert two 2" x 7/16" (N.F. Threads) bolts through differential flange and thread them three or four turns into ring gear as a guide to aligning ring gear bolt holes. Press or tap ring gear into position. Clamp differential case in soft jawed vise, then install the second differential side gear on differential pinion gears and install clutch hub on side gear. Install thrust washer on clutch hub. Insert two 3/16" x 2" dowel pins into differential case (holes are provided at points where slotted dog ears of steel clutch plates should be located), then place a steel plate on differential case so slots in dog ears straddle dowel pins. Place a bonded plate on steel plate, making sure that inner splines of plate engage hub spline. Assemble remaining plates: a steel plate, a bonded plate, and finally a steel plate. Place two bellville springs on the top steel plate (concave side of washers should be down). Install differential case cover over dowel pins onto differential case, then start the ring gear bolts. Tighten bolts evenly and alternately across diameter of ring gear to compress springs and pull cover and differential case together. Tighten differential case-to-ring gear bolts to 65-75 ft. lbs., then remove aligning dowel pins. Install Tool T59P-4204-A1 and T59L-4204-A2 (Ford), Tool 44211 and 44211-A (Edsel in differential side gear splines and mount the complete assembly in a vise. Use a torque wrench and check torque required to rotate one side gear while the other is being held. The torque required to keep it turning should be 155-195 ft. lbs. If torque is not within these limits, check for improper reassembly. Complete reassembly of rear axle, *see "Edsel, Ford, Mercury (Deep Offset) Hypoid" Rear Axle.*

EDSEL, FORD & MERCURY EQUA-LOCK DIFFERENTIAL ASSEMBLY

Form 51 A

FORD TRUCK HYPOID "SPLIT HOUSING" TYPE

F-250 All Models (1954-Early 1955)
F-350 Parcel Delivery (1954-Early 1955)

►*NOTE:* "Ford, Lincoln, Mercury Hypoid (Integral Carrier)" Rear Axle used beginning Late 1955.

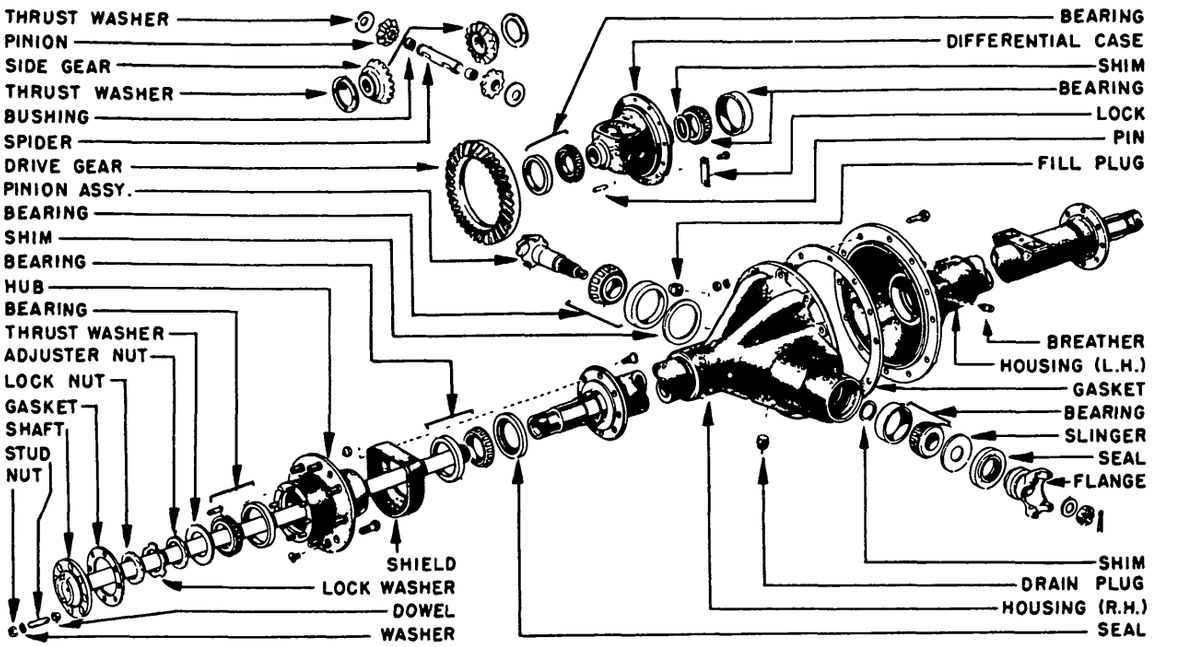
DESCRIPTION: Full-floating hypoid gear type with Hotchkiss drive. Axle housing is of split type, each half consisting of a steel tube riveted into a cast housing. Rear spring seats are welded to tops of axle housing tubes. Outer ends of tubes are machined for installation of wheel bearings and are threaded for installation of wheel bearing adjusting nuts. Flanges, forged integral with housing tubes, provide facilities for installation of brake carrier plates. Differential side bearing cups are pressed into machined bores in axle housing. Differential case is single piece type with two pinion gears.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: This work can be done without removing wheels and hubs, as follows:

Axle Shaft Removal—Drain lubricant from housing, remove axle shaft stud nuts and washers. Tap center of axle shaft flange to loosen tapered dowels, and remove the dowels. Remove axle shaft and gasket from housing.

Axle Shaft Installation—Install brake carrier plate, then hub and drum assembly, place new gasket on hub. Insert axle shaft in housing, lining up shaft splines with differential side gear splines. Install tapered dowels, lockwashers, and nuts on studs. Tighten nuts to 50-70 ft. lbs. torque.



Wheel Bearing Adjustment—Remove axle shaft (above), bearing locknut and washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt, then back off adjusting nut ⅛ turn. Install bearing lock washer and locknut, and bend one tab of lock washer over adjusting nut and one tab over locknut. Install axle shafts.

OVERHAUL: Before disassembling axle, check drive gear backlash and record the reading for reference when reassembling axle. *See "Backlash Checking & Adjusting (below).*

Disassembly: Remove wheels, axle shafts (see "Axle Shaft Removal" above). Remove hub and drum assemblies and brake backing plates.

Differential Removal—Insert a piece of pipe slightly smaller than axle shaft splines, approximately two-thirds way through housing from the differential case side to prevent differential assembly from dropping. Remove nuts, washers, and bolts securing the two halves of axle housing together, and separate the axle housing. Remove differential assembly and pipe from housing. Remove differential side bearing cups from housing with Tool T53T-4222-A.

Differential Disassembly—Mark ring gear and differential case to insure reassembly in same position. Remove bolts and lock plate holding ring gear to differential case and remove the gear. Remove lock pin securing spider shaft in differential case with a long pin punch, then remove spider shaft, pinions, side gears and thrust washers. Remove differential side bearings with Tool T53T-4242-F (Be sure the side bearing cups are clamped in place over bearings when using the tool). Remove side bearing shims.

FORD TRUCK "SPLIT HOUSING" HYPOID AXLE

Drive Pinion Disassembly—Remove drive pinion shaft cotter pin. Hold universal joint with Tool T53T-4851-E, and remove nut and washer from drive pinion shaft. Remove flange from drive pinion shaft with Tool T53T-4851-A. Remove drive pinion from axle housing by rotating shaft while driving it from housing with a soft hammer. Remove drive pinion oil seal, oil slinger, and drive pinion outer bearing from housing. Remove outer bearing cup with Tool T53T-4621-A. Tap inner bearing cup and adjusting shims from axle housing with a soft drift. CAUTION—Measure and note thickness of shims found behind inner bearing cup. Remove the pinion bearing shims from pinion shaft, then press inner bearing from shaft with Tool T53T-4629-A.

Reassembly & Adjustment: Inspect gear teeth, bearings and bearing cups for signs of galling, pitting or wear, and replace any parts found to be defective. Clean all parts and blow dry with air.

Differential Reassembly—Lubricate all differential parts with gear lubricant, then position the thrust washers and pinion gears in case, and install differential side gears and differential spider. Install the lock pin that secures spider to differential case, and stake the lock pin in place. Align the marks (made at disassembly) on drive gear and differential case, then position drive gear on case. Be sure drive gear is properly seated, then install bolts and lock plates securing gear to case. Tighten bolts to 40-50 ft. lbs. torque. Press differential side gears on case with Tool T53T-4221-A, and arbor press. *(CAUTION—Do not install bearing shims at this time).* Install differential side bearing cups in each half of axle housing, using Tool T53T-4242-B (left side), and Tool T53T-4242-A (right side).

Differential Side Bearing Preload Adjustment—Position differential assembly in housing, using a piece of pipe to support assembly. Place new axle housing gasket on housing flange, then bring housing halves together. Install alternate housing bolts, washers, and nuts, and tighten bolts to 20-26 ft. lbs. Install a dial indicator on left-hand axle housing so that indicator stem enters access hole and contacts back face of drive gear. Push drive gear from side to side to check differential endplay. Rotate drive gear to several positions, and check endplay at each position. Remove differential from housing, and add shims behind side bearings necessary to bring differential preload within range .001-.005" (.003" preferred). *(NOTE*—Shim thickness should be equal to endplay plus .003".) Split shim pack equally and install shims behind both side bearings. Install differential in axle housing, and tighten alternate bolts to 20-26 ft. lbs. Install dial indicator stem against back face of drive gear. Rotate drive gear and recheck the runout. Maximum drive gear runout is .005".

Drive Pinion Assembly—Press the inner bearing on drive pinion shaft, using Tool 4615-A and arbor press.

Drive Pinion Installation—Position the original

CONTINUED N NEXT PAGE

FORD TRUCK HYPOID "SPLIT HOUSING" (C nt.)

shims in axle housing, then install inner and outer bearing cups with Tool T53T-4616-A. Install shims on pinion shaft, then position pinion in axle housing. Install outer bearing on pinion shaft with Tool T53T-4261-A. Install universal joint flange with Tool T53T-4851-B. Hold flange with holding tool, then install flange nut and washers. Tighten nut to 200-250 ft. lbs. torque.

Pinion Bearing Preload Check—(With Differential Assembly Removed). Wrap a heavy twine several turns around shank of companion flange and attach scale Tool 6110-A. By pulling horizontally on scale check torque required to rotate assembly. If torque is not within 12 to 18 inch pounds, remove pinion shaft and add or remove shims from pinion shaft to bring torque within specified limits. Removing shims INCREASES torque, adding shims DECREASES torque. Reassemble pinion and recheck preload.

Differential Installation & Adjustment—Paint 12 drive gear teeth with red lead.. Insert pipe, used in axle disassembly, through housing half, then position differential assembly in housing. Install axle housing gasket, and bring both housing halves together. Install alternate bolts and nuts, then tighten bolts to 20-26 ft. lbs. torque. Install a dial indicator so contact arm rests against pinion shaft companion flange (on long side, opposite center of bolt hole) and check backlash between drive gear and drive pinion teeth. Rotate companion flange away from indicator until contact between gear teeth is felt. Set dial indicator at zero, rotate the flange against contact stem until all backlash is removed, then note reading on indicator. This reading will be exactly 1½ times the amount of backlash between gears. The correct lash is .008-.013" (dial indicator will read .012-.020"). If backlash is not within limits, add or remove shims behind pinion inner bearing cup until correct backlash is obtained.

Check Gear Tooth Contact—Insert axle shafts in housing. Hold axle shaft to impose a load on the gears, and turn universal joint flange several times in both directions to obtain tooth pattern. Disassemble axle and check tooth contact pattern (pattern should be fairly well centered on tooth, and slightly toward inner diameter, with ends of tooth not indicating a contact pattern). Add or remove shims from behind drive pinion inner bearing cup to correct depth for proper tooth pattern (CAUTION—Add or Remove the same amount of shims from pinion shaft outer bearing so pinion bearing preload will not change). When correct tooth pattern obtained, install remaining bolts, washers and nuts, and tighten nuts to 20-26 ft. lbs.

Drive Pinion Oil Seal Installation—Remove the universal joint flange after completing preload, ring gear tooth pattern, and backlash checks. Place oil slinger on pinion shaft, then install drive pinion oil seal with Tool T53T-4676-A. Install flange, washer and nut and tighten nut to 200-250 ft. lbs. torque. Install cotter pin.

FORD TRUCK HEAVY DUTY "SPLIT HOUSING" HYPOID

F-350, Exc. Parcel Delivery (1954-55)

DESCRIPTION: Hypoid gear type with full floating axles and Hotchkiss drive.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: It is not necessary to remove wheels and hubs.

Axle Shafts—Remove axle shaft stud nuts and lock washers. Turn two shaft pulling bolts (located between stud hole) in evenly to loosen axle shaft from hub. Tap axle shaft in center of flange to loosen dowels and remove dowels. Pull shaft from housing. To install, place new gasket on hub and install axle shaft in housing, rotating axle to line up spline with splines in side gears. Install tapered dowels, lock washers and nuts on studs and tighten to 50-70 ft. lbs.

Wheel Bearing Adjustment—Remove axle shaft (above) bearing lock nut and lock washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt. Back off adjusting nut ⅛ turn. Install bearing lock washer (NOTE—If adjusting nut is equipped with a dowel, make sure lock washer fits over dowel). Install bearing lock nut and tighten. If flange type lock washer is used, bend one flange over adjusting nut and one over lock nut. Install axle shafts.

Wheel Bearing Assembly—To disassemble, remove axle shaft, adjusting locknut, washer and adjusting nut. Remove wheel hub. Tap out inner bearing cone and grease retainer. Bearing races may be tapped out, using a brass drift. To re-assemble, install inner bearing race and bearing cone, install oil seal. Install outer race and bearing cone. Install axle on hub and adjust bearings (see above).

RING GEAR BACKLASH: .006-.012". Adjustment by shims behind bearing cups in axle housing.

OVERHAUL OF REAR AXLE ASSEMBLY:

Disassembly: Remove axle shafts and wheel hubs. Insert a length of pipe slightly smaller than axle shaft in left axle tube (facing front of truck) so as to engage differential case to prevent it dropping. Remove nuts and bolts from housing and separate it. Remove differential assembly, and pipe from housing.

Differential Disassembly—Mark differential case halves with a punch. Cut lock wires, remove nuts and separate case. Remove spider, pinions, side gears and thrust washers. Remove differential bearings using Tool 4221-K. Centerpunch rivet heads and drill through heads with a drill 1/32" smaller than rivet body. Press rivets out and remove ring gear. Using a suitable puller, remove bearing cups from each side of axle housing. *(CAUTION*—Keep spacers found behind each cup together, and wire them to their respective axle housing half).

Drive Pinion Cage Assembly Removal—Hold universal joint flange with Tool 4851, and remove nut and washer from pinion shaft. Use a suitable puller and remove universal joint flange. Remove drive pinion bearing cover and oil seal assembly. Remove drive pinion and cage assembly, using puller screws in holes provided in cage.

►*CAUTION—Do not drive pinion from inner end as this will damage bearing lock ring groove.*

Drive Pinion and Cage Disassembly—Tap or press drive pinion from cage assembly. Remove outer bearing from cage and remove spacer or spacer combination from pinion. On F-350 Trucks, remove drive pinion rear bearing with Tool T53T-4242-F, then remove pilot bearing snap ring from inner end of drive pinion. Position pinion in press and remove pilot bearing.

Reassembly of Rear Axle:

Drive Pinion Cage Reassembly—Press pilot bearing on end of pinion shaft, using a sleeve to apply pressure evenly to bearing inner race. Install snap ring and press into groove securely. Install bearing cups in bearing cage and press to seat them on cage shoulders. Lubricate bearings and cups with light oil and install rear bearing on pinion shank and insert drive pinion and bearing assembly in bearing cage. Install spacer or spacer combination on pinion shank and press front bearing firmly against spacer.

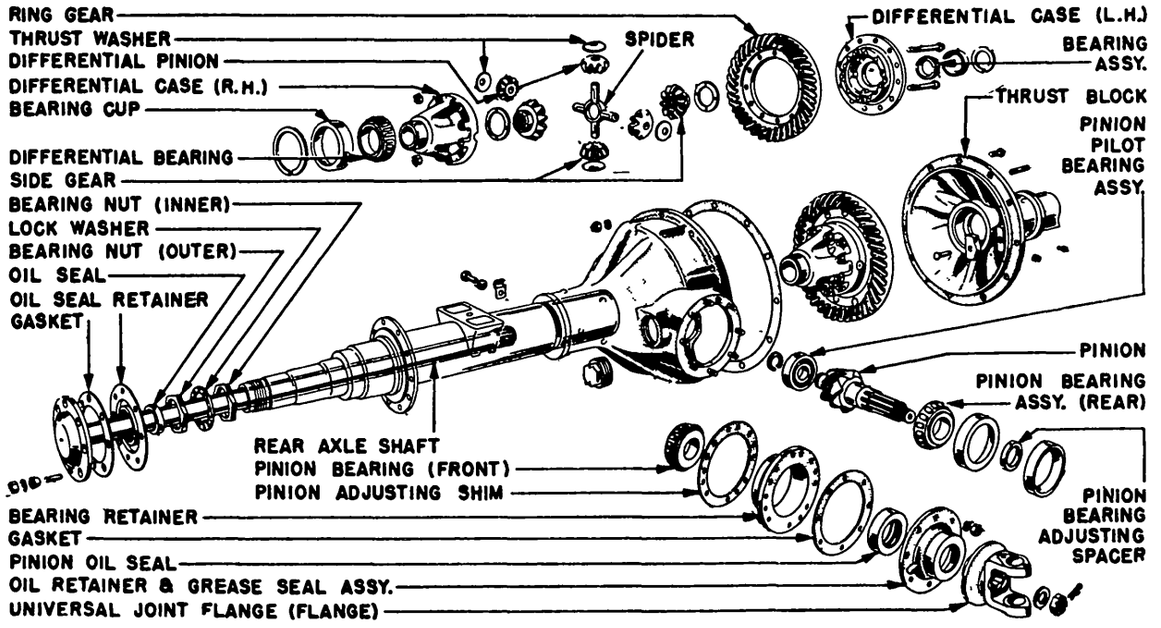
Drive Pinion Bearing Pre-Load Check—Install a sleeve on drive pinion shank that will apply pressure to pinion bearing inner race. Place pinion and cage assembly in a press and apply 25,000 lbs. pressure on the bearing. Wrap a soft wire around the cage and attach a pound-pull scale to wire. Pull on the scale on a horizontal line. It should require 12-18 inch lbs. to keep the cage rotating. If rotating torque is not between 12-18 inch lbs., install a thinner spacer to increase or a thicker spacer to decrease the pre-load. If a press is not available, the yoke may be installed and the pinion nut tightened to 300-400 ft. lbs., for checking the pre-load. After preload is checked and is satisfactory, install new oil seal in drive pinion bearing cover, using Tool 1175-D (F-6). Tool T53T-4676-B (F-350). *(NOTE—Soak new seal in oil at least one-half hour before installing).* Install drive pinion bearing cover, yoke, nut, and washer. Tighten nut to 300-400 ft. lbs. and install cotter pin.

Differential Reassembly—Position ring gear on case, making sure it is tight on case pilot. Install rivets and upset them cold. Head should be ⅛" larger than rivet hole, after forming Formed head of rivet should be at least 1/16" smaller in diameter than performed head. Excess pressure will distort case and result in gear eccentricity. Lubricate all parts with gear lubricant. Position a thrust washer and side gear in ring gear half of differential case assembly. Place spider with the pinions and thrust washers in position on the side gear. Install remain-

CONTINUED ON NEXT PA E

FORD TRUCK HEAVY DUTY "SPLIT HOUSING" (C ntinu d)

ing side gear and thrust washer. Align marks on each half of case and place two halves together. Install the bolts and nuts and tighten to 80-110 ft. lbs. Lock nuts with lock wire. Install differential case bearings, using a press or suitable driver.



Differential Bearing Pre-Load Adjustment—Remove thrust block from housing. Install differential bearing cups and spacers in their original position in differential housing. *(CAUTION—Install spacers with chamfered edge toward machined surface in housing).* Insert pipe used in disassembly through the housing half. Place differential and gear assembly over the pipe and slide assembly into position in housing. Install new flange gasket and position the other half of housing half in place and secure the two halves together with 6 bolts evenly spaced. Install dial indicator on housing so that dial shaft extends through thrust block pin hole and contacts ring gear. Using two screw drivers, check differential assembly end play. Should be 0.000-0.005".

NOTE—Both the differential bearing pre-load and gear lash ar controlled by selective spacers, available in .004" thickness, which are installed between bearing cups and axle housing halves).

It is necessary to separate the housing halves and remove the differential bearing cups each time spacer thickness is changed. The gear may be moved toward the pinion, to decrease gear lash, by decreasing spacer thickness in case half and increasing spacer thickness in cover half. Reversing this procedure will move gear away from pinion to increase gear lash. (IMPORTANT—Increase or decrease thickness of spacer used in COVER half of housing to obtain a free rotating gear with from .000-.005" end play. AFTER END PLAY HAS BEEN ESTABLISHED, add spacer to equal .008" PLUS THE END PLAY). After endplay has been established, separate axle housing and move differential assembly out on support far enough to permit installation of drive pinion and cage assembly. Install the thrust block.

Pinion Cage Installation—Position drive pinion and cage assembly on rear axle housing studs and tap cage into place with soft hammer. Install lock washers and stud nuts or capscrews. Tighten to 70-90 ft. lbs. (F-6). 25-30 ft. lbs. (F-350).

Gear Backlash Check—After correct preload has been established, install six bolts evenly spaced in housing and tighten to 85-95 ft. lbs. Install a dial indicator so indicator shaft will rest on one side of universal joint yoke approximately 2" from centerline of pinion shaft. Check movement for backlash. The amount indicated at this point will be double the actual amount. Shift the spacer used in back of the differential bearing cups in axle housing, DECREASING the thickness of spacer used, on side TOWARD which gear is to be moved, and increasing the thickness of the opposite spacer EXACTLY the same amount as required to obtain a backlash of .006-.012" (dial will read .012-.024"). After correct backlash is obtained, install remaining housing bolts and tighten to 85-95 ft. lbs.

FORD TRUCK HEAVY DUTY "SPLIT HOUSING" HYPOID AXLE

1954-55 FORD TRUCK HYPOID "BANJO HOUSING" TYPE

Ford Truck, 500 & 600 Series (1954-55)

►*NOTE—Different axle assemblies used for each series. Except for minor structural differences and variation in size of parts; the two axle assemblies are identical. The service procedures apply to both assemblies unless otherwise noted.*

DESCRIPTION: Full-floating, hypoid gear type with Banjo Type housing and Hotchkiss drive.

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: This work can be done without removing wheels and hubs, as follows:

Axle Shafts—Drain lubricant from housing, then remove axle shaft stud nuts and washers. Tap center of axle shaft flange to loosen tapered dowels, and remove the dowels. Remove axle shaft and gasket from housing. To install, place new gasket on hub and install axle shaft in housing, rotating axle to line up axle splines with splines in gear. Install tapered dowels, lock washers, and nuts on studs and tighten to 50-70 ft. lbs torque.

Wheel Bearing Adjustment—Remove axle shaft (above), bearing locknut and washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt, then back off adjusting nut ⅛ turn. Install bearing lock washer and lock nut, and bend one tab of lock washer over adjusting nut and one tab over locknut. Install axle shafts.

►*OVERHAUL NOTE—Axle assemblies are different for the F-500 & F-600 Trucks, in parts sizes and structural variation.*

OVERHAUL (1954-55 500 SERIES, 1954 600 SERIES): The following service procedures apply to both series trucks except where noted. *See "Overhaul (1955-600 Series)" below for differences which apply to the lat r 600 Series Rear Axle.*

Disassembly: Remove wheels, axle shafts (see "Axle Shaft Removal" above). Remove hub and drum assemblies and brake backing plates.

Differential Carrier Removal—Support carrier assembly with a roller jack and remove carrier-to-housing nuts and lockwashers. Tighten the puller screws provided in carrier, until carrier is loosened from housing. Carefully withdraw carrier assembly from axle housing, then back off puller screws. Remove and discard axle housing gasket. Position carrier in transmission stand or on open end of oil drum, for further work.

Differential Carrier Disassembly—Loosen thrust block screw (used on Series F-500 only), then back out thrust screw to provide clearance between thrust block and ring gear, when differential is removed. Mark differential bearing caps and carrier legs to insure reassembly in same position. Remove the adjuster locks, bearing cap bolts and caps. Remove side bearing adjuster, then lift differential assembly out of carrier. Remove ring gear thrust block from carrier.

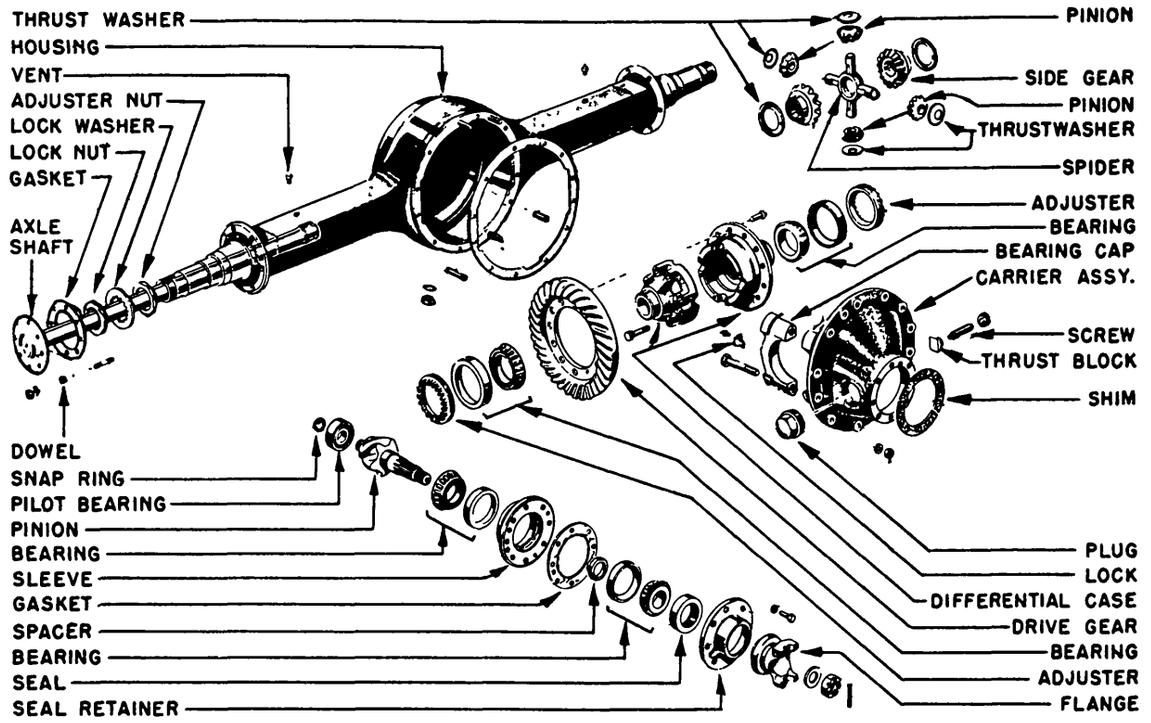
Differential Disassembly—Clamp assembly in a vise equipped with brass jaws, then remove differential side bearings. *(CAUTION—Make sure bearing cap is clamped tightly on bearing)* with Tool T53T-4242-F. Mark the differential case halves with a punch to insure aligning case when reassembling. Cut the

CONTINUED ON NEXT PAGE

1954-55 FORD TRUCK HYPOID "BANJO HOUSING" TYPE

lock wires and remove differential case bolts and nuts (F-600), or cap screws (F-500). Separate case halves, using a brass hammer if necessary, then remove side gears, spider, pinions and thrust washers. Center punch the drive gear rivet heads and then drill through the rivet heads using a drill 1/32" smaller than rivet body. Press out the rivets, then tap drive gear off case with a soft hammer.

Drive Pinion Removal—Hold universal joint flange with Tool T53T-4851-E, then remove cotter pin, nut and washer from drive pinion shaft. Remove flange with Tool T53T-4851-A. Remove nuts or bolts and lockwashers attaching oil seal retainer and pinion bearing sleeve to differential carrier. Remove pinion and sleeve from carrier with a soft hammer.



Drive Pinion Disassembly—Remove pinion bearing sleeve shims noting quantity and thicknesses used. Remove oil seal retainer. Remove universal joint flange thrust washer (F-600). Remove front pinion bearing and spacer from sleeve. Tap or press drive pinion out of bearing sleeve. Press drive pinion rear bearing off shaft with Tool T53T-4242-F. Remove pilot bearing snap ring, then remove pilot bearing with Tool T53T-4625-A and arbor press. Remove pinion bearing cups from sleeve.

Reassembly & Adjustment: Inspect gear teeth, bearings and bearing cups for signs of galling, pitting or wear, and replace any parts found to be defective. Clean all parts and blow dry with air.

Drive Pinion Reassembly & Preload Adjustment—Press drive pinion pilot bearing on pinion, then install snap ring. Press pinion rear bearing on shaft until seated against back face of pinion gear. Press pinion bearing cups in sleeve, then insert drive pinion, and install pinion bearing spacer. Install front bearing in sleeve.

Preload Checking & Adjustment—Install a sleeve on the pinion shank that will apply pressure to pinion inner race. Place drive pinion and cage assembly in a press and apply 25,000 lbs., pressure on bearing. Wrap a soft wire around cage and attach a pound pull scale to wire. Pull on scale in a horizontal line and note pull required to keep cage rotating. If rotating torque is not between 12 to 18 inch lbs., install a thicker washer to decrease or thinner washer to increase the preload. (NOTE—If a press is not available, install the universal joint flange, tighten nut to 300-350 ft. lbs., then check the preload. After correct preload has been obtained, remove universal joint flange).

Installation in Carrier—Install a new oil seal in drive pinion bearing cover with Tool T53T-4676-B (F-500), or Tool T53T-4676-C (F-600). ***(NOTE—Soak new oil seals in oil for one-half hour before installation).*** Position the universal joint flange thrust washer (F-600 only), bearing cover, universal joint flange, washer and nut on drive pinion. Hold flange with holding tool and tighten nut to 300-350 ft. lbs. torque. Install cotter pin. Place the original pinion bearing shims on differential carrier, then place drive pinion and cage assembly in carrier. Tap assembly into place with soft hammer and install capscrews or nuts, and lockwashers. Tighten capscrews (F-500) to 25-30 ft. lbs., and tighten nuts (F-600) to 55-75 ft. lbs. torque.

FORD TRUCK "BANJO HOUSING" HYPOID AXLE

Differential Reassembly—Position drive gear on differential case, making sure that drive gear and differential case are clean, then rivet gear to case. Assemble pinions, side gears, spider, and thrust washers in drive gear half of differential case. Install other half of case, making sure the punch marks on case halves are aligned. Install differential case bolts and nuts (F-600) or capscrews (F-500). Tighten capscrews (F-500) to 45-50 ft. lbs., or nuts (F-600) to 95-105 ft. lbs. Install lock wires.

Differential Installation & Backlash Adjustment—Install thrust block screw in axle housing, then place thrust block on screw (F-500 only). Place side bearing cups over side bearings, then position differential assembly in carrier. Position bearing adjusters in carrier, making sure adjuster threads mesh with threads in carrier. Install bearing caps in their original position using alignment marks as guide. Tighten bearing cap bolts enough to hold adjusters snug but still permit rotation. Tighten adjusters hand tight against side bearing cups. Turn left hand adjuster until drive gear is loosely meshed with pinion gear. Mount a dial indicator so contact stem bears against back face of drive gear, then loosen right hand adjuster just enough to notice endplay on indicator. Tighten this adjuster until .000" endplay is obtained. Check drive gear runout. If runout exceeds .008" remove differential and check cause. TIGHTEN EACH ADJUSTER ONE NOTCH FROM .000" POSITION to preload differential bearings.

Backlash Adjustment—Mount dial indicator on carrier with contact stem of indicator bearing against face of one tooth on drive gear, then adjust drive gear to obtain .006-.012" backlash. To reduce the backlash, loosen right hand adjuster and tighten left hand adjuster the same number of notches. To increase, perform the same operation in reverse. Check pinion gear setting (below) and if correct, tighten bearing cap bolts to 80-100 ft. lbs. (F-500), or 120-140 ft. lbs. (F-600). Install adjuster locks, tighten lock bolts to 15-20 ft. lbs. torque, then install lock wires.

Pinion Gear Setting—Check gear tooth contact pattern by coating a number of ring gear teeth with red lead, and rotating the pinion shaft back and forth while maintaining a slight pressure on ring gear. Pressure pattern should be uniform and centered slightly toward inner side of tooth center. If adjustment is necessary, pinion position can be changed by varying thickness of shim pack between pinion cage and carrier.

Thrust Pad Adjustment (F-500)—Tighten thrust block screw until thrust block just touches drive gear. Back off screw at least 1/6 turn but not more than 1/4 turn to provide proper clearance between block and drive gear. Tighten thrust block lock screw while holding screw in this position.

CONTINUED N NEXT PAGE

1954-55 FORD TRUCK HYPOID "BANJO HOUSING" TYPE (Cont.)

Differential Carrier Installation—Place a new carrier-to-housing gasket on axle housing studs, making sure puller bolt holes in gasket are aligned with holes in housing. Place differential carrier on roller jack, then roll assembly into position. Start carrier into housing with four nuts evenly spaced. Tighten nuts alternately to draw carrier squarely into housing. Install remaining nuts and lockwashers and tighten nuts to 55-75 ft. lbs. torque.

OVERHAUL (1955 600 SERIES): Procedures for overhauling are the same as for 1954-55 500 Series, 1954 600 Series Rear Axles except as noted below

Disassembly: Differential Carrier Removal—Remove rear axle housing cover and gasket, then remove differential carrier from housing

Differential Dissassembly—Differential case halves are held together by capscrews.

Drive Pinion Disassembly—Grind peened portion off of drive pinion, then press pinion out of pilot bearing Remove pinion bearing cup from sleeve

Reassembly & Adjustment: Drive Pinion Reassembly & Preload Adjustment—Press pilot bearing on drive pinion, then peen or stake end of drive pinion to secure pilot bearing in place

Preload Checking & Adjustment—Rotating torque should be 18-25 in lbs

Installation in carrier—Install new felt grease seal with Tool T53T-4676-C. Make certain that gasket groove in face of pinion sleeve flange is clean, then install a new cork gasket, which has been soaked in water, in the groove Tighten capscrews to 25-30 ft. lbs Tighten nuts to 85-95 ft lbs

Differential Reassembly—Tighten differential case capscrews to 50-70 ft lbs

Differential Installation & Backlash Adjustment—Runout should not exceed .006".

Backlash Adjustment—Tighten bearing cap bolts to 160-175 ft lbs

Differential Carrier Installation—Install new cover gasket and cover with capscrews and new lockwashers Torque capscrews to 50-70 ft lbs.

1956-60 FORD TRUCK HYPOID "BANJO HOUSING" TYPE

F-350 (1956-60)
P-350, P-400 (1959-60)
B,C,F, P-500 & 600 (1956-60)

DESCRIPTION: Full floating, hypoid gear type with Hotchkiss drive

▷*REAR AXLE NOTE. Different model axle assemblies are used for the different model trucks Assemblies used on 1959-60 F-350 & P-400 Series trucks have a single type casting differential carrier (other series trucks have a multiple casting carrier) Service procedures apply to all assemblies unless otherwise specified*

▷*DIFFERENTIAL SIDE BEARING NOTE (Single Type Casting Differential Carrier) Right hand bearing and adjusting nut is larger than left hand bearing and adjusting nut. The larger right hand bearing cone has 19 rollers and the smaller left hand bearing cone has 22 rollers*

REMOVAL OF AXLE ASSEMBLY: *See "Rear Axle" on Truck Model pages.*

AXLE SHAFT REPLACEMENT: Drain lubricant from housing, then remove axle shaft stud nuts and washers. Tap center of axle shaft flange to loosen tapered dowels, and remove the dowels. Remove axle shaft and gasket from housing. To install, place new gasket on hub and install axle shaft in housing, rotating axle to line up axle splines with splines in gears Install tapered dowels, lockwashers and nuts on studs and tighten to 50-70 ft lbs

WHEEL BEARING ADJUSTMENT Remove axle shaft (see above), bearing locknut and washer Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt, then back off adjusting nut 1/8 turn Install bearing lockwasher and locknut and bend one tab of lockwasher over adjusting nut and one tab over locknut. Install axle shafts.

OVERHAUL: The following service procedures apply to all series trucks except as noted

Differential Carrier Removal: Remove axle shafts (see above). Support carrier assembly properly with a roller jack, then remove carrier to housing bolts and lockwashers. Tighten the puller screws, when provided in carrier, until carrier is loosened from housing. Carefully withdraw carrier assembly from axle housing, then back off puller screws Remove and discard axle housing gasket.

Differential Carrier Disassembly: Adjust differential bearing pre-load (if bearings are in good condition) then check runout of drive gear with a dial indicator Make a note of runout for reference during reassembly. On 500 Series trucks, loosen the thrust block locknut, then back out the thrust screw and block to provide clearance for drive gear. On all models, mark differential bearing caps and carrier legs with a punch as a guide when reinstalling bearing caps. Remove adjuster locks. Remove bearing caps and remove differential assembly from carrier Remove thrust block on 500 Series trucks.

Differential Disassembly: Clamp assembly in a vise with soft jaws, then remove differential side bearings with a suitable puller Mark differential case halves with a punch before disassembling, and remove bolts or cap screws Separate case halves, using a brass hammer if necessary, then remove side gears, spider, pinions and thrust washers. Center punch the drive gear rivet heads on drive gear end of rivets. Drill through the rivet heads using a drill 1/32" smaller than rivet body. Press out rivets, then tap drive gear off case with a soft hammer.

MULTIPLE CASTING CARRIER

Pinion Removal & Disassembly: Hold universal joint flange, then remove cotter pin, nut and washer from drive pinion shaft. Remove flange using Tool T53T-4851-A. Remove bolts which attach oil seal retainer and pinion bearing sleeve to carrier. Remove oil seal retainer then on 600 Series trucks, remove the universal joint flange spacer washer. Drive the drive pinion and sleeve assembly out of carrier, or remove it with puller screws. Remove pinion bearing sleeve shims, noting the number and thickness of shims used. Tie shim pack together and retain for future use Tap or press drive pinion out of the front pinion bearing and sleeve, then press the drive pinion out of spacer and rear pinion bearing. Remove pilot bearing snap ring, then remove pilot bearing with Tool T56T-4625-A (F-350), T53T-4625-A (F-500 & F-600). Remove pilot bearing snap ring and remove pilot bearing.

Pinion Reassembly & Adjustment: Press drive pinion pilot bearing on drive pinion, then install snap ring. Press rear bearing on shaft until seated against back face of pinion gear. Press pilot bearing cups in sleeve. Insert drive pinion into pinion bearing sleeve, then install old pinion bearing spacer for a trial build-up. Install front bearing in sleeve On 350 Series trucks, install universal joint flange and tighten flange nut to 175-250 ft. lbs. Wrap a strong cord or soft wire around the bearing cage and attach a pound-pull scale to cord. Measure the torque required to keep cage rotating (disregard torque required to start cage rotating). If torque required to keep cage rotating is not between 12-18 inch pounds, install a thinner spacer to increase or a thicker spacer to decrease the pre-load. This same procedure is used on 500 & 600 Series trucks, except that the universal joint flange nut is tightened to 300-400 ft. lbs. After pre-load is properly set, install a new oil seal in drive pinion seal in drive pinion seal retainer with Tool T53T-4676-B (350 & 500 Series); T53T-4676-C (600 Series). On 600 Series trucks, place the universal joint flange thrust washer on top of drive pinion outer bearing. Install oil seal retainer assembly, universal joint flange, washer and nut on drive pinion. Hold flange and tighten nut to 300-350 ft. lbs., then install cotter pin. Place original bearing cage shims on differential carrier, then place drive pinion and sleeve assembly into carrier and tap it into place with a soft hammer. Install cap screws and lockwashers, then tighten screws to 23-31 ft. lbs.

SINGLE CASTING CARRIER

Pinion Removal & Disassembly: With differential case assembly removed from rear axle housing, press pinion out of flange and pinion front bearing cone Remove pinion bearing preload shims from pinion shaft (or from front bearing cone) Remove pinion flange oil seal with Tool 1175-AE or 4676-N, then remove pinion bearing rear cup *NOTE - Use a micrometer and measure shim or shims which were found under pinion bearing rear cup* If pinion front bearing cup is to be removed, use a drift and drive it out of housing Press pinion rear bearing cone from shaft using Tool T53T-4629-A (4 86-1 ratio), T56T-4630-D (5 14-1 ratio), T56T-4630-E (5 83-1 ratio)

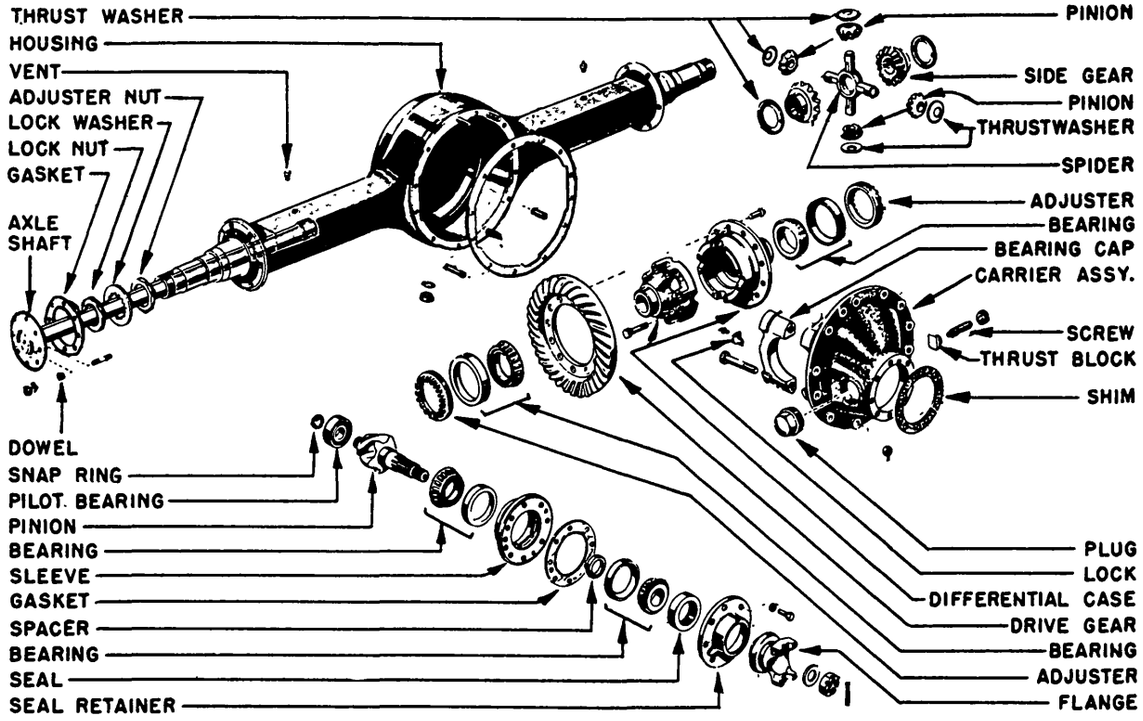
Pinion Setting: Pinion depth is adjusted by removing or installing shims located behind pinion rear bearing cup (between cup and carrier). *Increasing* the shim pack *decreases* pinion and drive gear assembled dimension. *Decreasing* the shim pack *increases* pinion and drive gear assembled dimension. When a new pinion and ring gear are installed, check the markings on both old and new pinion and adjust pinion locating shim pack ac-

CONTINUED ON NEXT PAGE

1956-60 FORD TRUCK HYPOID "BANJO HOUSING" TYPE (C nt.)

cordingly. A plus (+) marked pinion requires removal of shims in amount of the marking. A minus (−) marked pinion requires additional shims in amount of the marking. *NOTE - Before pinion is installed, check for a backlash marking which may be etched on pinion spline.*

Pinion Installation & Bearing Preload Adjustment: 1) Place pinion rear bearing cup shim pack in bore in carrier housing and press cup into case with Tool T53T-4616-B and an arbor press. Check installation of cup by trying to insert a .0015" feeler gauge under cup. If pinion front bearing cup was removed, install cup with Tool T53T-4616-D. If a new pinion is being installed, add or subtract from original pinion bearing preload shim pack, then same amount in thousandths of an inch that was added or subtracted from shim pack behind pinion rear bearing cup.



2) Place Tool T53T-44807-B on press bed with open end upward, then place pinion front bearing cone on tool with tapered rollers pointing upward. Center bearing on tool. Place carrier housing with front end down, on pinion front bearing cone (carrier housing is now resting on pinion front bearing cones and rollers). Hold housing in this position and start pinion shaft (with rear bearing cone and preload shims in place) into pinion front bearing cone. Lower ram of press and press pinion shaft into front bearing cone. As pinion shaft is pressed into position, rotate carrier housing in both directions so bearing rollers seat properly. Gradually increase ram pressure with case still rotating and "feel" for preload on bearings.

3) As soon as slight preload is felt, install a bolt in differential bearing support pedestal which is nearest to pinion gear, then, using a pound pull scale hooked to pedestal bolt, rotate case by pulling on scale. Keep scale at right angles to a line through center of pedestal bolt and through center of pinion gear. Note reading on scale while carrier is steadily rotated (disregard pull required to start carrier rotating). *NOTE - The distance from center of pedestal bolt to center of pinion gear is approximately 2½". The scale reading in pounds, multiplied by 2½" (radius) is the actual pinion bearing preload.* Specified pinion bearing preload is 5 to 15 inch-pounds with 5000 lbs. pressure applied (minimum scale reading should be 2 lbs., and maximum scale reading should be 6 lbs.). To **increase** preload, decrease the preload shim pack thickness. To **decrease** preload, increase shim pack thickness.

4) Adjust shim pack thickness as required, then press a new pinion flange seal into carrier housing with Tool T53T-4676-B. Support pinion gear on press bed and press pinion shaft flange into position with Tool T53T-4851-B. Remove carrier assembly from press and mount it in an overhaul stand, then install flat washer and nut on pinion shaft. Hold pinion flange and tighten shaft nut to 200-275 ft. lbs.

ALL MODELS

Differential Assembly: If the drive gear runout check during disassembly exceeded .008", the condition may be caused by a warped gear, defective case, or by excessively worn differential bearings. To determine cause of excessive runout, before riveting gear to case, press the differential side bearings in place on case hubs until seated against shoulders of case. Assemble the two halves of case, aligning marks made at disassembly. Tighten differential case capscrews or nuts to 23-31 ft. lbs. (350 Series); 50-70 ft. lbs. (500 Series); 80-105 ft. lbs. (600 Series). Install case in differential carrier, then check runout of case flange with a dial indicator. If runout exceeds .005", the drive gear is true and the condition is due to either a defective case or differential side bearings. Install new bearings on case hubs, and install case in carrier, then check runout again. If runout is still excessive, the differential case is defective and must be replaced. After the condition has been corrected, disassemble differential case. Position drive gear on case flange, then attach drive gear to case with rivets. *(CAUTION - Be sure drive gear and case are clean, and the drive gear is not cocked before riveting gear to case. Cold rivets must be used to attach gear to case).* Apply a thin coating of lubricant on spider, side gears and thrust washer, then assemble them in drive gear half of case. Install cap screws or bolts and nuts, and tighten to correct torque. Install lock wire.

FORD TRUCK "BANJO HOUSING" HYPOID AXLE

Drive Gear Adjustment: Place side gear bearing cups over side bearings, and position differential assembly in carrier. Position bearing adjusters in carrier, making sure the adjuster threads mesh with threads in carrier. Install bearing caps in their original position using the aligning marks made at disassembly, as a guide. Install bearing cap bolts and tighten to 81-106 ft. lbs. (350 Series); 80-100 ft lbs. (500 Series); 110-145 ft. lbs. (600 Series). *(NOTE - Th bearing adjust rs and bearing cups can b m ved with the bearing cap bolts at n rmal t rqu).* Tighten bearing adjusters hand tight against side bearing cups. Turn left hand adjuster until drive gear is loosely meshed with pinion gear. Mount a dial indicator on carrier flange with the contact button bearing against back of gear or differential carrier, then loosen the right hand adjusting nut just enough to notice endplay on indicator. Tighten this adjuster until zero endplay is obtained. Tighten each adjuster one notch from the zero endplay position to pre-load differential bearings. Mount the dial indicator on the carrier so contact button bears against rear face of ring gear tooth, then adjust drive gear to obtain .006-.012" backlash. To reduce backlash, loosen right hand adjuster and tighten left hand adjuster equally. To increase backlash, perform the same operation in reverse. Check gear tooth contact for correct pattern. If tooth contact adjustment is necessary, the drive pinion position may be changed by varying the thickness of shim pack between pinion case and carrier. Adjust drive gear position by bearing adjusters.

Differential Carrier Installati n: Place a new carrier to housing gasket on axle housing making sure the puller bolt holes in gasket are aligned with holes in housing. Place differential carrier assembly on a roller jack, then roll carrier into position. Start carrier into housing with four cap screws equally spaced. Tighten cap screws alternately to draw carrier squarely into housing. Install remaining carrier to housing screws, lockwashers and tighten to 53-59 ft. lbs.

INSTALLATION OF REAR AXLE ASSEMBLY: *Se "Rear Axl " on Truck M d l pag .*

FORD TRUCK HYPOID

F-250 & P-350 Trucks (1956-60)

DESCRIPTION: Spicer Model 60. Full-floating, hypoid gear with Hotchkiss drive. **This axle does not have a s parat diff rential carri r assembly.**

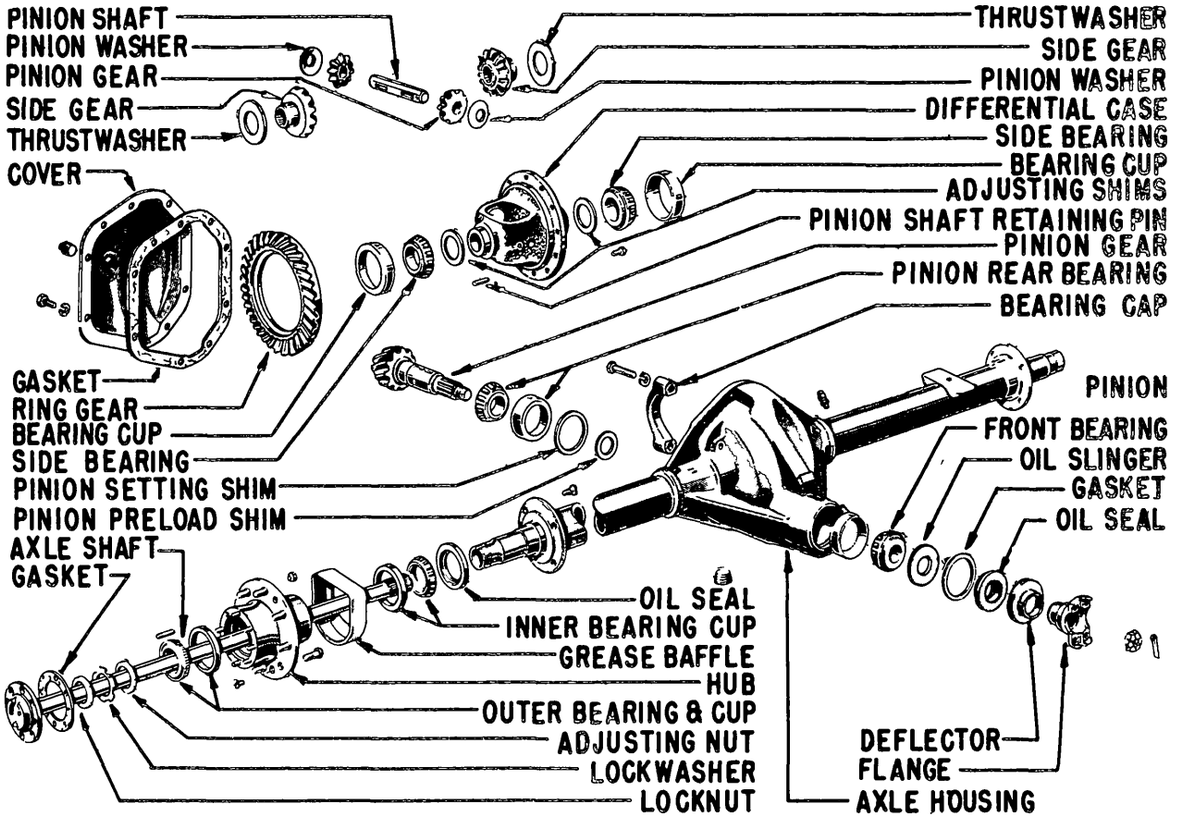
REMOVAL OF REAR AXLE ASSEMBLY: *See "Rear Axl " on Truck Mod l pag s.*

AXLE SHAFT REPLACEMENT: Remove axle shaft stud nuts and lockwashers. Strike center of axle shaft flange with a hammer and drift to loosen tapered dowels, then remove dowels. Pull axle shaft from housing. To reinstall, place gasket in position on housing and install axle shaft. Install tapered dowels, lockwashers and nuts on studs. Tighten nuts to 50-70 ft. lbs.

WHEEL BEARING ADJUSTMENT: Remove axle shaft (see above), bearing locknut and washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt, then back off adjusting nut 1/8 turn. Install bearing lockwasher and locknut and bend one tab of lockwasher over adjusting nut and one tab over locknut. Install axle shaft.

OVERHAUL: With axle housing removed from truck, remove axle shafts (see above), then proceed as follows:

Disass mbly: 1) Remove rear cover from rear axle housing. Rotate gears to check for roughness and inspect teeth for scoring, flaking, or abnormal wear. Check backlash and runout of ring gear (see below).



2) Mark side bearing caps and housing to assure reassembly of caps in same position, then remove caps. Install housing spreader Tool 4000-A, and spread housing until differential assembly can be forced out with a pry bar or heavy screwdriver. *CAUTION - Do not spread housing m r than .020" t remove differential assembly. Loos n th spr ad r imm diately after lifting out differ ntial ass mbly to pr vent springing the housing.*

3) Using Tool T56L-400-A, remove differential side bearings. Remove and tag shim packs which were installed under each bearing. Remove drive gears from differential case. Drive out pinion shaft lock pin with a punch and remove differential pinion shaft, differential pinions, and thrust washers. Remove side gears and thrust washers.

4) Hold universal joint flange with Tool T53L-4851-D & E and remove nut and washer from pinion shaft. Remove universal joint flange with Tool T53L-4851-A. Press pinion shaft out of housing. If rear bearing cone is to be replaced, use Tool T56T-4630-A (4.88-1 ratio axle), 4630-B (5.87-1 ratio axle), 4630-C (4.55-1 ratio axle), and press cone off pinion shaft. Remove oil seal with Tool 4676-N.

5) Remove oil slinger, pinion front bearing cone, and pinion bearing preload adjusting shim pack (located between front bearing cone and shoulder on pinion shaft). If pinion bearing cups are to be replaced, use Tool T55P-4616-B (front cup), T53T-4616-E (rear cup). Measure thickness of shims found back of rear bearing cup and record the reading or tie shims together for reinstallation.

Inspection: Wash all parts with solvent and blow dry with air then oil all bearings. Check gear teeth for scoring or signs of wear. Check differential side gear hubs, thrust washers, splines and thrust surfaces for pitting or wear. Check bearing cups for rings, galling, scores, and for erratic wear pattern. Make sure that all bearing cups are seated properly in their bores. Temporarily install bearing caps and test fit of adjusting nuts in their threads. They should turn easily when bearing caps are tightened to specifications. Face of nuts must be smooth and square. Polish with a fine abrasive on a flat surface. Remove all nicks and burrs from mating and mounting surfaces.

FORD F-250 & P-350 TRUCK REAR AXLE

Differential Case Reassembly: Install side gears and thrust washers, pinion gears and thrust washers, and pinion shaft in differential case. Install pinion shaft locking pin. Install drive gear on differential case and tighten attaching bolts to 70-90 ft. lbs. Install both differential side bearings on case without shims. Make sure that bearings bottom on shoulders of case. Place cups on bearings and install complete assembly in rear axle housing. Install bearing caps and tighten cap bolts just enough to keep bearing caps in place. Mount a dial indicator on axle housing with indicator button against back side of ring gear. Pry differential assembly away from dial indicator with a screwdriver, then set dial indicator to zero. Pry differential assembly toward dial indicator and note indicator reading. Record this reading for reference when installing differential case in axle housing as it represents the total amount of shims (less those required for bearing preload) necessary to take up clearance between differential cups and case. Remove differential case assembly from axle housing. *NOTE - Do not install shims under bearings at this tim .*

Pinion Gear Assembly Installation: With correct pinion depth adjustment shim pack and pinion bearing preload adjustment shim pack selected (see below), install front and rear bearing cups in axle housing (shim pack back of rear bearing cup), using Tool T56T-4616-A and T53T-1239-A. Press rear bearing on pinion shaft with Tool T53T-4621-B and install pinion assembly in housing. Install correct pinion bearing preload adjusting shims on pinion against shoulder and install front bearing. Install oil slinger, oil seal (soak new seal in oil for 30 minutes before installation). Install universal joint flange, washer, and nut. Tighten nut to 200-250 ft. lbs.

Pini n D pth Setting (Shim Sel ction M th d) - *(NOTE - This m thod can b us d when nly a n w ring g ar and pini n ar installed. Should any f th carrier housing*

CONTINUED ON NEXT PAGE

FORD TRUCK HYPOID (C nt.)

parts be changed, or if tooth contact patt rn not correct, the "Master Gauge Method", below, must be used). The thickness of shims required is determined by thickness of shim pack removed at disassembly and by the plus or minus figure etched on pinion. For example, if original pinion was marked +2 and had a .035" shim pack back of rear bearing cup, and the new pinion to be installed is marked −1, the shim pack must be increased by .003" to bring new pinion to its correct position. *NOTE* - A (+) marked pinion calls for the removal of shims in the amount of the marking. A (−) marked pinion calls for addition of shims in the amount of the marking. Replacement shims are available in .003"& .005" thicknesses.

Pinion Depth Setting (Using Gauge T56T-4020-A) - *(NOTE - This method must be used whenever any of the carrier housing parts are changed or when the original shim pack thickness is unknown).* Install pinion in housing (see above) without the front bearing preload adjusting shim pack. Install universal joint flange, flat washer and nut, then tighten nut until pinion bearing preload is 10-30 inch pounds (see "Pinion Bearing Preload" below for checking procedure); as pinion shaft nut is tightened, rotate pinion shaft to seat bearing rollers. Place gauge shaft and discs in differential bearing pockets and tighten caps on larger discs only. Attach dial indicator to its holder and place it on highest step of gauge block. Place gauge block squarely on pinion gear and squarely against gauge shaft. With indicator button resting on gauge block, set dial indicator to zero. Swing indicator to highest point on gauge block and note reading *(NOTE - The highest point on gauge shaft is highest indicator reading while indicator hand is moving clockwise).* The indicator reading at this point must correspond to marking on pinion gear. A (+) reading (clockwise from zero) at highest point on gauge shaft with a zero marked pinion means that the actual dimension is too great in the amount of the plus reading. To correct, add shims that correspond to the plus reading. For a (−) reading (counterclockwise from zero) at the highest point on gauge shaft with a zero marked pinion, remove shims equal to the minus reading. *NOTE* - A −3 marked pinion is installed at the proper depth when the indicator reads −3 at the highest point on gauge shaft. Similarly, a +3 marked pinion is installed at the correct depth when the indicator reads +3.

Pinion Bearing Preload Adjustment - *(NOTE - When pinion setting shim pack is changed (see above), add or subtract the same thickness of shims from pinion bearing preload shim pack at front bearing to maintain correct pinion bearing preload).* To check preload, wrap a strong cord around universal joint flange and attach a pound-pull scale to cord. Note the pull required to keep pinion shaft rotating (disregard pull required to start pinion rotating), which should be **10-30 inch pounds.** *NOTE* - The inch-pound torque required to keep pinion shaft rotating is calculated by multiplying the scale reading in pounds, with one half the diameter in inches. As an example, a 15 lb. pull on a 4" diameter is 30 inch pounds.

Differential Case Installation: With pinion shaft correctly installed in housing (pinion setting & bearing preload adjusted), install differential assembly (with correct shim packs back of bearing cones; see "Differential Bearing Preload & Backlash Adjustment" below), as follows: Install housing spreader Tool 4000-A and spread housing not more than .020". Install differential assembly, with bearing cups in position on bearings, into rear axle housing. Rotate and tap ring gear with a soft hammer to seat bearings properly in cross-bores. Install bearing caps (make sure indexing marks made at disassembly are in alingment), then remove housing spreader. Install and tighten capscrews to 70-90 ft. lbs. Check backlash (see below). Install rear cover and gasket and tighten capscrews to 15-25 ft. lbs.

Differential Bearing Prel ad & Backlash Adjustment - With differential bearings installed on case without shim packs, install case, with bearing cups, in housing. Install bearing caps and tighten bolts lightly. Mount a dial indicator on housing with indicator button bearing against back side of ring gear. Move differential assembly tight against pinion gear and set dial indicator at zero. Move differential assembly toward indicator and note maximum reading *(NOTE* - This reading indicates the shim pack thickness required behind bearing cone on ring gear side of case). To obtain shim pack required for opposite side of case, take the reading just obtained and subtract it from the reading taken when differential case was reassembled and checked in rear axle housing (see "Differential Case Reassembly) above). The remainder, plus .015-.020" for preload and backlash, will be total shim pack required on side of case opposite the ring gear. As an example, if the reading obtained when differential case clearance checked in axle housing was .070" and the reading obtained on dial indicator (above) was .038", then the thickness of shims required on opposite side of housing from ring gear, would be .070" minus .038"; or .032" to which should be added .015-.020" (.017") shims for preload and backlash, giving a total shim pack of .049". Remove bearing caps and take differential case out of housing. Remove side bearings and install proper amount of shims on each side. Press side bearings on case until they are firmly seated against shims. Install differential case in housing.

Differential Ring Gear Backlash Ch ck: Install a dial indicator to check backlash at four equally spaced points around ring gear. The backlash must be .004-.009" and must not vary more than .002" between positions checked. If backlash does not meet specifications, change the shim packs behind both differential side gears by taking shims from one side and installing them on the other as required. Total shim pack must not be changed.

FORD TRUCK TWO-SPEED

F, B, C-500 & 600, P-500 Series (1954-60)

DESCRIPTION: Two-speed planetary differential assembly with either a spiral bevel or hypoid ring gear and pinion. Spiral bevel pinion shaft is piloted at rear by a roller bearing. Shift control is electrically operated.

►*AXLE IDENTIFICATION NOTE: Eaton model numbers ar cast in housing n right side of cover.*

CONTROL UNIT: *See "C ntrol Unit" be low.*

REMOVAL OF AXLE: *See "Rear Axle" on Truck Model pag s.*

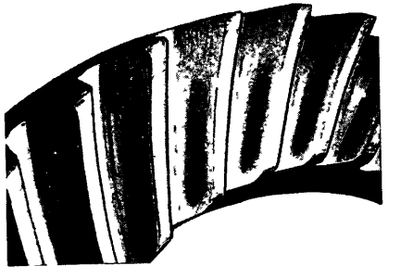
AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Same as for full-floating truck axle. *Se "R ar Axl " on Truck Model pages.*

REAR AXLE RATIO: *See "Rear Axle" on Truck Model pag s.*

OVERHAUL: Carrier Assembly Removal - Shift axle into low ratio, then drain lubricant from housing. Remove axle shaft stud nuts. Hold a short drift firmly in center of axle shaft flange and strike it sharply to loosen tapered dowels in flange, then remove dowels and axle shaft. Remove electric shift unit from carrier housing and disconnect drive shaft at rear universal joint. Support carrier on a roller jack and remove carrier attaching bolts. Remove carrier and discard axle housing gasket.

Disass mbly: Remove oil distributor plug and gasket and pull oil distributor and spring out of carrier. Remove shift fork shaft plugs and remove shaft, then remove shift fork and seal from housing. Pull sliding clutch gear out of carrier, then mark right and left hand bearing adjusters with a punch for reference at reassembly. Remove bearing cap bolts, caps, adjusters, and locks. Lift differential and planetary assembly out of carrier and remove side bearing cups. Remove lock wire and nuts from bolts holding drive gear to gear support cases and remove bolts. Tap drive gear with a brass hammer and remove right hand gear support case, then remove left hand gear support case, high speed clutch plate thrust washer, and oil collector drum. Slide drive gear off differential and planetary gear assembly and remove high speed clutch plate by tapping on each side alternately with a soft hammer. Remove planetary gears and gear pin, then remove lock wire and capscrews from differential assembly and separate right and left hand differential cases. Remove differential side gears and thrust washers, differential spider gears, thrust washers, and differential spider. After removing flange nut, drive flange off drive pinion with a soft hammer. Remove bolts retaining pinion bearing sleeve to carrier housing, then use a drift and drive pinion assembly out front of case. Place pinion assembly on a press bed and press pinion shaft out of flange and front bearing cone, then remove bearing preload spacer from pinion shaft. If pinion rear bearing cone is to be replaced, remove pilot bearing (if so equipped) with Tool CJ-951, or equivalent, and an arbor press. Remove rear pinion bearing with a suitable tool or use a blunt chisel and tap on bearing cone between teeth of pinion. Remove bearings from gear support cases by using a drift and striking bearing inner race through holes provided in support case. *NOTE - To install a n w bearing on support case, install cas in an arbor pr ss, th n plac a short square ste l bar across inn r bearing rac and press b aring on until it is flush with should r of cas . R peat for oth r half of case.* Place drive pinion sleeve in a press, then insert a steel bar through hole in sleeve between bearing cups and press out one of the cups. Turn sleeve over and remove other bearing cup in same manner.

Pinion Bearing Preload Adjustment: Completely assemble pinion and bearing retainer (without oil seal) and tighten pinion shaft nut to 200-325 ft. lbs. (Eaton Axle Model 1350); 325-450 ft. lbs. (Eaton Axle Models 13602 & 13800). Check preload as follows: Clamp the universal joint flange of pinion shaft assembly in a vise, then wrap a strong cord around pinion bearing retainer. Attach a pound-pull scale to end of cord, then note the pull required to keep pinion bearing retainer rotating (disregarding pull required to start retainer moving). The reading on scale multiplied by one-half the diameter of bearing retainer (in inches) at point the cord is wrapped, is the inch-pound torque. Bearing preload torque should be 15-30 inch pounds. To adjust preload, install pinion bearing spacer of proper length. *NOTE - A shorter spacer increases preload and a longer spacer decreases preload. Original spacers are not marked and must be measured with a micrometer to determine length.*



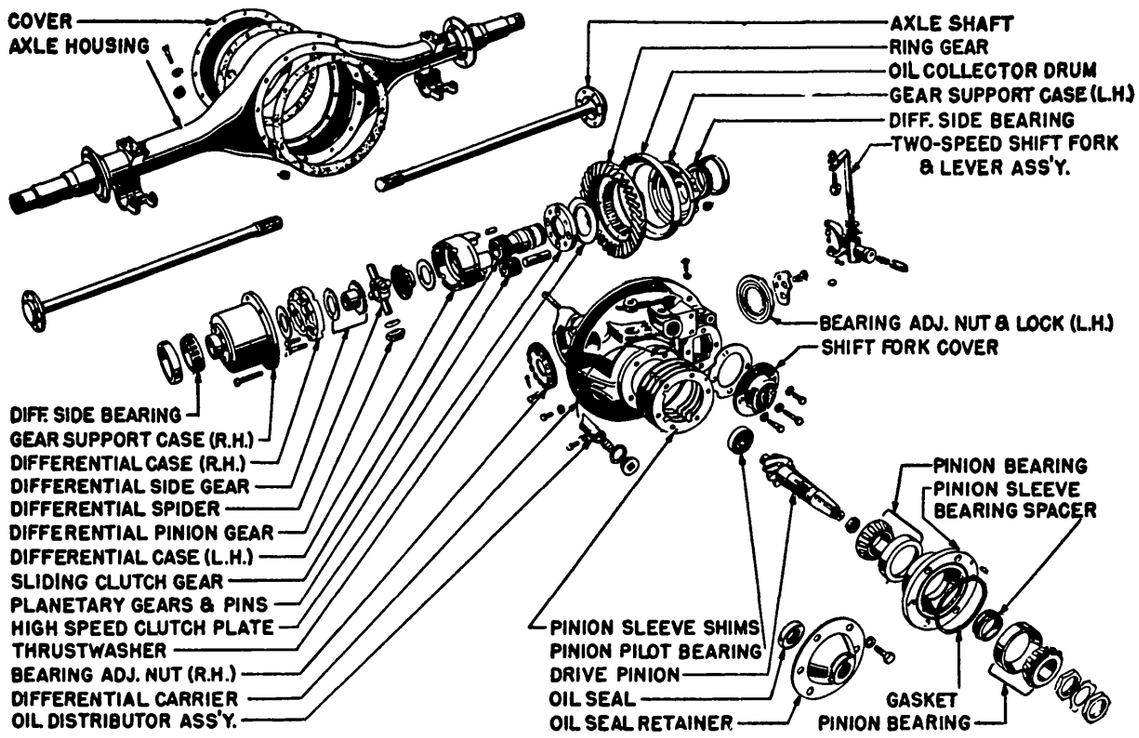
Pinion Depth Adjustment: *NOTE - Pinion depth is adjusted by adding or removing shims between pinion bearing sleeve and carrier housing.* If the old ring gear and pinion are being installed, install the same shim pack that was removed at disassembly. If a new ring gear and pinion are being installed, adjust shim pack thickness in accordance with "plus" or "minus" marking on new pinion assembly. As an example: Original shim pack is .015", original pinion is marked −1, and new pinion is marked +1. The new pinion should require a .002" thicker shim pack (total .017"). If new pinion is marked same as old pinion, no shim change is required. *NOTE - After axle is completely assembled and adjusted, check tooth contact pattern (see below).*

Ring Gear & Pinion Tooth Contact Pattern Check: With carrier completely reassembled, pinion depth and ring gear backlash properly adjusted, check gear tooth pattern as follows: Paint gear teeth with a suitable gear marking compound, such as a paste made with dry red lead and oil, then wrap a cloth around drive pinion flange to act as a brake. Rotate drive gear back and forth (use a box wrench on ring gear attaching bolts for a lever) until a clear tooth contact pattern is obtained, then compare pattern with illustration of correct tooth pattern. *NOTE - Some minor differences will exist on individual gear sets but, in general, desirable patterns will have the following characteristics: (1) Drive pattern should be centered on tooth. (2) Coast pattern should be centered on tooth but may be slightly toward toe. (3) There should be some clearance between pattern and top of tooth.* Adjust pinion setting shim pack and/or backlash to obtain correct pattern.

Differential Bearing Preload & Backlash Adjustment: Mesh drive gear and pinion with a slight amount of backlash, then set adjusting nuts in carrier bearing pocket threads, so they just contact bearing cups. Position bearing caps on carrier, matching the marks made when carrier was disassembled. Install bearing

CORRECT TOOTH PATTERN (EXC. PILOTED PINION SHAFT)

CORRECT TOOTH PATTERN (PILOTED PINION SHAFT)



cap bolts or stud nuts and alternately tighten to 150-175 ft. lbs. *CAUTION - Check adjusting nuts for freedom of movement as bolts are tightened. If adjusting nuts do not turn freely, remove bearing caps and insp ct for damaged threads or incorrectly positioned caps.* Alternately tighten adjusting nuts until there is some backlash between drive gear and pinion and there is some preload on bearings. While bearings are preloaded, rotate drive gear several turns in each direction to seat bearing rollers in cups. Loosen bearing adjusting nuts until they are clear of bearing cups, then tighten them until they just touch bearing cups. Install a dial indicator on carrier housing with button against back face of drive gear, then adjust differential endplay at zero without preloading differential bearings. From zero endplay and zero preload condition, tighten each bearing adjusting nut 1½-2 notches to preload the bearings. Mount dial indicator to check drive gear backlash and check backlash at four equally spaced points on drive gear. Backlash should be adjusted to the best contact pattern within the range of .006-.016". To reduce backlash, loosen drive gear side adjusting nut and tighten pinion side adjusting nut the same number of notches. To increase backlash, perform same operation in reverse. *NOTE - When moving adjusting nuts, th final movement should always be made in a tightening direction. As an example: If one nut is to be loosen d ne n tch, loosen it two notch s, th n tight n it n .*

Reassembly: Press new pilot bearing on pinion shaft (if so equipped) and stake pinion shaft end at six points,

CONTINUED ON NEXT PAGE

FORD TRUCK TWO-SPEED (C nt.)

then press pinion rear bearing on pinion shaft until seated. To install a new bearing cup, place pinion sleeve in a press and, using a steel bar, press cup into sleeve until it is seated against recess in sleeve. Repeat this operation for other cup. Install pinion in bearing retainer and place old spacer on shaft for a trial build-up, then install pinion front bearing. Check and adjust pinion bearing preload (see above). Install a new oil seal in seal retainer or bearing retainer, then install universal joint flange flat washer and pinion shaft nut. Tighten nut to 200-325 ft. lbs. (Eaton Axle Model 1350); 325-450 ft. lbs. (Eaton Axle Model 13600 & 13602). *NOTE - If a new pinion and ring gear are being installed, adjust shim pack between pinion bearing retainer and carrier housing. See "Pinion Depth Adjustment" above.* Install a new gasket in pinion bearing retainer (if so equipped), then place shim pack on bearing retainer and install pinion and retainer assembly in carrier housing. Install bolts and lockwashers and tighten to 100-125 ft. lbs. Place left hand half of differential case in a vise with planetary side facing downward, then place one differential side gear thrust washer in place in case with chamfered side facing upward. Place differential left hand side gear (with short hub) in position in case. Install four differential pinions and thrust washers on differential spider, then place spider in differential case. Place differential right hand side gear and thrust washer (chamfered side of washer facing downward) on pinions, then place right hand side of the case in position over differential spider. Install and tighten differential case bolts to 50-70 ft. lbs. Place differential assembly on bench and insert the four planetary gear pins in holes in differential case. Place four planetary gears in position on pins, then position high speed clutch plate on planetary gear pins with chamfered teeth facing planetary gears. Tap plate into place with a soft hammer. Place right hand gear support case in a vise with bearing side facing downward and position gear support thrust washer in case. Place differential assembly in gear support case with with planetary end facing upward, then place drive gear over differential assembly with teeth on drive gear facing downward and mesh planetary gears with internal teeth on drive gear. Line up bolt holes in drive gear with bolt holes in gear support case. Place oil collector drum on drive gear with open side facing gear (place notches in oil collector drum between bolt holes in drive gear). Apply oil to each side of high speed clutch plate thrust washer, then position washer on high speed clutch plate. Place left hand gear support case on drive gear and line up bolt holes in drive gear and both gear support cases. Install bolts through gear support cases with bolt heads against flange of right hand gear support case. Install nuts and tighten to 50-70 ft. lbs., then install lock wire. Install differential assembly in carrier housing and adjust backlash and preload (see above). Check and adjust gear tooth pattern (see above). Install sliding clutch gear, then position shift fork on sliding clutch gear. Install shift fork shaft through hole in differential carrier and into shift fork, then install shift fork shaft plugs. Place shift fork seal and retainer on shift fork and shift axle into low range. Place oil distributor and spring in position in carrier and install distributor plug and gasket.

FORD TRUCK TWO-SPEED REAR AXLE (SPIRAL BEVEL)

Installation: Install guide studs in axle housing, then place new gasket over guide studs. Install carrier in axle housing, then install and tighten bolts to 50-70 ft. lbs.

TWO-SPEED CONTROL UNIT

ELECTRIC CONTROL UNIT OPERATION: High Speed Range—With control button on gear shift lever in upper position, current is supplied to the motor in the rear axle shift unit, causing motor to rotate in a clockwise direction and move drive screw assembly nut toward bottom of screw. When nut has traveled far enough to wind the torsion spring, a contact bumper on the nut breaks electrical connection on automatic switch and stops the motor. The nut is held at the end of its travel by a ball screw detent spring mounted on front cover. As nut is moved downward, a spring winding lever, which pivots on a pin in the nut, winds the torsion spring. The axle is ready to shift into high range as soon as the load on the rear axle gears is relieved. The torsion spring is assembled in the unit under 50 to 80 lbs. pressure. When spring is wound, the tension is increased to 90 to 150 lbs. This additional pressure is used to shift the axle. When shift is completed, the ends of the spring come together, leaving the original tension in the spring. This preload tension holds the axle in either range.

Low Speed Range—When button is placed in the down position, current is supplied to opposite field of motor and to speedometer adapter (adapter is mounted on speedometer and compensates for variation in speed of drive shaft between high and low ranges of the axle). Motor rotates in opposite direction (counter-clockwise) to that of high range operation, causing the drive screw assembly nut to travel toward top of screw. Torsion spring is wound for a shift to low range which is accomplished in the same manner as for high range.

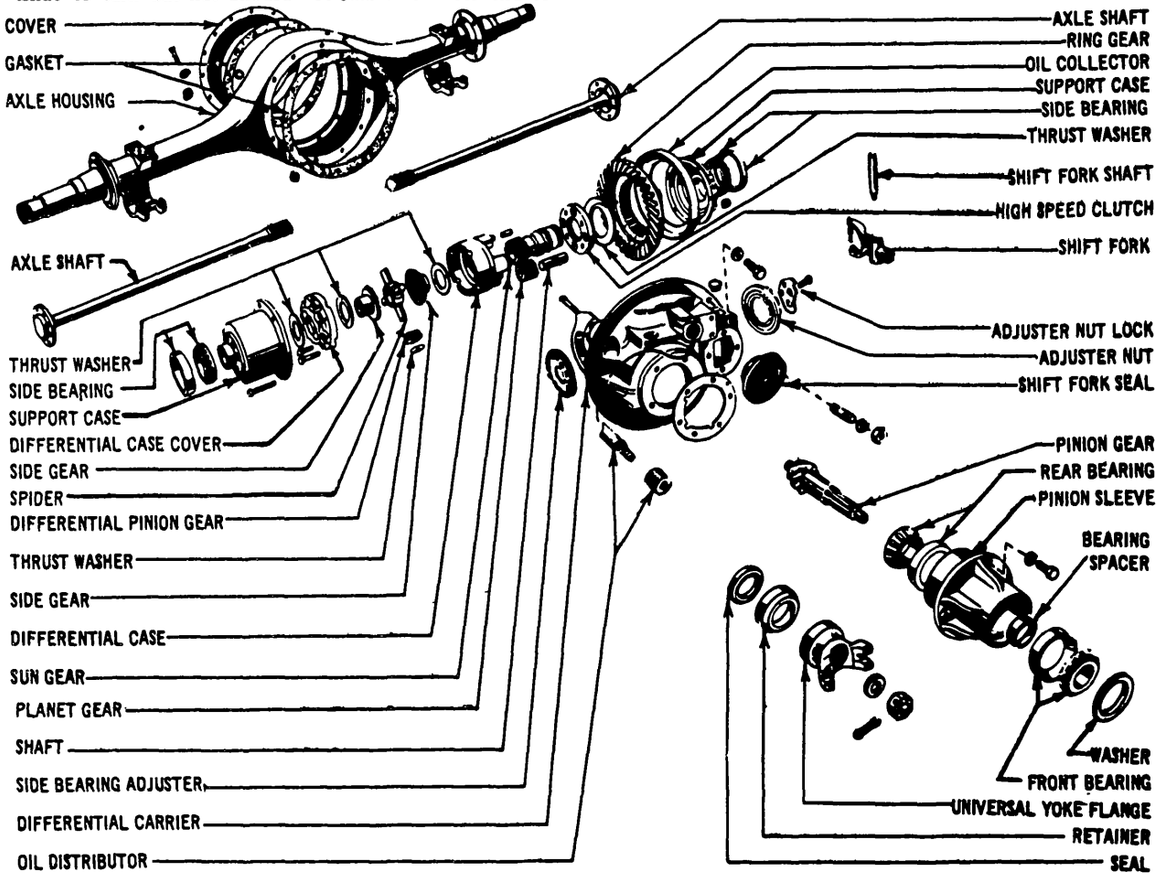
Electric Control Unit Lubricati n—Change oil in unit every 10,000 miles using SAE 10W engine oil.

ELECTRIC CONTROL UNIT OVERHAUL: *(NOTE—Speedometer adapter, circuit break r, and contr l switch cannot be repair d and must b replac d if failure occurs).*

Removal: Disconnect one of the battery cables. Remove two shift housing to carrier stud nuts and lockwashers and remove unit from carrier.

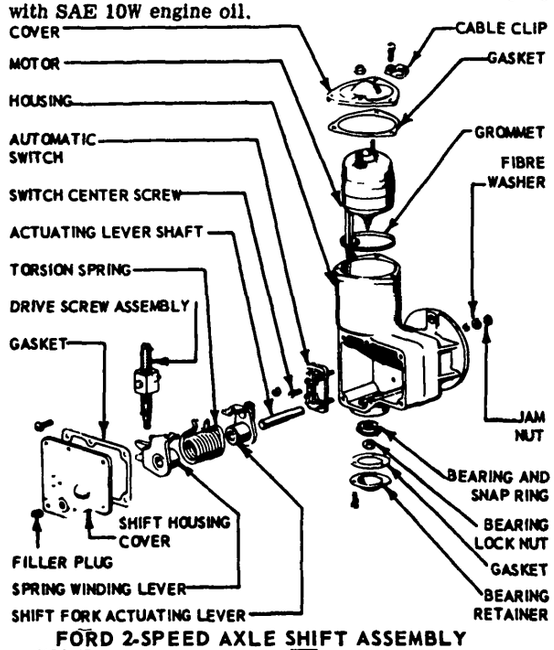
Disassembly: Remove front cover and drain the lubricant. Turn drive screw until nut is in the center of the screw *(CAUTION—This is important t av id damag to driv nut c ntact bump r).* Pull shaft out of tension spring assembly and remove assembly from housing. Remove screws and lockwashers which attach drive screw bearing cover to housing, then remove cover and gasket.

CONTINUED ON NEXT PAGE



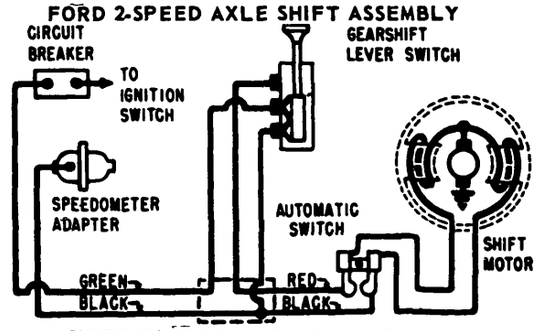
FORD TRUCK TWO-SPEED CONTROL UNIT (C nt.)

Push down on screw assembly until the bearing is forced out of housing. Remove bearing retainer nut and bearing (hold shaft with a screwdriver inserted in drive slot). Remove locknuts from automatic switch terminals and remove motor wires from terminals. Remove motor cover screws and remove motor, cover, and gasket from housing. Remove jam nuts and fibre washers from terminals at rear of housing. Remove automatic switch center screw and lift switch out of housing. Mount torsion spring and lever assembly in a vise. Turnspring winding lever clockwise, and pull outward to disengage spring from lever.



Insp cti n: Wash all parts except motor in cleaning solvent. Check all parts for signs of failure. Check automatic switch points for cleanliness and free movement. Make sure that points will close firmly under spring tension. Chęck operation of drive screw by rotating screw while holding nut. The screw must turn freely. When nut reaches end of screw, the screw should continue to turn but nut should not jam or run off end of screw. Turn screw in opposite direction and check operation at top end of screw. The fibre bumper in nut should be a tight press fit. Check stall torque of shift motor as follows: Place a wrench on rectangular drive of motor shaft. Hold wrench in one hand, hold motor itself in vise. Connect one motor wire to battery terminal and connect motor housing to other terminal. The wrench should tend to turn with a pull of about six inch pounds. Allow the wrench to turn very slowly, making sure that this torque is present for the full 360° turn of the wrench. *(NOTE–While testing the motor, do not allow it to overheat).* Check rubber diaphragm and make sure that spring clamp is in position in diaphragm groove and that it clamps diaphragm tightly around shift fork. Replace diaphragm if it is not in good condition or if it is not tight on shift fork.

Reassembly: Position rubber diaphragm on shift shaft (refer to lettering on face of diaphragm for correct position). If torsion spring assembly was disassembled, locate parts in the correct position and turn spring clockwise until end of spring is past the shift fork operating lever, then push lever inward until spring is locked in place. Position automatic switch in housing, then install switch attaching screw. Install fibre washers and jam nuts on the switch terminals at rear of housing. Place motor cover gasket on housing, then install motor and cover on housing. Install cover screws. Position motor wires on automatic switch terminals and install locknuts. Place drive screw assembly in housing and install drive screw bearing and bearing retainer nut. Tap bearing into seat in housing and install cover and gasket. Center drive screw nut on drive screw, making sure the contact bumper on nut is toward automatic switch. Position torsion spring assembly in housing and install shaft. Install housing cover and gasket and tighten attaching screws securely. Install lead wires on housing terminals with the **red wire on the bott m terminal.**



Installation: Position shift unit on carrier studs with the torsion spring swivel block installed in shift fork slot, then install nuts and lockwashers. Tighten nuts to 50-70 ft. lbs. Fill shift unit to level of filler plug with SAE 10W engine oil.

FORD TRUCK TWO-SPEED REAR AXLE (HYPOID)

FORD 2-SPEED AXLE SHIFT ASSEMBLY

SHIFT CONTROL WIRING DIAGRAM

LINCOLN & CONTINENTAL HYPOID

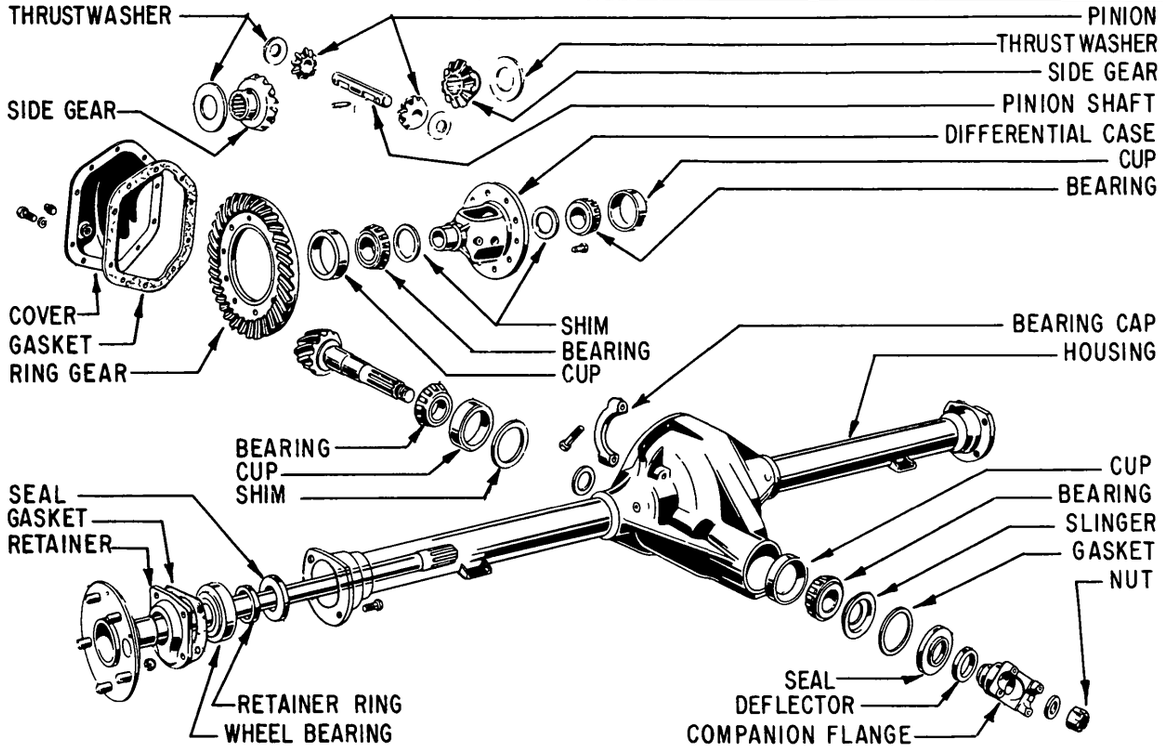
Linc ln & C ntin ntal (1959-60)

►*PINION DEPTH GAUGE, TOOL NO. 4020-B, INSTALLATION CHANGE (To insure hold-down clamp centering on pinion):* Because of increased pinion offset, it will be necessary to remove hold-down screw from clamp bar and insert it from the opposite side, then, install clamp bar in an inverted position on rear axle housing. This will cause hold-down screw and anvil to seat securely on end of pinion gear.

DESCRIPTION: Semi-floating hypoid gear type with Hotchkiss drive. Differential carrier assembly is integral with rear axle housing.

REMOVAL: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REPLACEMENT: Removal – Remove wheel, then remove nuts securing brake drum to axle flange and remove drum. Work through hole provided in axle shaft flange and remove nuts securing wheel bearing retainer. Pull axle shaft out of housing with Tool 4235-C2, being careful not to damage the oil seal or dislodge brake backing plate. After axle is removed, install one nut to hold backing plate in position.



Installation: Apply lubricant to seal and bearing bore and install a new brake plate gasket. Install axle shaft into housing and differential side gear, being careful not to damage oil seal. *CAUTION – Right and left hand axle shafts are not the same length. Longer shaft should be installed in right hand side.* Install retainer plate and tighten nuts to 50–65 ft. lbs., then install brake drum and secure with Tinnerman nuts. Install wheel assembly.

AXLE SHAFT SEAL & BEARING REPLACEMENT: Removal – With axle shaft removed, remove seal with Tool 1175–AE. To remove wheel bearing, cut bearing retainer off with a chisel, being very careful not to damage axle shaft. Install Tool 1225–D on bearing, then install axle shaft and bearing assembly in an arbor press and remove bearing.

Installation: Place retainer plate on axle shaft and press new bearing on shaft with Tool 1225–D and an arbor press, then press on a new retainer ring. *CAUTION – Do not attempt to press both wheel bearing and retainer n at the same time.* Coat outside edges of new seal with sealing compound, then drive seal tight against shoulder with Tool 4245–B and a light soft faced hammer. Replace axle shaft and wheel.

DRIVE PINION SEAL & COMPANION FLANGE REPLACEMENT: Removal – *CAUTION – Mark universal joint, drive shaft and companion flange so that all parts will be installed in the original position. In the vent drive shaft, companion flange or universal joint are replaced, it will be necessary to reposition replacement parts until correct driveline balance is obtained.* Disconnect rear universal, then remove nut from pinion shaft with Tool 4851–G or J. Remove companion flange with Tool 4858–D (remove dust shield if damaged). Remove pinion shaft seal assembly with Tool 1175–AE.

Installation: Start a new seal over drive pinion with sealing edge facing inward. *NOTE – Soak neoprene seal in engine oil for 20 minutes before installing.* Coat lip of seal with lubricant, Part No. B9L–19A508, and drive seal into position with Tool 4676. Start a new dust shield (deflector) over companion flange and drive it into position with Tool 4859. Coat inside of companion flange with same lubricant used on seal lip and start it over drive pinion, aligning the reference marks made at time of removal. Use Tool 4858–B to press flange into position and tighten nut to 180–200 ft. lbs. Attach rear universal joint to companion flange, aligning the reference marks.

LINCOLN REAR AXLE

OVERHAUL

DIFFERENTIAL CASE: Place rear axle housing in a suitable holding fixture, then clean exterior of housing thoroughly. Remove housing cover and clean all internal parts with solvent. Before removing differential case, check the following:

Ring Gear Runout – Attach dial indicator, Tool 4201–A to differential housing so actuating plunger of indicator bears against rear face of ring gear. With indicator at zero setting, revolve ring gear one revolution and note total runout which must not exceed .006".

Side Bearing Clearance – Check clearance between side bearing caps and bearing cups. If clearance is .003" or more, it could indicate that bearing is turning in housing. Check to make sure cap is properly seated against mating surface of housing.

Ring Gear & Pinion Gear Tooth Contact – Inspect tooth contact using a suitable gear marking compound.

Removal: Remove differential side bearing caps. *NOTE – Identification marks are stamped on differential housing and on each bearing cap.* Install housing spreader, Tool 4000–A, making certain that dowels on tool registers with openings in housing, then tighten hold-down bolts. Spread the housing opening approximately .015", then pry carrier assembly loose and remove from housing. *Id ntify b arings and cups so they may be r install d in th ir original position.*

Disass mbly: Position differential case in a suitable fixture (Tool 4205–B), then install Tool 4221–C so fingers of tool are located in cast recesses of case and pull one differential side bearing. *NOTE – If ring gear and pinion are to be reassembled, note the number and thickness of shims found between side bearing and case.* Remove second bearing in the same manner. Remove ring gear from case, then drive out pin locking pinion shaft to case and remove shaft, differential pinions, side gears and thrust washers. With pinion shaft in a vertical position, remove nut from pinion shaft with Tool 4851–G or J, then check pinion bearing preload *(see "Pinion Bearing Preload" below).* Remove companion flange and pinion shaft seal (see above). Lift out gasket and slinger and use Tool 4201 to drive pinion shaft and rear bearing out of housing. Remove tool and front bearing, then use Tool 4628–D to remove rear bearing cup and shims. *NOTE – Check and record number and thickness of original shims so they may be reinstalled in their original position.* With forward end of housing up, use Tool 4628–B and remove front bearing cup. If necessary, press rear bearing from drive pinion with Tool 4621–BA. Wash all parts except wheel bearings in solvent and blow dry with air.

Inspection: Gears – Examine gears for scoring or signs of excessive wear. Check wear of splines, thrust surfaces and thrust washers.

Bearing Cups – Check cups for rings, scores, galling, or erratic wear patterns. Pinion bearing cups must be solidly seated. Check by trying a .0015" feeler between cups and bottom of bores.

Bearings – Check for scoring, galling, or overheating and check roller ends for wear.

CONTINUED ON NEXT PAGE

LINCOLN & CONTINENTAL HYPOID (Continued)

Bearing Caps – Check for wear and to see if bearings have been moving inside caps.

Universal Joint Flange – Make sure ears of flange have not been damaged and that end of flange which contacts oil slinger is smooth.

Housing – Check for damage and inspect all bearing bores for smoothness. Remove any nicks or burrs from mating surfaces of carrier housing. Check threaded holes for damage.

Differential Case – Make sure bearing hubs are smooth and that thrust surfaces of case are not damaged.

Reassembly: *NOTE – Ring and pinion gears are a matched set. If replacement is necessary, both gears must be replaced.* Place a thrust washer over each pinion and side gear, then assemble pinion and side gears in differential case and secure with pinion shaft. *NOTE – Lubricate all parts with axle lubricant during reassembly.* Slide side gears and thrust washers tight against pinion gear and check clearance between case and thrust washers with a feeler gauge. Clearance should not exceed .015". If greater, install new thrust washers. Align lock pin hole in pinion shaft with hole in case and install lock pin, then peen case metal over lock pin. Install ring gear and tighten bolts to 50–60 ft. lbs. *NOTE – If tooth contact pattern was not correct as determined at disassembly, or if new parts are being installed (including bearings), pinion depth and ring gear-pinion backlash must be adjusted (see below).* Start rear bearing on pinion (tapered end up), then use Tool 4621–A and press bearing on pinion shaft. Use a .0015" feeler gauge between bearing and pinion to make sure bearing is fully seated. Place shim pack (same thickness removed at disassembly) in rear bearing counterbore and drive rear bearing cup into housing with Tool 4628–A. With front end of housing down, then place dummy bearings, Tool 4205–C on case assembly and install assembly in housing. Install bearing caps in their respective position with bearing bolts finger tight. Install dial indicator, Tool 4201–A on housing with contact point against back side of ring gear. Apply pressure to both sides of ring gear and move the entire assembly as far as it will go in one direction. Adjust indicator to zero, then apply pressure to both sides of ring gear and move entire assembly as far as it will go in opposite direction. Record the amount of travel for use later in assembly. Remove dial indicator and differential assembly and remove dummy bearings. With forward end of housing upward, install front bearing cup with Tool 4616. Place housing in a horizontal position and install drive pinion and rear bearing assembly. *NOTE – If depth adjustment of pinion is required, see "Pinion Depth Adjustment" below.* With pinion adjusted to its correct depth, place shims (removed at disassembly) over forward end of shaft, then lubricate front bearing and install it on shaft (tapered end down) with Tool 4858–B. Use Tool 4858–G or J and tighten nut on tool to 180–200 ft. lbs. Check pinion bearing preload *(see "Pinion Bearing Preload Adjustment" below).* If necessary, readjust shim pack. Place oil slinger (concave side up) against bearing, then install gasket. Drive a new seal into position in housing with Tool 4676. Drive a new seal deflector into position on companion flange with Tool 4859, then start companion flange on drive pinion and press it into place with Tool 4858–B. Install washer and locknut and tighten nut to 180–200 ft. lbs. Install differential case with dummy bearings in housing and check backlash *(see "Backlash Adjustment" below),* then remove case and dummy bearings from housing. Install selected shim pack under each of the side bearings and press side bearings on case with Tool 4222–K. Attach spreader, Tool 4000–A on housing and spread housing opening enough to permit installation of differential case and bearing assembly. *CAUTION – Do not spread opening more than .015".* Install bearing caps in their correct positions as marked on caps and housing. Remove spreader, then place sealing compound on bearing cap bolts and tighten bolts to 70–90 ft. lbs. Check backlash with a dial indicator mounted on housing. Backlash should be between .003" and .008" and must not vary more than .002" between points checked at four positions around ring gear. Install gasket and cover with identification tag beneath one of the cover bolts. Refill housing with gear lubricant, Part No. B9L–19A508.

PINION DEPTH (With Gauge Assembly 4020–B): Install gauge shaft and micrometer assembly in differential housing, then install bearing caps and tighten bolts to 70–90 ft. lbs. Attach anvil clamp to differential housing *(see "Pinion Depth Gauge Installation Change" above).* Place anvil block on pinion and tighten anvil block clamping screw. Check micrometer depth reading and refer to calibration chart. Select reading that applies to pinion drive being used. If micrometer reading is greater than that specified in chart, it will be necessary to remove .001" in shim stock for each .001" difference between micrometer reading and that specified in chart. If micrometer reading is less than that specified in chart, it will require the installation of .001" in shim stock for each .001" difference between micrometer reading and that specified in chart. Service shims are available in .0025"-.0035", .0045"-.0055", .009"-.011", and .027"-.033". Remove checking gauge. If shim adjustment is required, remove rear pinion bearing cup and install or remove shims as required. Recheck pinion depth.

Shim Method: If a new pinion is to be installed, refer to gear end of old and new pinions for a "plus" or "minus" sign followed by a number. If marks are not present, the shaft is considered "zero". The amount of shims required for a new pinion can be determined by amount of difference between markings on old and new pinion (unless tooth contact pattern previously taken indicated improper pinion depth adjustment). For example: If old pinion marking was +2 and the new pinion is −1, a difference of .003" is noted. If original shim pack totaled .035", it will be necessary to add an additional .003" shim to bring −1 pinion in line with old +2 pinion. *NOTE – If pinion markings were reversed, it would be necessary to deduct .003" in shims from original, making a total of .032".* Place shim pack in rear bearing counterbore and drive rear bearing cup into housing.

PINION DEPTH CHART

Gear Ratio	No. of Teeth on Ring Gear	No. of Teeth on Pinion	+10	+9	+8	+7	+6	+5	+4	+3	+2	+1	0	−1	−2	−3	−4	−5	Pinion Marking
2.89:1	55	19	.865	.866	.867	.868	.869	.870	.871	.872	.873	.874	.875	.876	.877	.878	.879	.880	Micrometer Reading
3.11:1	59	19																	

PINION BEARING PRELOAD: With pinion shaft depth properly adjusted and shaft installed in housing, place approximately .065" shims on shaft at forward end and install front bearing, pressing it into position with Tool 4858-B. With Tool 4858-G or J, tighten nut on tool to 180-200 ft. lbs. With pinion shaft in a vertical position, use Tool 4209 and check torque required to rotate drive pinion. Torque required should not be less than 8 or exceed 12 inch pounds when using original bearings. If new pinion bearings installed, a preload setting of 18-20 inch pounds is recommended. If torque is less than specified minimum, remove shims. If torque exceeds maximum specification, add shims. Service shims are available in .003", .005", .010" and .030".

BACKLASH (RING GEAR-PINION) & SIDE BEARING PRELOAD: With pinion shaft properly installed in case, install differential case with dummy side bearings in their respective positions and install bearing caps and tighten retaining bolts finger tight. Attach dial indicator (Tool 4201–A) to housing with indicator contact bearing against rear side of ring gear. Hold ring gear tight against drive pinion and adjust indicator to zero. Move ring gear away from pinion as far as it will go and record the dial indicator reading. Repeat this procedure and recheck reading. *NOTE – This reading represents total thickness of shims to be placed on ring gear side of differential.* Subtract this reading from reading obtained before pinion shaft installed in housing (see above), and add .015". *NOTE – This will give total thickness in shims to be placed on tooth side of ring gear.* For example: Total travel with pinion out of housing was .100" and with pinion in housing, travel is .050". This means that .050" must be placed on ring gear tooth side of differential carrier and the rest of the shims (.050") will go on opposite side. *NOTE – This will set case assembly at zero preload and backlash.* To correctly adjust preload and backlash add .015" to ring gear tooth side, making a total of .065". Remove dial indicator, then remove differential case from housing. Install proper amount of shims as determined above under each of the side bearings, then press bearings on case with Tool 4222–K.

NASH & RAMBLER HYPOID

Nash Rambler & Statesman (1954)
Nash Ambassador (1954)

►**REAR AXLE IDENTIFICATION TAG:** Ring and pinion gear ratio stamped on tag attached to axle housing by one differential housing cover bolt.

►***CAUTION—Tag should be kept with axle parts and re-installed when axle reassembled. Install new tag (furnished with gear sets) when axle ratios changed.***

►CHANGES, CAUTIONS, CORRECTIONS

DESCRIPTION: Semi-floating, hypoid gear, Torque Tube Drive with Coil Springs (All Models except Rambler), Hotchkiss Drive with Semi-elliptical springs (Rambler).

AXLE REMOVAL: ***See "Rear Axle" on car model page.***

PROPELLER SHAFT (RAMBLER): Removal—Loosen coupling nut on rear end of rear universal joint yoke, use soft hammer to tap universal joint and propeller shaft off pinion shaft.

Installation Caution—Make certain that universal joint yoke lined up with pinion shaft when tapping yoke on shaft, tighten coupling nut securely.

►*RAMBLER 108" WHEELBASE MODEL PROPELLER SHAFT REMOVAL & DISASSEMBLY:* **(Removal)**—Remove propeller shaft coupling nut from coupling and tap coupling off pinion shaft with a soft hammer. Remove nuts from propeller shaft center bearing retainer studs and disconnect cross member from support brackets at side rail. Remove cross member and propeller shafts from car.

TORQUE TUBE & PROPELLER SHAFT (EXCEPT RAMBLER): These units not same design on all models.

Statesman (Exc. Overdrive & Hydra-Matic) - Torque tube drive with rear end of propeller shaft connected to drive pinion by a "Slip Type" coupling.

Statesman (Overdrive Trans.) - Same as for synchro-mesh transmission except that two propeller shaft bearings used.

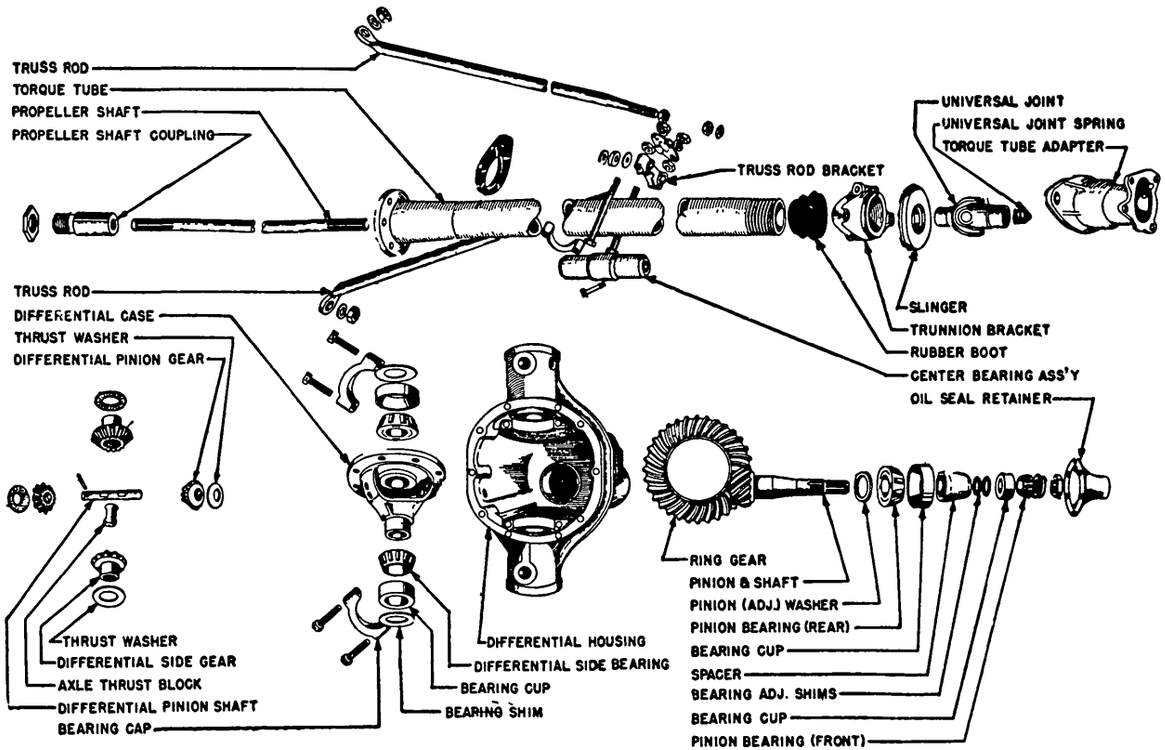
Statesman (Hydra-Matic)—Torque tube drive type with rear end of propeller shaft connected to drive pinion by flange type coupling (same as Ambassador). No propeller shaft center bearing used.

Ambassador (All Models)—Torque tube drive with propeller shaft connected to drive pinion by flange type coupling. Single propeller shaft center bearing (Exc. Hydra-Matic Drive Cars). No bearing used with Hydra-Matic Drive.

Removal: (All Models)—Disconnect truss rods at center bracket ("600" & Statesman); center bracket and axle housing (Ambassador). Pry universal joint off forward end of propeller shaft (joint is light press fit). Disconnect torque tube from rear axle housing, move tube forward to expose shaft coupling, loosen coupling nut or remove bolts from coupling flange, and lift off torque tube and propeller shaft.

Propeller Shaft Center Bearing (Not used On All Models): Prelubricated type ball bearing retained on propeller shaft by snap ring on each side and rubber mounted in torque tube. To remove bearing take out snap ring, drive bearing off **toward front end** of shaft (forward end of shaft .003" undersize to facilitate removal & installation). Install new bearing in same manner and see that new snap rings properly seated to hold bearing in position.

Propeller Shaft Coupling Installation (All "600" & Statesman Models with "Slip-Type" Coupling): Install propeller shaft oil seal Part No. 3138146, on propeller shaft. Butt the propeller shaft at forward end against a wood block and drive the coupling Part No. 3138142 on propeller shaft with a lead or soft face hammer. Tap retainer and oil seal on coupling (CAUTION—Do not install seal and retainer on coupling prior to its installation on propeller shaft as seal will be damaged). Coupling must be driven on propeller shaft to the shoulder or splined area inside coupling. Install Spacer, Part No. 3138466. Install torque tube rear oil seal Part No. 3138166, and retainer Part No. 3138144. Propeller shaft with coupling can now be installed on pinion shaft. Lubricate ground surface on coupling and torque tube rear oil seal with rear axle lubricant. DO NOT CRIMP LIP OF SEAL.



Torque Tube Trunnion Bracket ("600" & Statesman): On front end of torque tube and must be properly installed and adjusted when rear axle installed on car as follows:

Trunnion Bracket Adjustment—With axle completely assembled (rear end of propeller shaft against pinion shaft, torque tube assembled on housing), position trunnion bracket on torque tube so that front end of propeller shaft projects ⅛" to ¼" beyond the face of trunnion bracket. After bracket properly positioned, adjust clampscrew on underside of bracket to remove all excess clearance between threads on bracket and tube without setting up excessive friction. Bracket must be free to move on threaded tube. Lock clampscrew nut with cotter pin. Rubber boot must be installed behind bracket to protect threads on tube from road dirt. Threaded parts require no lubrication except at time of assembly. Lubricate these parts sparingly.

►***CAUTION—If propeller shaft extends less than ⅛" beyond face of trunnion bracket, universal joint slinger may rub on bracket. If shaft extends more than ¼", effectiveness of slinger will be reduc d.***

Trunnion Bracket Installation on Car: After bracket position adjusted (above), torque tube and rear axle assembly can be assembled to transmission as follows: Thread 2 special trunnion bracket studs (with tapered ends to rear) on trunnion bracket and lock with nuts and lock washers. Assemble plain stamped steel retainer, rubber cushion block (with small extension to front), steel retainer with pilot flange over extension on rubber block, on each stud. Install torque tube and rear axle assembly with trunnion bracket studs passing through holes in transmission (or overdrive) rear bearing retainer. Assemble steel retainer with pilot flange to rear, rubber block with extension to rear, and plain steel retainer on front end of studs. Tighten retainer nuts on studs until rubber cushions held under slight tension. Lock nuts with 'palnuts'.

CONTINUED ON NEXT PAGE

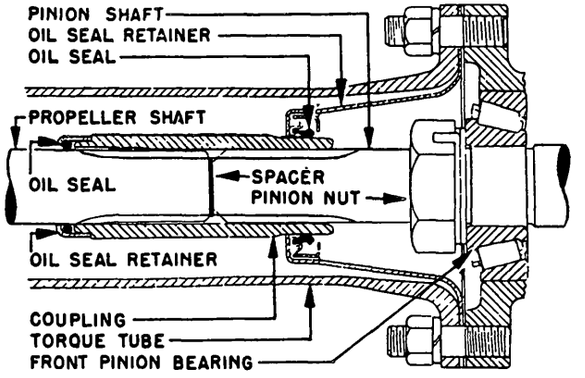
NASH HYPOID GEAR AXLE (TORQUE TUBE DRIVE)

NASH & RAMBLER HYPOID (C nt.)

REAR AXLE OVERHAUL: With torque tube and propeller shaft removed (see above), use stand to support axle and proceed as follows:

Disass mbly (Differential Removal): Mark bearing caps to insure correct reassembly, then remove bearing caps and pry differential assembly out of housing being careful not to damage bearings or shims.

Differ ntial Installation - Place bearing cups and shims in position on bearings, then tilt bearing cups slightly so that they enter seat in housing and force assembly into place, which will cause bearing cups to straighten on bearing rollers. If shims project, tap them into place, then install bearing caps and tighten bolts securely.



Pinion Bearing Disassembly: Before pinion shaft can be removed, propeller shaft must be disconnected by loosening coupling nut on rear end of shaft. Then remove the oil seal from housing, bend back lip of pinion nut locking plate, loosen nut. On Ambassador models, remove nut on forward end of pinion shaft at coupling flange, pull coupling flange from shaft, lift off oil seal (held in place by torque tube flange).

Pinion Disassembly—Tap on pinion shaft with soft hammer to loosen front bearing cone, remove bearing cone and roller assembly, remove shims located behind bearing cone, **note number and thickness of these shims** which control bearing adjustment. Remove pinion and rear bearing assembly through rear of housing. Use long drift to drive pinion bearing cups from housing (recess provided behind each cup for this purpose). Use pinion bearing tool J-2244 (600 & Statesman), tool J-2245 (all Amb. models) to remove rear bearing from pinion shaft, **note number and thickness of washer or shims on shaft behind bearing** which control pinion setting (gear mesh). To remove differential side bearing cone and roller assemblies, use special puller J-2497 being careful that puller does not contact roller cage or damage shims in back of left hand bearing (these shims control ring and pinion gear backlash).

Pinion Bearing Reassembly: Assemble each model as follows:

Rambler—Install pinion, shims, and rear bearing) through rear of housing, then install bearing adjusting shims (same thickness as were removed when axle disassembled) and front bearing on forward end of shaft. Install bearing washer and pinion nut but **do not install oil seal,** tighten pinion nut to 90-95 ft. lbs. Check and adjust bearing pre-load. After bearing adjustment completed, lock pinion nut to prevent loosening, install oil seal (use installer J-4485).

All Models except Rambler—Bearing adjustment controlled by shims on the pinion shaft between spacer and forward cone (A production change in late 1950 eliminated the spacer. Shims are placed between front bearing and shoulder on pinion shaft). When installing pinion, install correct washer and shim pack for correct pinion mesh (see Pinion Setting below) on shaft against pinion, install rear bearing cone and bearing spacer. Install sufficient shims on shaft in front of spacer (or against shoulder) to insure positive endplay of shaft when installed in housing, install front bearing cone, shaft coupling flange (Ambassador) or special tool (splined sleeve) and tighten nut on shaft securely. Then check bearing adjustment as directed below. NOTE—Do not install oil seal until adjustment has been made.

STATESMAN "SLIP TYPE" PROPELLER SHAFT COUPLING

Pinion Bearing Pre-load Adjustment:

Rambler Bearing Pre-load—Pre-load controlled by shims on pinion shaft behind front bearing cone. use two shims only, varying thickness of each shim to secure total thickness of .106" to .138" for correct .003" tight bearing adjustment and 12-14 in. lbs. pre-load. If pre-load less than 12 in. lbs., decrease shim thickness. If pre-load greater than 14 in. lbs., increase shim thickness.

►**Bearing Adjusting Shim Note**—These shims furnished in following thicknesses (combination of two shims provide range of .106" to .138" in .001" steps): .053", .054", .056", .058", .059", .063", .064", .066", .068", .069".

All Models exc. Rambler Bearing Pre-load (Tool J-2496: With pinion installed in axle housing (make certain that spacer and bearing adjusting shims in place on shaft between bearing cones), install tool on end of shaft in place of the coupling flange, tighten pinion shaft nut securely. Attach spring scale to exact center of tool handle (will provide 6" arm), check torque required to turn pinion shaft. See table below for desired torque reading. **If less than lower figure, remove shims from between spacer and front bearing cone, if greater than higher figure,** add shims at this same point. When bearing adjustment completed, install new oil seal, install coupling flange (Ambassador), see that pinion nut tightened to 105-110 ft. lbs.

Pinion Bearing Pre-load

Model	Pinion Shaft Turning Torque
Rambler & Statesman	12-14 in. lbs.
Ambassador	15-20 in. lbs.

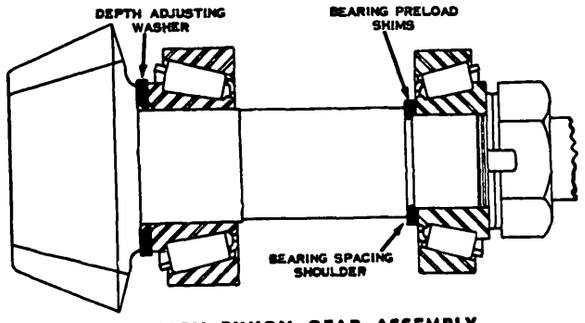
Pinion Setting: Pinion depth and consequent ring and pinion gear mesh is controlled by spacer washer or shims installed on pinion shaft between rear bearing cone and pinion. Must be adjusted when new gears or other parts installed.

Pinion Setting without Gauge—If new pinion being installed and pinion setting gauge not available, note washer and shim thickness used for old pinion, secure standard washer thickness for this housing by adding (if pinion marked +), subtracting (if pinion marked —) shims equal to figure following this plus or minus mark on the old pinion, finally correct this standard washer thickness in accordance with new pinion marking as directed under Pinion Setting above.

Pinion Setting using Rear Axle Drive Pinion Gauge No. J-2499: With rear pinion bearing cup installed in housing, place bearing cone and roller assembly in cup, press in and revolve bearing cone so that rollers are properly seated. Bolt special gauge plate on bearing cone (thread bolt through housing and secure in place with cross-piece and thumbnut at forward end), make certain that gauge plate does not contact housing at any point. Mount dial indicator on tool with indicator button on top of gauge pin, set dial indicator at Zero with tension on gauge pin. Install tool in axle housing with larger diameter of adapter rings seated in side bearing seats (install adapters on tool with larger diameter rings outward for Ambassador, small diameter outward for 600). Swing gauge point across gauge plate and note highest reading of dial indicator, subtract this reading from .140" and resulting figure will be washer thickness required for a standard "0" pinion. If pinion is not standard (marked by — or + figure on end), add (if pinion marked —), or subtract (if pinion marked +) from the standard washer thickness an amount equal in thousandths to the figure following this — or + sign.

Differential Disassembly: Use Puller Tool J-2497 to remove bearing cone and roller assemblies from differential case. Note number and thickness of shims located behind each bearing cone. These shims control ring and pinion gear backlash and differential bearing preload. Remove capscrews attaching ring gear to differential case (be sure and mark ring gear and case to retain same location when reassembled). Using a brass drift, tap ring gear from case. (CAUTION—Do not chisel or wedge ring gear from case). Use a 3/16" diameter drift at least 3" long to drive out the lock pin holding differential pinion shaft in place. Pinion shaft can then be removed, and the thrust block can then be dropped out through differential side gear. Roll differential pinion gears around on side gears until they can be lifted out through holes in case, then lift out side gears and thrust washers.

Inspection: Clean all parts and blow dry with air. Check gears for worn, cracked, chipped, or scuffed teeth. Check thrust washers and oil seal surfaces for wear or roughness, and check bearings for roughness or wear. Replace defective parts.



Differential Reassembly: Install thrust washers on side gears, with oil pocket toward gear, and install gears in bores of differential case. Install thrust washers behind differential pinion gears and mesh gears with side gears so the holes are opposite and in line with each other. Roll gears around until gear holes are aligned with differential pinion shaft hole in case. Install pinion gear shaft with the lock pin hole in line with the lock pin hole in differential case. Before pressing differential pinion shaft in place, install the thrust block through side gear, aligning hole in block with differential pinion shaft. Press differential pinion shaft in place and measure the clearance between differential side

C NTINUED N NEXT PA E

NASH & RAMBLER HYPOID (Cont.)

gear and case. This clearance should not be more than .010" (side gears should not fit tight enough to require more than 8 ft. lbs. to turn differential gears). Check by installing on axle shaft and using a torque wrench to turn shaft. Drive lock pin in place. Press differential side bearings on case using Tool J-2104 (Ambassador); J-2100 (Statesman).

Differential Bearing Adjustment: Bearing preload should be .004-.006" which is controlled by shims placed between side bearing cups and axle housing on each side. To determine shim thickness, install carrier in housing with one .075" shim at each side, then check endplay. If endplay noted, install next thicker shim on each side and recheck. With endplay just taken up, **install .005" thicker shim on right hand side** which

NASH PINION GEAR ASSEMBLY

will provide correct bearing preload of .004-.006". Tighten bearing capscrews to 55-60 ft. lbs. Check ring gear backlash with a dial indicator, then finally check ring gear and pinion mesh by painting gear teeth with red lead and rotating gears to provide a contact pattern. *NOTE - Adjusting shims are furnished in .075", .080", .085", .090", .095" thickn sses.*

Ring & Pinion Gear Adjustment: Gear mesh should be correct if pinion setting properly made (see above). Check gear mesh after all adjustments made by painting 8-10 teeth of ring gear with red lead and rotating gears by hand (turn pinion shaft with wrench while supplying drag on ring gear with the hand). Check backlash and adjust as follows:

Ring Gear Backlash Adjustment - Should be .004-.006". Adjust by adding or removing shims between left hand differential bearing cup and housing. *CAUTION - Total shim pack must not be changed and any shim chang on left hand side must be ffset by corr sp nding shim change on right hand side (t maintain bearing pr load).*

ℂ - From start of production to Serial No. A-11269.

►CHANGES, CAUTIONS, CORRECTIONS

►*REAR AXLE IDENTIFICATION TAG:* Ring and pinion gear ratio stamped on tag attached to axle housing by one differential housing cover screw. *CAUTION - Tag should be kept with axle parts and reinstalled when axle reassembled. Install new tag (furnished with gear sets) when axle ratio changed.*

►*REAR AXLE ASSEMBLY NOTE:* The assemblies used on all series cars are similar and overhaul procedures are the same except as noted.

►*1955 HUDSON HORNET V8 & NASH AMBASSADOR V8 PROPELLER SHAFT NOISE CORRECTION & PRODUCTION CHANGE:* A noise developing at 58-62 MPH, under light throttle pressure, either on pull or coast (similar to rear axle gear noise) may be caused by drive shaft and can be corrected by installing a two-piece shaft Part No. 3145400. The later two-piece shaft replaced the former one-piece type shaft in production at Car Serial No. V-8235 (Nash), Y-5887 (Hudson).

►*1956 PINION DEPTH SHIMS LOCATION CHANGE & DEPTH ADJUSTMENT PROCEDURE CHANGE:* In early production cars, the pinion depth adjusting shims were located between the pinion gear and rear bearing cone. In later cars the shims were located in the carrier housing behind the rear bearing cup. On later cars the rear face of the pinion gear is machine ground and the depth adjusting procedure changed. *See "Pinion S tting (Lat r Cars)" und r "Ov rhaul" below.*

►*1956 & EARLIER SERIES 50, 60, 80 TORQUE TUBE TRUNNION ASSEMBLY SERVICE REPLACEMENT:* Torque Tube Trunnion Kit, Part No. 3117235 containing a trunnion and six rivets is available for service replacement. For installation procedures, see "Overhaul" below.

►*1956 HUDSON HORNET & NASH AMBASSADOR V8 REAR AXLE NOTE:* A "Spicer" type rear axle is used on these models. *See "Spicer Semi-Floating" Rear Axle.*

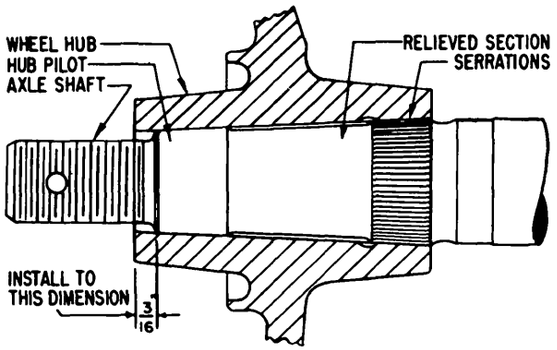
►*1957 RAMBLER V8 REAR AXLE PRODUCTION CHANGE:* Spicer type rear axle used beginning with Serial No. A-11296. Spicer type axles are identified by number "44" cast on housing.

►*1957 RAMBLER SIX AXLE SHAFT PRODUCTION CHANGE:* Beginning with Serial No. D-393951, serrated type axle shafts and hubs used in production, replacing the earlier "Keyed" type shaft and hub and drum assembly. *See below.*

DESCRIPTION: Semi-floating hypoid gear type with torque tube drive and coil springs (Exc. Rambler), Hotchkiss Drive and semi-elliptical springs (Rambler).

REAR AXLE REMOVAL: *See "Rear Axle" on Car Model Page.*

AXLE SHAFT: Removal (Key Type) - Remove wheel, use puller J-1644-B or J-736-B attached to rear wheel hub, remove hub from axle *(CAUTION–Do not use "knock-out" type axle pullers).* Check axle shaft endplay using Endplay Checking Tool J-2092 and note endplay for use at reassembly. Remove capscrews attaching brake support plate to axle tube. Slide oil seal, support plate and shims off axle (the oil seal on Rambler Models is located between support plate and axle tube). Measure shims with a micrometer to determine amount to be used at reassembly. Attach Axle Shaft Puller J-2498-A to axle and pull shaft out of housing. Slip bearing cup off axle and press bearing cone off axle shaft.



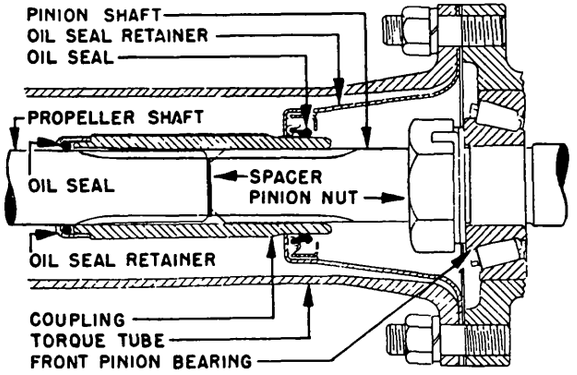
Installati n: Press axle shaft bearing onto axle shaft with small diameter of cone toward outer tapered end of shaft using Replacer J-2995. Soak new inner axle oil seal in light engine oil and install seal using Replacer J-2539. Install axle shaft, indexing splined end with differential side gears *(NOTE–Horn t & Ambassador right hand axle shaft is 1½" long r than l ft hand shaft).* Install outer bearing cup using Replacer J-1433-1. Install original shims onto axle with the drain holes aligned with hole in axle tube (if endplay was checked at time of disassembly and required correction, adjust the shim pack as necessary for correct axle shaft endplay of .002-.004"). Install brake support plate, spacer and oil seal (Rambler oil seal is installed behind brake support plate). Tighten support plate bolts to 50-55 ft. lbs. (Hornet & Ambassador), 30-35 lbs. (Other Series). Check and adjust axle shaft endplay (see below). Inspect wheel hub key for a snug fit in keyway of shaft and hub. *(NOTE–On* Rambler, install wheel hubs after axle assembly installed in car). Slide hub onto axle shaft aligning the keyways. Install key and press hub onto shaft. Key must be flush with hub. Install thrust washer and axle nut and tighten to 180-190 ft. lbs. (Hornet & Ambassador), 160-165 ft. lbs. (Other Series). Install cotter pins.

Replacement (Serrated Type): Remove the tire and the wheel assembly from the brake drum and hub, then remove speed nuts holding drum to hub. Use Hub Puller, Tool J-736-B or J-1644-B to remove hub from axle shaft. To install hub, index serrations of hub with those on shaft and tighten with the axle shaft nut and washer. The hub is properly located on axle shaft when the measurement from outside face of hub to the taper of the axle shaft is 3/16". *(CAUTION - Ov r-tightening beyond this dim nsion will cause int rf r-ence between drum and brak support plat).*

►*SERVICE REPLACEMENT HUB NOTE:* Service replacement hubs are not serrated. Serrations will be cut in the hub when it is installed on the shaft. The measurement of 3/16" from outside face of hub to the taper of the axle shaft applies to a service replacement hub without serrations.

CONTINUED ON NEXT PAGE

1955-57 HUDSON, NASH, RAMBLER HYPOID (C nt.)



RAMBLER (6 CYL.) SERRATED AXLE

TORQUE TUBE & PROPELLER SHAFT (Exc. Wasp & Stat sman with Standard & Overdrive Transmission): R m val—Raise and support rear end of body. Disconnect hand brake cable at equalizer and remove hand brake bellcrank assembly from torque tube. Disconnect rear stabilizer bar at rear axle tube. Remove truss rods at axle tubes and at center bracket on torque tube. Disconnect torque tube from transmission adapter and move axle assembly and tube to the rear to disengage propeller shaft from transmission. Disconnect rear of torque tube from rear axle housing and move tube forward sufficiently to expose coupling. Disconnect coupling flange and remove torque tube and propeller shaft. Remove pinion flange with Puller J-2984.

Installation—Reverse removal procedure and note the following: On Hornet & Ambassador use new locks on companion flange nut. On Wasp, support pinion from the rear while pressing on companion flange. Tighten flange nuts to 30-35 ft. lbs.

TORQUE TUBE & PROPELLER SHAFT (Wasp & Statesman with Standard & Ov rdrive Transmission): Removal—Raise and support rear end of body. Disconnect hand brake cable at equalizer and remove hand brake bellcrank assembly from torque tube. Disconnect rear stabilizer bar at rear axle tube. Disconnect truss rods at center bracket. Disconnect trunnion bracket from the adapter by removing rear nuts from dowel studs. Move torque tube and rear axle to rear to clear studs. Disconnect torque tube from rear axle housing and move tube forward. The coupling is a slip fit on the pinion shaft and a press fit on the propeller shaft. Slide coupling off pinion shaft. Place propeller shaft in a vise and drive coupling off shaft with a lead hammer.

Installati n—Reverse removal procedure and note the following: Install propeller shaft oil seal and retainer on propeller shaft. Butt propeller shaft at forward end against a wood block and drive the coupling on the shaft with a lead hammer. *(CAUTION*—Do not install the seal and retainer on the coupling prior to its installation on the propeller shaft). Coupling must be driven on shaft to the shoulder on the splined area inside coupling. Install the spacer. Lubricate the ground surface on the coupling and the torque tube rear oil seal with rear axle lubricant. The propeller shaft with coupling can now be installed on pinion shaft (do not crimp lip of oil seal). Make sure that the torque tube seal contacts coupling on the ground surface of coupling.

"SLIP TYPE" PROPELLER SHAFT COUPLING

PROPELLER SHAFT (Rambler 100" Wheelbase & 108" Wheelbase with Hydramatic): Removal—Raise and support rear of body at the side sills and the rear axle at center of housing. Loosen propeller shaft coupling using Propeller Shaft Coupling Wrenches J-4486. Disconnect rear shocks at the axle tubes, hand brake cable at adjusting yoke, and rear brake hose clip from body floor pan. Remove rear spring front bracket attaching nuts and lower the rear axle, continuing to support the body, thus lowering rear spring front brackets from the floor pan. Move axle assembly to the rear sliding propeller shaft yoke of transmission main shaft splines. Remove propeller shaft from pinion shaft.

Installation—To permit correct location of propeller shaft when assembling on the car, slide shaft onto transmission main shaft until it is bottomed. Mark propeller shaft front yoke adjacent to the oil seal and remove shaft. Install propeller shaft on rear axle pinion shaft. Move rear axle assembly to rear and slide the front universal joint yoke onto transmission main shaft. Loosen rear spring front eye bolt and tilt front bracket so that rear holes are aligned with studs in floor pan. Raise rear axle assembly aligning rear spring front bracket with studs, and tighten. Reinstall brake hose clip, hand brake cable, and rear shocks. Permit rear axle assembly to hang freely, the shocks fully extended, and move the shaft to the front or rear to locate the mark on the propeller shaft 5/32" to rear of transmission oil seal. Tighten coupling nut to 300 ft. lbs.

PROPELLER SHAFT (Rambler 108" Wheelbase with Standard & Overdrive Transmission): Removal—Remove propeller shaft coupling nut from coupling and tap coupling off pinion shaft splines with a soft faced hammer. Remove nuts from propeller shaft center bearing retainer studs. Disconnect crossmember from support brackets at side sills and remove crossmember. Remove assembly from car. Place propeller shaft in a vise and turn back propeller shaft bearing lock to allow propeller shaft center locknut to be removed. The rear shaft can now be removed by sliding the splined slip joint from front propeller shaft, (the locknut will remain on splined slip joint). Remove felt washer and felt washer retainers, and remove the nut. Remove propeller shaft center bearing spacer, cover, center bearing and retainer, bearing cover, and dust shield. Remove center bearing from retainer with a brass drift.

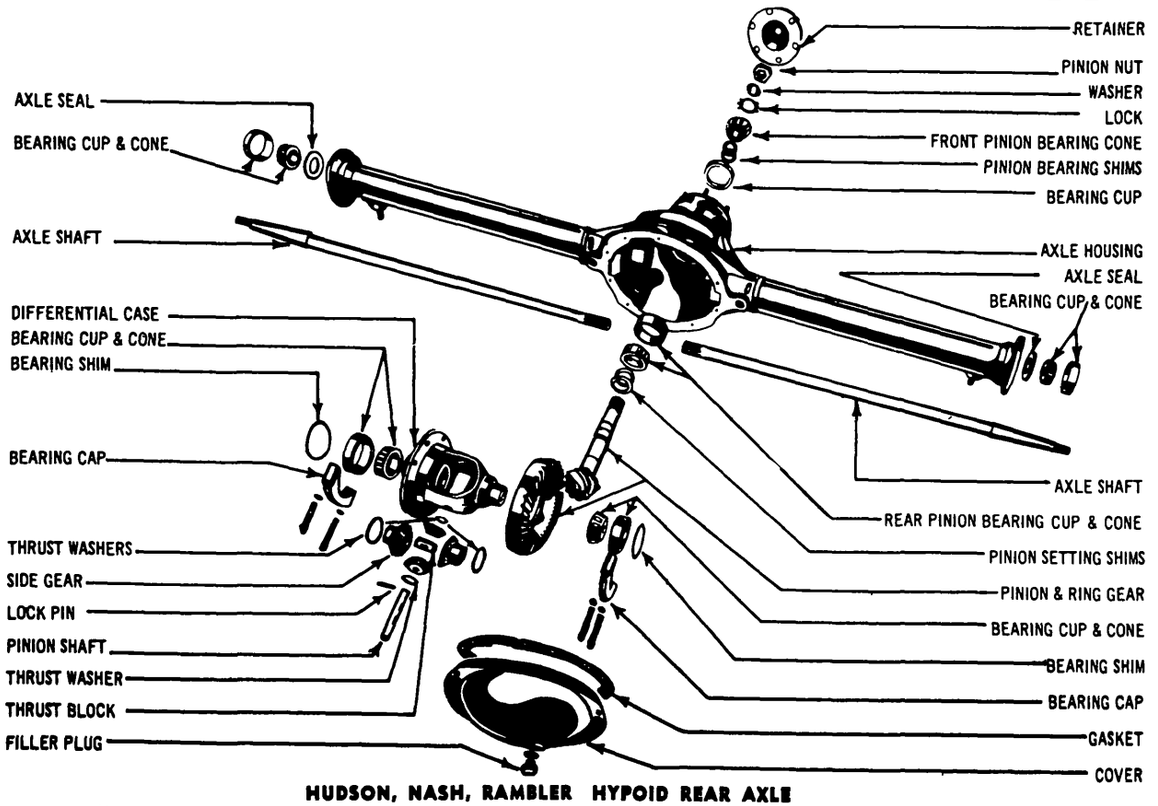
Installation—Reverse removal procedure and note the following: Yokes of universal joints must be in alignment when installed.

TORQUE TUBE TRUNNION BRACKET ADJUSTMENT (Wasp & Statesman): Tighten trunnion bracket clampscrew enough to remove excess clearance without setting up friction and so trunnion bracket is free to move on torque tube. When rear end of propeller shaft is against pinion shaft and torque tube is secured to axle housing, the front end of the propeller shaft must protrude from 1/8" to 1/4" beyond front face of trunnion bracket (except Hydra-Matic Drive models). On Hydra-Matic Drive models, adjust trunnion bracket so forward edge of dust shield is in alignment with centerline of universal joint bearing cups. Connect bracket bolts to transmission adapter.

REAR AXLE OVERHAUL: With rear axle assembly removed from car and with axle shafts removed, proceed as follows:

Differential Removal & Disassembly: Remove cover bolts (note ratio tag on one of bolts which should be retained for installation after overhaul), mark differential side bearing caps with a center punch to assure correct reassembly, and remove bearing caps from housing. With a pry bar inserted from each side of differential case adjacent to pinions, pry against housing and lift case assembly out. *(CAUTION*—Take care to prevent damage to bearings and shims) Tie side bearing shims to their respective bearing caps and cups to prevent misplacement. Install Bearing Puller J-2497 on bearings in such a manner as to leave rollers free, and remove bearings from case. Remove capscrews attaching ring gear to differential case, and using a brass drift, tap ring gear from case. *(CAUTION—Do not chisel or wedge the ring gear from case).* Use a 3/16" diameter drift at least 3" long to drive out the lock pin holding differential pinion shaft in place Drive out pinion shaft, dropping the thrust block out through differential side gear. Roll differential pinion gears around on side gears until they can be lifted out through holes in case, then lift out side gears and thrust washers.

Inspection—Inspect all parts for distortion, cracks, and excessive wear. Inspect all bearing surfaces for nicks and burrs and dress down small nicks or burrs with a smooth file or stone. Check fit of differential pinion shaft in case. Shaft should be a press fit to .010" loose. Inspect fit of differential side gears in differential case bore. This clearance should not exceed .007". Clearance between side gear and case should be .000" to .008" with .004" preferred. Where differential assembly is a tight fit, it will be acceptable if not more than 8 ft. lbs. of torque applied to either side gear will rotate the internal gears. If gears need replacement, pinion and side gears should be replaced as a set. Inspect ring gear and if tooth pattern indicates pinion and ring gear have not been meshing correctly, replace both gears. Inspect ring gear attaching bolts for elongation and replace any bolts that are defective.



CONTINUED ON NEXT PAGE

1955-57 HUDSON, NASH, RAMBLER HYPOID (Cont.)

Pinion Shaft Removal & Disassembly: Remove companion flange or coupling from pinion shaft (see "Torque Tube & Propeller Shaft" above). Tap end of pinion shaft slightly with a fibre hammer to free front bearing cone from pinion shaft and remove bearing. Retain shim located between bearing and shoulder on pinion shaft (this shim controls bearing preload) and tag it for use at reassembly. Remove pinion and shaft assembly from rear of housing. Drive bearing cups out of rear axle housing using a drift inserted in recess in housing. Keep cups square in the bore to prevent damaging bores. Remove rear bearing from pinion shaft using Pinion Bearing Remover J-2245-A (Hornet & Ambassadore), J-2244 (Wasp, Statesman & Rambler) and an arbor press. Remove pinion bearing adjusting washer located between bearing and pinion gear. Tag and retain this washer for use at reassembly (washer is used to adjust pinion depth in housing).

Inspection—Check to see that ring gear and pinion are matched sets (numbers or marks are etched in rear face of pinion gear and the edge of ring gear). Inspect oil seal surface for wear or roughness and pinion splines for damage caused by worn or loose coupling. Inspect pinion gear teeth. Inspect bearings, cones, cups and rollers for excessive wear, overheating, or scoring. If replacement required replace bearing cone and cup.

Differential Reassembly & Side Bearing Adjustment: Install new thrust washers on side gears with oil pockets on washer toward gear, and install gears in bores of differential case. Install new thrust washers behind differential pinion gears and mesh gears with side gears so holes are opposite and in line with each other. Roll gears around until gear holes are aligned with differential pinion shaft holes in case. Install pinion gear shaft with the lock pin hole in line with lock pin hole in case, partially into case. Install thrust block through side gear, aligning hole in block with pinion shaft. Press pinion shaft into place and measure clearance between differential side gear and case. This clearance should not exceed .008". (see "Differential Inspection" above to check tightness of side gears). Drive lock pin into place to secure pinion shaft. Press differential side bearings into place on case using Side Bearing Replacer J-2646 (Hornet & Ambassador), J-5364 and handle J-875-5 (Other models). Place bearing cup over each side bearing and install differential case assembly in axle housing (ring gear not installed on case and drive pinion not installed in housing). Install a .070" shim (Hornet & Ambassador), .075' shim (Other Series) on each side between bearing cup and housing. Test assembly for side play by rotating it, and install progressively greater shims to eliminate all side play. Hornet & Ambassador Series shims are available in thicknesses from .070" to .100" in .002" increments. Other Series are available in thicknesses from .075" to .098" in .002" increments. (*NOTE*—If additional thickness of shims is required to eliminate side play on Hornet & Ambassador, thin shims .003", .005", or .010" may be installed between bearing cone and differential case. For other series, use Hornet & Ambassador pinion depth adjusting shims in the same manner). When side play is eliminated, a slight bearing drag is noted. Install respective bearing caps and tighten cap bolts to 105-110 ft. lbs., (Hornet & Ambassador), 55-60 ft. lbs., (Other Models). Recheck differential for excessive bearing drag. Attach a dial indicator to axle housing and check ring gear face of differential case for runout. Runout should not exceed .002'. Remove case from housing, **retaining shims used to eliminate side play.** Install ring gear on differential case and bolt gear to case with capscrews and new locks. If necessary, two 3/8"-24X1" capscrews installed in opposite holes may be used as guides to pull gear into position. Tighten capscrews to 50-55 ft. lbs. and install locks.

HUDSON, NASH, RAMBLER HYPOID REAR AXLE

Pinion Shaft Reassembly & Installation: Install rear bearing cup in axle housing with Installer J-2533 (Hornet & Wasp), J-5367 (Other Series). Install front bearing cup with Installer J-2531 (Hornet & Ambassador), J-2532 (Other Series), being careful to drive all bearing cups straight into clean bores. Slide proper depth washer and new shims that have been selected (if old pinion and ring gear being reinstalled, use same washer and shims pack found under rear bearing at time of removal. If a new pinion and ring gear or new bearings being installed, adjust pinion depth as indicated below. *See "Pinion Setting").* Use bearing Installer J-2995 (Wasp, Statesman, Rambler) and press bearing tight against washer and gear. On Hornet & Ambassador, a piece of steel tubing 1 11/16" I.D. about 8" long may be used to install pinion gear assembly in housing. Install same thickness of shims as removed and install front bearing. If adjusting washer thickness was changed, add the necessary shims to compensate for the change. On Hornet & Ambassador use pinion holding and spacer tool J-2496 and install spacer in place of the companion flange. Tighten pinion nut to 125-150 ft. lbs. On other series, install pinion nut, thrust washer, and lockwasher. Tighten nut to 90-100 ft. lbs.

Pinion Bearing Preload: Install Pinion Holding Tool & Spacer J-2496 on pinion shaft. Attach a spring scale to center of handle and pull tool in a circular motion. Note reading on scale and multiply it by six to determine the inch pounds of torque required to rotate pinion shaft (*NOTE*—For a more accurate reading, turn axle up so pulling effort is on a horizontal plane). Pinion bearing preload is .15-18 inch pounds (Hornet & Ambassador), 12-14 inch pounds (Other Series). If preload is too high, **increase** shim thickness behind front bearing. If too low, **decrease shim thickness.** Complete installation as indicated below.

C NTINUED N NEXT PA E

1955-57 HUDSON, NASH, RAMBLER HYPOID (C nt.)

H rn t & Ambassador–Remove spacer tool and install a new oil seal. Install companion flange using Tool J-1375. Install lockwasher and pinion nut and tighten to 125-150 ft. lbs.

Wasp, Statesman & Rambler (Exc. Wasp with Hydra-Matic)– Install lockwasher next to bearing then the plain washer and nut. Tighten nut to 90-100 ft. lbs. Install pinion oil seal on Wasp and Statesman. Use Tool J-4485 to install pinion oil seal on Rambler.

Wasp (With Hydra-Matic)–Press pinion shaft companion flange onto pinion shaft while supporting shaft from the rear to prevent damage to bearings or axle housing.

►*PINION BEARING PRELOAD ADJUSTING SHIM NOTE:* A thickness range of .106" to .138" in .001" increments can be obtained by using a combination of two of the following size shims which are supplied for service installation. .053", .054", .056", .058", .059", .063", .064", .066", .068", .069".

Pinion Setting (With Pinion Setting Gauge J-2499): Place rear pinion bearing cone in bearing cup and revolve it using a little pressure to "set" the rollers. Bolt gauge plate over bearing cone so that it does not touch housing at any point (the bolt runs down through housing and is secured at pinion end). Attach a dial indicator to tool. With indicator button on top of the gauge pin, set dial indicator, under tension, to zero. Install tool with adapter squarely seated in side bearing bores in housing (Large diameter of adapter is used for Hornet & Ambassador, and small diameter is used for other models). Swing gauge point across plate until highest reading is obtained. This reading subtracted from a constant of .140" will give the standard adjusting washer thickness for that particular housing. Using this figure, add or subtract according to marking on pinion to determine correct adjusting washer thickness. For example: When gauge point is moved across plate and a reading of .015" is obtained, subtracting this figure from the constant of .140" will give a standard of .125". That means, using a standard "O" pinion, and adjusting washer of .125" thickness would be required. However, if pinion marking read -3 (meaning that it is .003" away from ring gear) it would be necessary to add this .003" to the standard. Thus the adjusting washer and shim combination would be .128".

Pinion Setting (With ut Pinion Setting Gauge): Note pinion marking on old pinion and new pinion gears and measure the thickness of the old depth washer and shims. Compensate for the difference in the old and new pinion markings and correct the depth washer and shim thickness. As an example: If old pinion is marked +2 and the new pinion is marked -3, there is a difference of .005" (indicating new pinion .005" further away from ring gear than old pinion). If old washer is .123", the new washer and shim pack must be .128". In In this case use a .125" washer and a .003" shim.

Pinion Depth Setting Adjustment (Later cars with pinion depth adjusting shims located between rear pinion bearing cup and bore in rear axle housing): The amount of shims used is determined by the amount of shims removed at disassembly and by the plus or minus figure etched on pinion. For example, if original pinion was marked + 2 and had a shim pack of .035" behind rear bearing cup and the new pinion to be installed is marked – 1, the shim pack must be increased by .003" to bring the new pinion to its correct position. Install the pinion front bearing cup with Replacer J-2534 or J-5367. Insert pinion in position and install front bearing cone and cup. Check pinion setting as follows: Mount discs J-2499-2 on Gauge Arbor J-6482-1 or discs J-5223-5 on Arbor Gauge J-5223. Install gauge seated squarely in housing bores. Place bearing caps in position and tighten bolts finger tight. Install Gauge Block J-5223-16 in position against end of pinion gear and clamp in place with Clamp Bar and Screw J-5223-6 and J-5223-14. Loosen thumb screw in end of gauge block and move plunger out until head contacts gauge arbor. Lock plunger in place with thumb screw, being careful not to disturb position of plunger. Loosen screw in clamp holding gauge block against pinion and remove gauge block. Measure distance from end of anvil to top of plunger head with a two to three inch micrometer. This measurement represents the distance from rear face of drive pinion to centerline of the rear axle and should be as follows: 2.095" (Rambler); 2.094" (Statesman & Wasp); 2.547" (Hudson Hornet & Nash Ambassador). This measurement applies only to correctly adjusted pinions marked "0". On a pinion marked + 2, the reading should be .002" less than this figure and with a pinion marked –3, the reading should be .003" greater. If the micrometer reading shows pinion setting is incorrect by more than .002" plus or minus from the given figure, shims equal to that amount must either be added or removed from shim pack between rear bearing cup and housing.

Ring Gear & Pinion Backlash Adjustment: Install differential assembly in housing using the shims selected to remove side play (see above). Tighten bearing caps to 105-110 ft. lbs. (Hornet & Ambassador), 55-60 ft. lbs. (Other Series). Attach a dial indicator to housing with the button contacting drive side of a tooth on ring gear and at right angles to it. "Rock" the ring gear and note dial reading. The backlash should be .002-.006" (.004" preferred). To increase backlash, install a thinner shim on ring gear side and a thicker shim on opposite side. To decrease backlash, reverse the procedure. *(CAUTION–Total thickness of shim pack must not be changed from those selected to remove all sideplay).*

Differ ntial Sid B aring Pr load: Increase shim pack (selected to remove sideplay) by adding a .004" to .008" thicker shim. These additional shims can be installed on one side only, or equally on both sides.

Diff r ntial Ass mbly Installati n: Assemble side bearing cups and shims on side bearings (make sure that bearing cups completely cover rollers of side bearings). Lower assembly into axle housing until bottom edge of bearing cups and shims are started in bearing bore. Keep differential assembly square in housing and push it down as far as possible. Using a soft hammer, tap outer edge of bearing cups until seated in housing *(CAUTION–Do not distort shims by hammering th m into housing).* Install bearing caps and tighten to 105-110 ft. lbs. (Hornet & Ambassador), 55-60 ft. lbs. (Other Series). Recheck ring gear and pinion backlash and correct as necessary. Coat eight or ten teeth of ring gear with red lead in oil and check tooth contact pattern. *See "Hypoid Gear Adjustment"* Install axle shafts.

Service Replacement Torque Tube Trunnion Installati n (Series 50, 60, & 80, 1956 & Earlier): *(NOTE* - On models prior to 1956, the trunnion assembly is riveted to torque tube. On 1956 models, it is welded). On 1956 models, remove original trunnion by making a hack saw cut through one thickness of metal adjacent to weld. Strike trunnion a sharp blow with a hammer to break away portions that may not have been cut all the way through. Remove trunnion and grind off remaining portion of weld on torque tube. On earlier models, remove rivets, then remove trunnion. Place new trunnion on torque tube, then place trunnion and torque tube assembly on bench and block tube at truss rod brackets or studs and position trunnion so that distance from front face of trunnion flange to rear face of rear torque tube flange is correct for the model being worked on (see "Torque Tube Lengths" below). *(NOTE* - Trunnion must be installed on torque tube so that the wider flat surface on trunnion flange is upward. When properly installed, the lower narrow flat surface on trunnion flange will be parallel to truss rod bracket (Series 50); truss rod studs (Series 60 & 80). Weld trunnion to torque tube (1956 models), or rivet to torque tube (earlier models). *NOTE* - If desired, the trunnion may be riveted to torque tube on 1956 models. Use trunnion as a template and mark the six holes located on torque tube. Drill 21/64" diameter holes and install trunnion with rivets supplied in kit. Rivet heads are installed to inside of torque tube.

Series	Torque Tube Lengths	① Length
50 (Std. & Overdrive)		61 1/32"
50 (Hydra-Matic)		63 31/32"
60 (Std. & Overdrive)		62 3/8"
60 (Hydra-Matic)		65 7/32"
80 (Ultramatic)		65 7/32"

① - Front flange face to rear flange face.

Torque Tube & Propeller Shaft Removal, Installation & Adjustment (Rambler Models): Procedures are the same as for 1955 Statesman & Wasp models except that on Rambler models with Hydra-Matic Transmission, the rear coupling is integral with the propeller shaft.

AXLE ASSEMBLY INSTALLATION: *S "T rqu Tub & Pr pell r Shaft" and "Axle Ass mbly R m val" ab v and rev rs th rem val pr c dur s utlin d.*

OLDSMOBILE HYPOID

All Models (1954-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*PINION BEARING PRELOAD CAUTION: Pinion bearing preload must be adjusted whenever universal joint flange nut on pinion shaft is loosened. Preload is controlled by this nut and will be disturbed when nut loosened for any reason.*

DESCRIPTION: Semi-floating hypoid gear type of own design.

REMOVAL OF AXLE: *See Rear Axle on Car Model Page.*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Model page.*

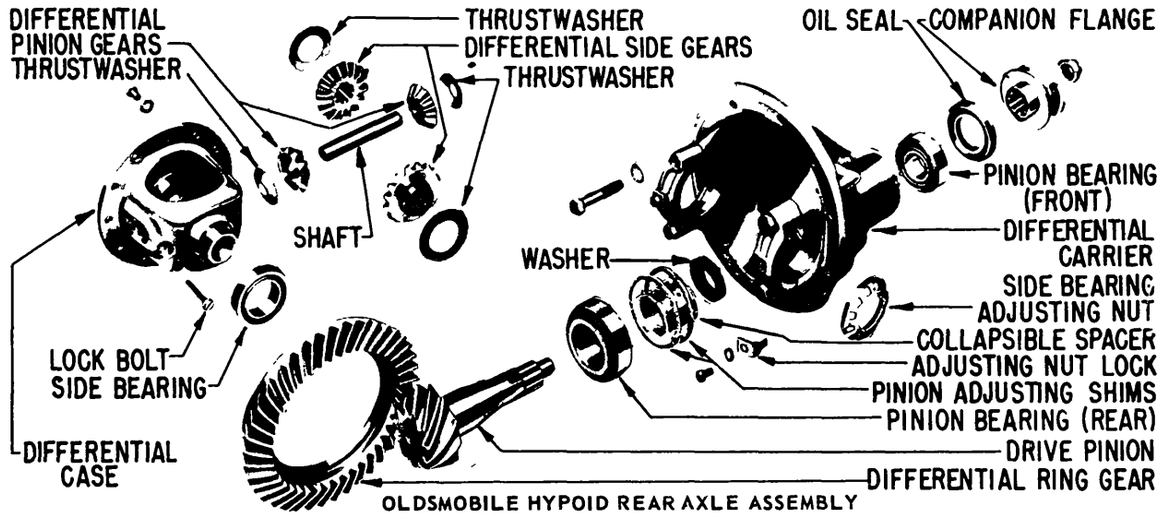
WHEEL BEARING & OIL SEAL REPLACEMENT: *(NOTE-* Wheel bearings have .012-.015" endplay between balls and the races. Do not reject bearing unless endplay is greater than .020" or if there is definite roughness between ball and race). With axle shaft removed, remove bearing retainer collar after splitting with a cold chisel. *(CAUTION* - Do not damage axle when removing collar). Using Tool J-947-2 and J-947-1, press off bearing in an arbor press. To install bearing, use Tool J-947-3 and Plate J-947-1 with an arbor press and press bearing over axle shaft, being sure that pressure is being applied to inner race of bearing. After bearing has been pressed firmly against axle shaft shoulder, press new bearing retainer collar on shoulder of shaft against bearing. Be careful not to damage shaft surface on which oil seal runs.

Oil Seal: With axle shaft removed, remove seal. Before installing a new seal, apply sealer around its outside diameter then install seal in housing with Tool J-5818. *CAUTION* - When installing axle shaft, be careful not to damage seal.

PINION SHAFT OIL SEAL REPLACEMENT: Mark pinion shaft nut before loosening so that it may be retightened to the exact same location. This will avoid necessity of resetting pinion bearing preload. Remove companion flange nut and washer, then remove companion flange with Tool 6295-01. Remove seal by driving it out of housing with a blunt chisel. Lubricate new seal and coat outer diameter with sealing compound. Tap seal into place using Tool J-5395. Apply seal lubricant, Part No. 567196 to outer diameter of flange and to lip of new seal. Install flange and tighten nut 1/16" beyond alignment mark.

OVERHAUL: Carrier Removal - Remove axle shafts, then clean area around carrier to prevent entry of dirt. Disconnect propeller shaft at rear universal joint and support shaft in body tunnel. Remove nuts from carrier mounting studs and move carrier away from housing sufficiently to drain the lubricant. Remove carrier from housing. *NOTE* - Do not wash carrier assembly until after it has been completely disassembled.

Carrier Disassembly: Mount carrier assembly in Holding Fixture, Tool J-3289-B. If original pinion and ring gear are to be reinstalled, install Dial Indicator, KMO-30 on carrier and measure backlash of ring gear at two points 180° apart. The lowest reading should be within .003-.012". Check tightness of ring gear to differential case cap screws which should be 55-60 ft. lbs. Mark the right side bearing adjusting nut, bearing cap, and carrier with two punch marks, then mark left side in same manner with one punch mark. *(NOTE- These marks will be used at reassembly if the original gear set is being used).* Remove bearing cap lock screws and locks, then check side bearing preload to determine if it is correct, as follows: Loosen each bearing cap attaching bolt ¼ to ½ turn (just enough to turn adjusting nut), then tap bearing lightly to assure freeness of nuts in threads. Back off right hand adjusting nut (right hand nut is opposite ring gear) and watch the outer race of bearing. *(NOTE* - If side bearing preload is correct, the outside bearing race should start to turn the instant the adjusting nut is loosened, and should continue to turn until adjusting nut is loosened 1½ to 3 notches. **Count and record the number of notches between punch marks on nut and those on carrier where race stopped turning**). Remove bearing cap bolts, bearing caps, and adjusting nuts. Remove differential case from carrier while holding outer bearing races against rollers. Check pinion bearing preload (see below), then turn carrier assembly to a horizontal position and remove companion flange nut, then remove companion flange with Puller J-6295-01 and Holding Tool J-6544. Remove drive pinion rear bearing and spacer as follows: Tap out front bearing with a plastic hammer, or if necessary, install carrier in an arbor press and press pinion out of front bearing. *NOTE* - In all cases, a shim washer .037" to .045" will be found between the compressible spacer and inner race of front bearing. A second shim is used in production to salvage the compressible spacer should recommended preload be exceeded. This second shim can be used in the same manner for service *(see "Compressible Spacer Note" below).* Remove oil seal by driving it out of housing with a blunt chisel, then remove front inner race and roller assembly. Press front bearing race out of carrier with Tool J-6198, and rear bearing race with Tool J-6533. Using Tool J-6531 and arbor press, remove rear bearing from pinion shaft.



Differential Case Disassembly: Remove lock screw and pinion gear shaft, then remove pinion gears, side gears and thrust washers from case. If ring gear or case are to be replaced, remove ring gear. *(NOTE* - Do not remove side bearings from case unless they are to be replaced). If necessary to remove side bearings use Differential Side Bearing Remover, Tool TR-278-R, with ends of puller placed in recess in case.

Differential Case Reassembly: Reverse disassembly procedure and note the following: Lubricate gears and thrust washers, then place side gear thrust washers over hubs and install side gears in case. While holding upper side gear up into its bore, position one pinion gear (without thrust washer) between side gears and rotate gears until pinion gear is directly opposite loading opening in case. Place the other pinion in position between side gears so that pinion shaft holes line up. Rotate pinion gears in position to assure pinion gear shaft holes in gears are lined up with shaft holes in case. If holes do not line up, pinion will require repositioning in side gear teeth. With gears properly meshed, rotate assembly just enough to permit working the pinion gear thrust washers into position between gears and case. Install gear shaft and lock it in place with lock screw and lockwasher.

Carrier Reassembly: Reverse Disassembly procedure and note the following:

Pinion Gear Setting - Before assembling the carrier, the correct number of shims required to locate drive pinion properly must be determined from markings on differential carrier and end of pinion. Carrier is marked on face of flange with either of the following codes: "D" (indicating "deep"); "S" (indicating "shallow"); "O" (indicating "standard"). The digit following the letter designates number of thousandths "deep" or "shallow". *NOTE - A carrier marked "O" will require .010" (1954-56), .016" (1957-60) of shims under pinion bearing, plus or minus the markings on pinion). Pinions are etched on gear end with marks "plus" or "minus" together with the number indicating in thousandths of an inch the shims required to position pinion in carrier. Drive pinions machined to zero specifications are not*

CONTINUED ON NEXT PAGE

OLDSMOBILE HYPOID REAR AXLE ASSEMBLY

OLDSMOBILE HYPOID (C nt.)

mark d. DISREGARD STAMPED NUMBERS ON END OF PINION SHAFT AT GEAR END. REFER TO "ETCHED" NUMBERS ONLY. Determine markings on carrier and on pinion, then refer to "Pinion Shim Chart" for correct thickness of shims to use.

►*PINION SHIM NOTE:* Pinion shims are furnished in the following sizes and are marked for identification as follows:

1954-56 Shims - .002" (Plain), .003" (Blue or Plain color or 1 hole), .004" (Copper or Plain with 2 holes), .005" (Plain), .010" (Plain).

1957-60 Shims - .004" (no notch), 005" (1 notch), .006" (2 notches), .007" (no notch), .008" (1 notch), .009" (2 notches), .010" (no notch), 013" (1 notch), .014" (2 notches), .015" (no notch), .016" (1 notch), .017" (2 notches).

Pini n Driv G ar Installation - Press rear pinion bearing race into carrier with Tools J-2940 & J-2937. Install front bearing race with Tool J-6133. Install correct number of pinion adjusting shims against shoulder of drive pinion shaft, then lubricate rear bearing and press it firmly against shims on pinion shaft with Tools J-2935 and J-358-1 and an arbor press. Place compressible spacer over pinion shaft (with large diameter against shoulder on pinion), then install washer. *(NOTE - S "Compressible Spacer Note" below).* Place drive pinion into position in carrier. Lubricate front bearing and install it over pinion shaft. *(NOTE* - If pinion shaft is a press fit in front bearing, use an arbor press and Tool J-6133 to install bearing while supporting the pinion shaft. Coat outer diameter of a new pinion seal with Permatex No. *2*, then start seal into carrier by tapping lightly and then finish driving in place with Tool J-5395. Apply a coating of seal lubricant, Part No. 567196 to companion flange and sealing lip of new seal. Support drive shaft and tap companion flange onto pinion shaft. Oil flat washer and threads of shaft and install washer and nut, but do not tighten.

Pini n Bearing Pr load - *CAUTION - Care must be taken in tightening companion flange nut to preload pinion bearings correctly. If specified preload has be n exceeded, it will b necessary to install a new spacer or a second wash r. DO NOT back off nut to secure proper preload.* With drive pinion properly installed in carrier (new compressible spacer, companion flange and nut installed), tighten companion flange nut using Flange Holding Tool J-6544, until all endplay in drive pinion assembly is removed. Continue to tighten carefully (not more than 1/6 turn at a time), and check bearing preload with an inch-pound torque wrench or a spring scale. Repeat tightening and checking until preload friction is correct, see table below.

Pinion Bearing Preload Setting

(1954-56)

New Bearings	24-32 inch lbs.
Old Bearings ①	15-20 inch lbs.

(1957-60)

New Bearings	24-32 inch lbs.
Old Bearings ①	10-12 inch lbs.

① - After several thousand miles usage.

►*COMPRESSIBLE PINION BEARING PRELOAD SPACER NOTE:* A second washer or a new compressible spacer and one washer must be used under the following conditions When a new ring gear and pinion is installed. When either front or rear pinion bearings are changed. When a new carrier is installed, or when the compressible spacer is compressed too much and the preload has been exceeded. If two washers are found between spacer and bearing assembly, one washer should be discarded and a new compressible spacer used.

Ring Gear Backlash & Differential Case Side Bearing Adjustment - *(NOTE* - When new parts, such as gear sets, bearings, etc., are installed, the markings on the carrier and adjusting nuts which indicated original position of gears and side bearing preloads, should be disregarded. Whenever original parts are installed the markings can be used to reset the adjustments providing original settings were correct). With differential case installed in carrier and adjusting nuts installed, install the bearing caps and capscrews (no washers) and draw them down sufficiently to lightly hold caps in place. Using Tool J-972-A back off the right hand adjusting nut (one opposite ring gear) approximately three turns. Tighten left hand adjusting nut to move ring gear into mesh with pinion until all lash is removed, **then back off adjusting nut three notches.** *(NOTE* - This is only a starting point and may need to be readjusted depending on backlash present after making the following adjustments).

Tighten the right hand adjusting nut while watching the outer race of bearing. When bearing race just starts to move along with adjusting nut, indicating tension on bearing, continue to tighten two notches. Tighten adjusting nut to align closest notch with capscrew hole in bearing cap. Tighten bearing cap bolts to 70-75 ft. lbs. Clamp dial indicator to differential carrier and check backlash between ring gear and pinion using Dial Indicator, Tool KMO-30. *(NOTE* - If same ring gear and pinion were installed, the backlash should be adjusted according to markings on bearing caps and adjusting nuts providing the differential was not disassembled to correct a noise complaint). If backlash is not within limits of .004-.006" (1954-56), .003" min. or .012" max. with .007-.008" preferred (1957-58), .005" min. or .009" max. with .007-.008" preferred (1959-60), loosen bearing cap bolts slightly, then move both adjusting nuts one notch at a time until correct backlash is obtained. To increase backlash, move ring gear away from pinion, and to decrease backlash, move it toward pinion. If left nut is backed off one notch, right nut should be tightened one notch. Tighten bearing cap bolts to 70-75 ft. lbs. (1954-58), 65-85 ft. lbs. (1959-60).

Pedestal Spread Measurement & Adjustment - Position Tool J-5340 (1954-56); J-511 (1957-58) over pedestal caps, then check clearance between gauge and machined surface of bearing caps. This clearance should be .004- 012" (1954-58). *NOTE - It is not necessary t check pedestal spread on 1959-60 models.* If clearance is less than specified, loosen right hand bearing cap bolts and loosen adjusting nut ½ notch and again tighten pedestal cap bolts and recheck clearance. *NOTE - Right hand nut should not be loosened mor than ½ notch from original 2 notch tight position.* If clearance is more than specified, then tighten right hand nut one notch After side bearing preload is correct, install bearing cap locks and lock bolts.

Carrier Installation: Clean gasket surface on housing and install a new gasket. Install carrier over studs and carefully align carrier with housing so that both pedestal caps enter supports in housing. Apply Permatex No. 2 on stud threads, then install nuts and tighten equally to draw carrier pedestal caps evenly into support in housing. Tighten nuts to 50-60 ft. lbs. Complete installation by reversing removal procedure.

1954-55 PACKARD HYPOID

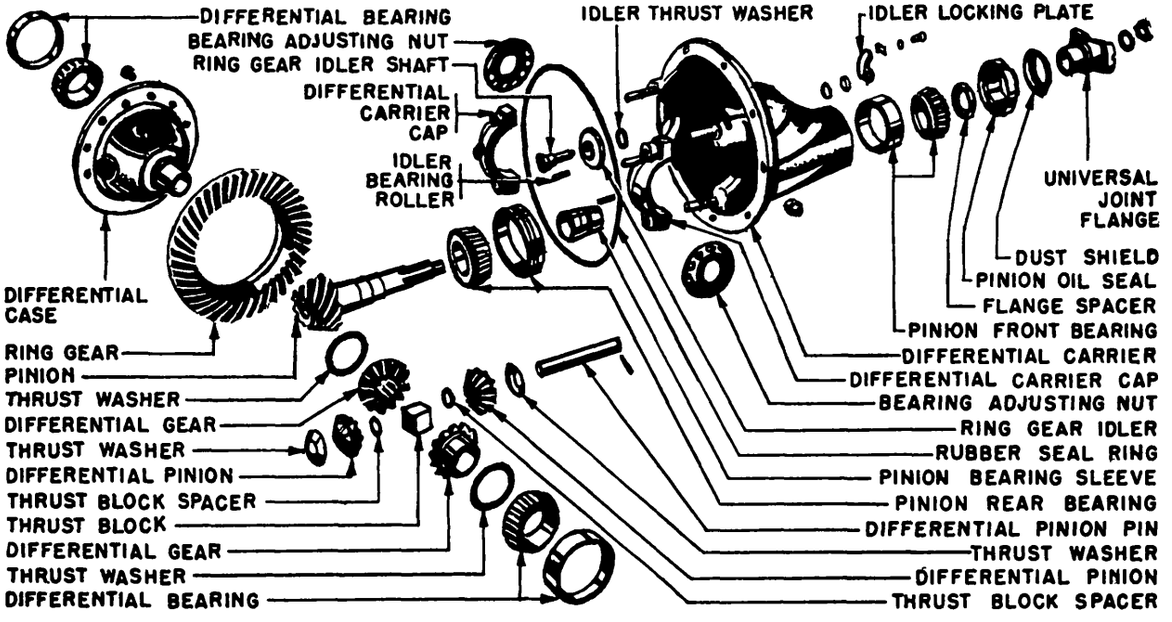
All Models (1954-55)

►***REAR AXLE ASSEMBLY NOTE:*** *Axle similar in design to previous types, but with heavier construction. Housing is heavier, bearings are larger, and axle shafts are larger.*

►***PINION BEARING PRE-LOAD CAUTION:*** *Adjustment procedure and settings changed. See OVERHAUL data below.*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss drive.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model page.*



AXLE SHAFT REPLACEMENT & ENDPLAY ADJUSTMENT: Raise car and place stand under each side of frame near rear spring front hanger. Remove rear wheel from hub and drum, then raise rear axle housing and place stands under housing near outer end. Remove hub and drum assembly using puller J-4153 *(CAUTION—Do not use "knock-off" type puller).* Disconnect hydraulic brake line from wheel cylinder. Remove brake support attaching nuts and lock washers. Remove seal guard, gasket, retainer, oil seal, brake support, and axle shaft bearing adjusting shims. Remove axle shaft and bearing using puller J-2552. *CAUTION*—Be careful that the axle shaft splines do not damage inner seal. To install axle, reverse the removal procedure. Adjust endplay by installing Tool J-2560, then with axle shaft forced in toward differential, turn long adjusting screw to bear aaginst backing plate, and then pull shaft outward. Check with feeler gauge to determine clearance which should be .004-.007". Add or remove shims at backing plate to obtain specified clearance.

OVERHAUL: Carrier can be removed from rear axle housing without removing axle assembly from car.

Carrier Removal: Remove axle shafts (see above), and disconnect propeller shaft at rear universal joint by removing screws and lock plates (On Ultramatic Drive cars, the universal joint is disconnected by removing bearings and cross from yoke). Prop propeller shaft up against floor with block of wood under it at "X" member. Drain lubricant from housing, and clean area around carrier gasket, then remove carrier and gasket from axle housing.

Carrier Disassembly: Securely clamp carrier flange in a soft jawed vise. Measure differential case run-out and replace if run-out exceeds .004". Mark carrier side bearing caps, bearing adjusting nuts, and pedestals with punch marks to insure correct installation. Remove carrier bearing capscrews. Hold ring gear and differential case in place with one hand and lightly tap bearing caps loose with hammer. Lift off differential case bearings, bearing cups, adjusting nuts and caps. (CAUTION—Bearing cap, bearing cup, and adjusting nut should be kept together until reassembly.)

Differential Disassembly: Remove ring gear attaching cap screws, tap the outside of ring gear with a soft hammer and loosen it. Remove ring gear from case. Drive out the differential pinion shaft lock pin, using a pin punch and hammer. Drive out pinion shaft. Remove differential pinions, pinion thrust washers, axle shaft thrust block, and spacers, differential side gears and thrust washers. Differential side bearings may be removed if necessary, using Tool J-3250, and adapter plate J-3250-4.

PACKARD HYPOID REAR AXLE

Pinion Shaft Removal: Remove universal joint flange nut using socket wrench J-5512, while holding flange from turning with Tool J-2659. Drive universal joint flange from shaft using a soft hammer. Drive out pinion, sleeve, and rear bearing using a soft hammer, then drive out pinion oil seal and front bearing in the same manner. Drive out front bearing cups from housing using Tool J-872-5, and Tools J-3235-A (front bearing cup), or J-5521 (rear bearing cup). Remove pinion rear bearing using Plate Holder J-2574 and Remover P-5508 in arbor press.

Pinion Shaft Installation: Install pinion bearing cups using Tool J-872-5 and Tools J-3230-A (rear cup), J-5506 (front cup). Press the pinion rear bearing onto pinion shaft until inner race is tight against shoulder. Install the pinion shaft collapsible spacer on shaft with large diameter of spacer toward rear bearing, then install assembly in carrier. Lubricate and install front bearing and tap into place on shaft. Lubricate pinion oil seal and install it in carrier using Tool J-3244. Coat splines of shaft with oil and install universal joint flange or yoke, dust shield, washer, and a new nut.

Pinion Bearing Preload Adjustment: (With carrier assembly out of car and with differential assembly removed)—Lock universal joint flange in vise and tighten flange nut with socket wrench J-5512 and a long handle wrench until only a slight amount of endplay can be felt in pinion shaft. *(NOTE—If a new collapsible sleeve is being used, a great amount of turning effort on the wrench will be required to buckle the sleeve).* Using a preload indicator wrench and adapter Tool J-2571-B and socket J-5512, notice the amount of torque required to rotate the pinion. **This indicates the amount of drag caused by pinion seal.** After seal drag torque is obtained, continue tightening the flange nut until pinion bearing preload is correct, the torque reading on the preload indicating wrench will read 2½ to 3 ft. lbs. PLUS the amount of torque that was required to overcome the oil seal drag (above). *(For example, if the oil seal drag was 2 ft. lbs., the reading on the indicating wrench should be 4½ to 5 ft. lbs.).*

Pinion Bearing Preload Adjustment: (With carrier and axle assembly in car)—Raise rear of car so that wheels are off floor. Be sure rear brakes are not dragging (it may be necessary to loosen rear wheel brake adjustments). Disconnect rear universal joint from pinion flange. Loosen the pinion flange nut (with Tool J-5512) and tap pinion shaft lightly to insure removing all preload on bearings. With preload indicating wrench and socket (J-5512), **measure the amount of torque required to turn pinion shaft, differential, and rear wheels** (rotate pinion shaft a few turns before taking torque reading). While holding universal joint flange with a large wrench, or applying the brakes, tighten pinion shaft nut until preload of 15 ft. lbs. is obtained, PLUS the amount of torque required to overcome drag of rear wheels, differential and pinion shaft (above). While pinion bearings are under the 15 ft. lbs. preload, strike the differential carrier a couple of sharp blows directly over front and rear bearing cups with a brass hammer. *(CAUTION*—Do not operate car at this high pinion bearing preload). Loosen pinion shaft nut until pinion shaft turns free, then retighten nut to obtain 2½ to 3 ft. lbs. torque on pinion bearings PLUS the amount required to overcome drag of rear wheels, differential and pinion shaft (above). Connect rear universal joint to pinion flange, and adjust the rear brakes.

Differential Reassembly: Install differential side bearings using Tool J-5507 and Handle J-872-5. Install differential side gear thrust washers on hubs of

CONTINUED ON NEXT PAGE

1954-55 PACKARD HYPOID (C ntinu d)

side gears, sticking them in place with cup grease. Install differential side gears and thrust washers in case. Coat cupped side of differential pinion thrust washers with grease and stick them to outer end of pinions, then place pinions in mesh with side gears, opposite each other, and rotate the side gears with the pinions until bore in pinions line up with pin bore in differential case. Start pinion pin into differential case so lockpin hole will line up with lockpin hole in case. As the pinion pin is pushed into case, install the thrust washer. Push pinion pin all the way in until lockpin hole registers with hole in case. (CAUTION—Measure the endplay of each side gear with feeler gauge placed between gear and thrust washer. If endplay not within .0015-.003" replace thrust washers with washers of correct thickness which are furnished in the following sizes: .031", .036", .041" & .046"). When correct endplay is obtained, and pinion pin installed, drive in the lockpin and stake edge of lockpin hole in case. Install ring gear on differential case and tighten capscrews evenly to 50-55 ft. lbs. Lubricate differential side bearings and place cups on bearings. Install differential assembly in carrier and install side bearing adjusting nuts and turn it in to make sure it is threading properly. Install bearing caps, lining them up with marks made at disassembly. Tighten capscrews enough to hold adjusting nuts in place and allow them to be turned. Temporarily adjust ring gear to pinion lash to approx. .010".

Differential Bearing Preload & Backlash Adjustment: Bearing preload is determined by measuring spread of carriers with a large outside caliper and a .010" feeler gauge. Back off side bearing adjusting nut on ring gear side one full turn so a little endplay can be felt in differential case. Place caliper and .010" feeler gauge against boss on pedestal cap and adjust caliper so jaw contacts pedestal boss on other side of differential case, to determine distance from outside of one pedestal to outside of other pedestal. Lock jaws of caliper in place so they will not be disturbed. Tighten the side bearing adjusting nut on ring gear side one full turn (previously backed off). Tighten adjusting nut opposite from ring gear side until caliper jaws will just contact both pedestal cap bosses **without** feeler gauge. (CAUTION—recheck pedestal spread).

Backlash Adjustment—Mount a dial indicator on carrier flange with indicator contact resting on face of ring gear tooth. Backlash should be .004-.008". By turning BOTH side bearing adjusting nuts in the same direction, ring gear can be moved toward or away from ring gear without disturbing side bearing preload. (NOTE—Moving both side bearing adjusting nuts in the same direction ONE NOTCH changes backlash .004"). Tighten side bearing cap bolts, recheck backlash.

Carrier Installation: Install new carrier sealing ring holding it in place with heavy grease. Install plastic seals on carrier studs and install carrier in axle housing. Tighten all carrier nuts to 35-40 ft. lbs.

PONTIAC HYPOID

All M d ls (1954-60)

►CHANGES, CAUTIONS, CORRECTIONS

►**PINION BEARING PRE-LOAD CAUTION: Pinion bearing pre-load must be adjusted** whenever universal joint companion flange nut on pinion shaft loosened (pre-load controlled by this nut and will be disturbed whenever nut loosened for any reason). See Pinion Bearing Pre-load data.

►**REPLACEMENT AXLE SHAFT CAUTION**—Axle shafts are covered with a protective coating of rust inhibiting grease. This grease must be completely removed before shaft installed in car (particularly between axle flange and oil guard flange) to prevent grease melting and running out on brakes.

►*1955 SPACER PRODUCTION CHANGE:* Early production differential have a two-piece spacer which fits over pinion stem and bears against inner races of pinion bearings. Late production differentials have a one-piece spacer which fits over pinion stem and bears against a shoulder on drive pinion and inner race of front bearing. **New spacer is not serviced. Ue new two-piece spacer for replacement of one-piece or two-piece spacer.**

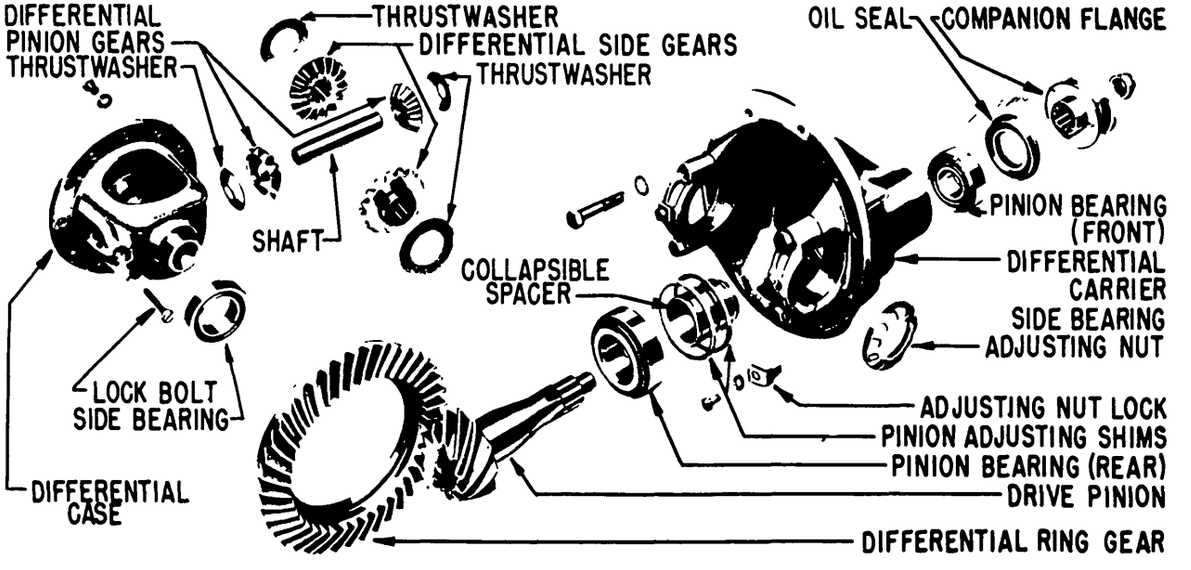
►*1956 PINION BEARING PRELOAD COMPRESSIBLE SPACER NOTE:* In production, a one-piece spacer is used for adjusting pinion bearing preload. A two-piece type spacer is furnished for service replacement, which replaces either a one-piece or a two-piece type.

DESCRIPTION: Semi-floating, hypoid gear type with Hotchkiss drive. Beginning with 1959 models, an oil gallery was included in housing to direct oil to front end of pinion shaft and the rear axle oil seals were pressed into end of axle shaft tube. In earlier models, the oil seal was combined with rear wheel bearing.

Differential Side Gears & Pinions - Gears are "crowned" teeth type to insure tooth bearing at center. Gears and pinions are interchangeable with previous type in c mpl te s ts only (individual gears and pinions must not be interchanged).

REAR AXLE RATIO & IDENTIFICATION: *See "Rear Axle" on Car Model pages.*

DIFFERENTIAL CARRIER ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model pages.*



AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Mod l pages.*

WHEEL BEARING & OIL SEAL REPLACEMENT: 1954-58 Models - With axle shaft removed, remove bearing inner retainer by carefully cutting it with a cold chisel. *CAUTION - Do not cut into shaft.* If a new bearing is to be installed, old bearing and retainer may be pressed off shaft together. With Tool J-947-P engaging outer race of bearing and ring enclosing bearing, press shaft out in an arbor press. *NOTE - If oil seal only is to b replaced, remove "0" ring from outer diameter of bearing race, then with an offset screwdriver, pry oil seal assembly from axle shaft bearing. Install "0" ring seal on bearing and start seal assembly into bearing, with lip side of seal toward bearing.* To reinstall bearing, install oil deflector, bearing outer retainer plate, and a new gasket. Install bearing on shaft using Tool J-947-P to bear only on bearing inner race and press bearing firmly against shoulder on shaft. Press a new bearing retainer ring in place firmly against bearing using Tool J-947-P. Reinstall axle shaft.

►*1954-58 BRAKE DRUM INSTALLATION CAUTION: Inner edge of brake drum must not extend beyond edg of backing plate. Install Gasket, Part No. 499930 between axle shaft flange and brake drum as necessary to correctly position brake drum.*

1959-60 Models - With axle shaft removed, remove oil seal from axle housing with Tool J-943. To remove

CONTINUED ON NEXT PAGE

P NTIAC REAR AXLE ASSEMBLY

PONTIAC HYPOID (C ntinu d)

bearing from shaft, install axle shaft in Tool J-947-P so tool engages outer race of bearing and ring enclosing bearing, then press bearing and retainer from shaft with an arbor press. To install bearing, install outer bearing retainer on shaft (if removed), then install bearing on shaft with Tool J-947-P (tool should bear only on inner race), pressing it into place with an arbor press. Press a new bearing inner retainer in place against bearing with Tool J-947-P. *CAUTION - Do not press bearing and inner retainer on in one operation as edge radius of retainer will climb over corner of bearing inner race and force grease seals into balls.* To install seal in housing, coat new seal lip with oil and coat outside of of seal retainer with Permatex No. 3 or similar compound, then install seal with Tool J-5818. Install axle shaft. *NOTE - If both axle shafts removed, shaft with left hand threads on wheel bolts must be on left side of car. Install bearing outer retainer and gasket and tighten self-locking retainer nuts to 30-45 ft. lbs.*

Pinion Shaft Oil Seal Replacement: Mark the position on companion flange, pinion nut, and pinion shaft to insure reassembly in the same location. *(NOTE* - If companion flange is to be replaced, it will not be necessary to mark the above parts as pinion bearing preload will have to be readjusted). Remove drive pinion nut and washer using Holding Tool J-6289, then remove companion flange with Puller J-6295. Remove oil seal by prying it out of carrier with a blunt tool. Oil lip of new seal and coat outer diameter with Permatex No. 3. Install seal by tapping into place with Tool J-5395. Install companion flange, then install washer and nut. Tighten nut until it and the companion flange are in the same position as marked at disassembly. *(NOTE* - Pinion nut will turn relatively easy until original position is approached and bearings begin to preload. Stop turning nut at this point and check position).

OVERHAUL: Carrier Removal - Remove axle shafts, then disconnect rear universal joint at the companion flange. Clean differential carrier adjacent to axle housing and drain oil by loosening all differential attaching bolts. Pull carrier out about 1/8" to allow oil to drain. Remove nuts and remove carrier assembly.

Carrier Disassembly: Mark right and left bearing caps and adjusting nuts, then remove adjusting nut locks. Loosen bearing cap bolts and back off on left adjusting nut to relieve side bearing preload. Remove bearing caps and adjusting nuts, then remove differential case assembly from carrier. *(CAUTION* - Keep outer bearing races with side bearings so these mating parts can be reassembled in the same location). Remove drive pinion nut and washer using a heavy duty socket and Holding Tool J-6289, then remove companion flange with Puller J-6295 and Holding Tool J-6289. Remove pinion from carrier, being careful not to damage threads or oil seal. If pinion does not slide freely from front bearing, temporarily install pinion nut and lightly tap pinion out of bearing with a soft hammer. If necessary, use an arbor press to press pinion through bearing. Remove spacer and spacer washer (if washer installed). Remove pinion oil seal with a screwdriver. On 1954-56 models, press front and rear bearing cups out of carrier with Remover J-2938 and Handle J-2940 (Front), J-2936 and Handle J-2940 (Rear). On 1957-60 models, press front bearing cup out with Tool J-6198 and Handle J-8092, and rear bearing cup out with Tool J-6533 and Handle J-8092. On 1954-56 models, use Holder J-358-1 and Plates J-2934 to remove rear bearing. On 1957-60 models, use Tools J-6555 and J-7407 to remove rear bearing. Remove pinion setting shims (from carrier 1954-56 from pinion shaft 1957-60).

Differential Case Disassembly: Remove pinion shaft lockscrew and washer and drive pinion shaft out of case. Remove pinions, side gears and thrust washers. If necessary, remove ring gear from case. If side bearings are to be replaced, install Remover Tool J-986-P with hooks of puller in recesses in differential case and pull bearings off.

Differential Case Reassembly: Position ring gear on case. *(CAUTION* - Do not use hammer to force ring gear onto case). Install ring gear attaching bolts and tighten all bolts evenly to 55-60 ft. lbs. *(NOTE* - Tighten screws finger tight first, then tighten evenly and alternately across diameter in progressive steps until final tightness is reached). Install side bearing on hub of differential case using Tool J-5292. After bearing has been installed on one side, support side bearing with a front wheel bearing outer race or other suitable means, then install opposite side bearing. Lubricate gears and thrust washers, then place side gear thrust washers over hubs and install side gears in case. While holding upper side gear up into its bore, position one pinion gear (without thrust washer) between side gears and rotate gears until pinion gear is directly opposite loading hole in case. Place other pinion in position between side gears so that pinion shaft holes line up. Rotate pinion gears in position to assure pinion gear shaft holes in gear are lined up with shaft holes in case. If holes are not lined up, pinion will require positioning in side gear teeth. With gears properly meshed, rotate assembly just enough to permit working the pinion gear thrust washers into position between gears and case. Install gear shaft and lock it in place with lockscrew and washer.

Carrier Reassembly: Reverse disassembly procedure and note the following:

Pinion Gear Setting - Before assembling the carrier, the correct number of shims required to locate drive pinion properly must be determined from markings on differential carrier and on end of pinion. Carrier is marked on face of flange with either of the following codes: "D" (indicating "deep"); "S" (indicating "shallow"); "O" (indicating "standard"). The digit following the letter designates number of thousandths "deep"

CONTINUED ON NEXT PAGE

PONTIAC HYPOID (C ntinu d)

or "shallow". *NOTE - A carri r marked "0" will requir .010" (1954-56), .016" (1957-60) of shims in housing or under pinion bearing, plus or minus the markings on pinion.* Pinions are marked (+) or (-) together with the number indicating in thousandths of an inch the shims required to position pinion in carrier. *NOTE - Drive pinions machined to zero specifications ar not marked.* Determine markings on carrier and on pinion, then refer to "Pinion Shim Chart" for correct thickness of shims to use.

►*PINION SHIM NOTE:* **Pinion shims are furnished in the following sizes and are marked for identification as follows:**

1954-56 Shims - .002" (Plain), .003" (Blue or Plain Color or 1 hole), .004" (Copper or Plain Color or 2 holes), .005" (Plain), .010" (Plain).

1957-60 Shims - .004" (Plain), .005" (Blue), .006" (Copper), .007" (Plain), .010" (Plain).

Pinion Driv Gear Installation - 1954-56 Models - Use Holder J-358-1 and Plates J-2934 to install new rear bearing on pinion shaft (bearing must seat solidly against shoulder on shaft). Install correct pinion adjusting shim pack (see Pinion Setting data above) against shoulder of rear bearing bore in carrier, press bearing cup in place with J-2937 Installer and Handle J-2940, then install front bearing cup using J-2939 Installer and Handle J-2940.

1957-60 Mod ls - Press rear bearing race into carrier with Tool J-6255 and J-8092. Install front bearing race with Tool J-6197. Install correct number of shims against shoulder of drive pinion shaft (see Pinion Setting above), then lubricate rear bearing and press it onto shaft with Tool J-6547 and Plate J-6407.

On All M d ls - Place a new compressible spacer over pinion and install the assembly in carrier housing. Oil pinion front bearing and roller assembly and install on pinion shaft. Coat outer surface of seal retainer with Permatex No. 3 or similar compound, then install seal by tapping it into place using Tool J-5395-A. Install companion flange, then oil threads of pinion nut and face of washer and install these parts. Position entire assembly horizontally and tighten pinion nut only enough to remove endplay, using Flange Holding Tool J-2933 (1954-56), J-6289 (1957-60) and a heavy socket.

Pini n B aring Pr load - *(CAUTION - Extr m car must be taken when tightening pinion nut to preload bearings correctly. Never back off nut to reduce preload. If torque required to keep pinion turning exceeds the following specifications, a new bearing spacer must be installed).* With drive pinion properly installed in carrier (companion flange, nut, and a new compressible spacer installed), tighten pinion shaft nut using Flange Holding Tool J-6289 and a heavy socket until all pinion shaft endplay is removed. Continue to tighten the nut a little at a time, stopping frequently to turn pinion several revolutions to seat rollers and to check turning torque with an inch-pound torque wrench (Tool KMO-652). Repeat this procedure until turning effort required to keep pinion moving is as follows:

Pinion Bearing Preload Setting

(1954-56)

Pinion Bearings	Bearing Preload
New Bearings	27-37 inch lbs.
Old Bearings ℂ	ℂ 10-12 inch lbs.

(1957-60)

New Bearings (New Seal)	24-32 inch lbs.
New Bearings (Old Seal)	22-26 inch lbs.
Old Bearings (New Seal)	12-15 inch lbs.
Old Bearings (Old Seal) ℂ	10-12 inch lbs.

ℂ - After several thousand miles usage.
ℂ - Supersedes original specifications of 15-20 inch lbs.

►*NOTE:* Torque measurement may be taken using a spring scale hooked to Holding Tool J-6289 at a point 10" from pinion shaft center. Reading in lbs., times 10 will give the inch-pounds.

Ring Gear Backlash & Differential Side Bearing Adjustment - Hold outer races squarely on side bearings and install differential case into carrier, positioning ring gear against pinion gear. Place adjusting nuts (on correct sides as indicated by marks) into threads of pedestals and squarely against outer races. Install bearing caps and capscrews making certain that threads in caps match those in adjusting nuts. Tighten capscrews slightly more than finger tight. Tighten right adjusting nut, backing off left nut, if necessary, to bring adjusting nuts into full contact with outer races and to provide a slight amount of backlash. When turning nuts keep them in contact with races to maintain a slight amount of preload on bearings. Tighten left nut, backing off right nut, if necessary (keeping nuts against bearing), while rocking case until backlash has just been eliminated. If left nut is not in a locking position when backlash has been eliminated, back off to nearest locking position. Back off right nut to insure that nut and outer race do not turn together. Retighten right nut until outer race just starts to turn with nut, then mark this point on adjusting nut. Tighten right nut **one notch**, tap each bearing cap, and rock ring gear. Check backlash as follows: Install Dial Indicator, KMO-30 on carrier flange so indicator button is bearing against rear face of a ring gear tooth, then measure the movement of ring gear against pinion. Continue to turn right nut until it has been tightened a total of two to three notches. Recheck backlash which should be .003-.012". Tighten bearing cap bolts to 70-75 ft. lbs. tapping each bearing cap several times with hammer while tightening to insure proper seating of caps.

Carrier Installation: Clean interior of axle housing with solvent and thoroughly clean surface of housing contacting carrier gasket. Install a new gasket, then install carrier over bolts in housing. Tighten attaching nuts to 45-60 ft. lbs. Install axle shafts (see above), then connect rear universal joint to companion flange. Tighten nuts to 14-20 ft. lbs., then bend ears of lockplate up against flat side of nuts.

Carrier Oil Gallery Plug Replacement (1959-60 Models): *NOTE - This plug is located at forward end of differential carrier housing lower reinforcing web.* **Mark position of companion flange, pinion nut and pinion shaft so all parts may be installed in exactly the same positions to maintain proper pinion bearing preload. Remove companion flange and pinion shaft, then thread a ½" bottom tap into plug until plug starts to turn. Remove plug by turning tap and pulling at the same time. To install plug, apply a light coat of Permatex No. 3 to hole in carrier and to plug, then install plug, making sure that it does not enter drain hole.** *CAUTION - Do not attempt to drill a hole in plug for removal as shavings will fall into drain hole.*

1958-60 RAMBLER HYPOID

Rambl r American (1958-60)
Rambler 6 Cyl. & V8 (1958-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*REAR AXLE DRAIN & REFILL NOTE:* Drain and refill periods are no longer recommended and drain plug is being discontinued in production.

►*1958 SERIES 20 REAR AXLE NOTE:* Spicer type rear axle assemblies used on this series with Flash-O-Matic Transmission from beginning of production to Serial No. A-17647 and from Serial No. A-17701 to A-18257. *See "Spic r Hyp id" in this s cti n.*

►*REPLACEMENT HUB AND AXLE NOTE:* New hubs are not serrated. Serrations are cut when hub and shaft are assembled. DO NOT install an old hub on a new shaft as serrations in old hub will not match serrations in new axle, however a new hub may be installed on old shaft but scribe hub and shaft for reinstallation. *NOTE* - When installing new hub, tighten axle shaft nut until distance from outside face of hub to outside taper on axle shaft is 3/16" (regardless of torque required).

►*REAR BRAKE DRUM INSTALLATION CAUTION:* When tightening axle shaft nut for either new wheel hub installation or replacement of old hub on old axle (250 lbs. torque) or when adjusting axle shaft endplay, results in brake drum contacting support plate, install 1/16" spacer Part No. 3200966 between hub and drum. Spacer must be installed with three small screws used to hold drum to hub

►*1959 6 CYL. MODEL PINION SETTING ADJUSTMENT NOTE: Two types of drive pinions are used in production, each of which requires a different adjustm nt procedure. See "Pinion Gear Installation & Adjustment" below.*

►*1960 6 CYL. REAR AXLE ASSEMBLY PRODUCTION & OVERHAUL PROCEDURE CHANGE:* Three types of axle assemblies are used as indicated below:

First Type - Same as 1959 Models.

Second Type - Pinion bearings and side bearings have been changed dimensionally. This type axle assembly can be identified by the side bearing cup number (Timken No. LM-501311). Service procedures for this

CONTINUED ON NEXT PAGE

1958-60 RAMBLER HYPOID (C nt.)

type axle are the same as for previous models except that certain new tools are required (s "Ov rhaul" below).

Third Type - Same as second type except that inner end of axle shaft has 27 "rolled" splines in place of the 16 machine cut splines.

►*1960 V8 REAR AXLE PRODUCTION CHANGE:* Two types have been used as follows:

First Type - Same as 1959 models. Axle shaft has 16 machine cut splines on inner end.

Second Type - Same as first type except that inner end of axle shaft has 29 "rolled" splines in place of the 16 machine cut splines.

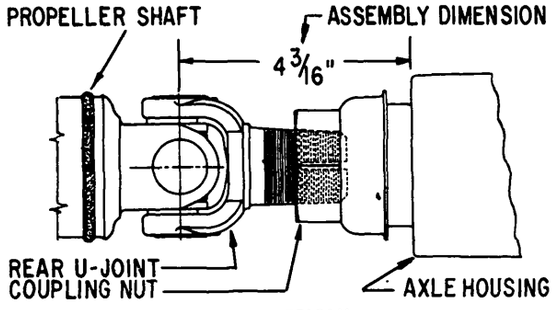
►*1960 6 CYL. (EARLY AUTOMATIC TRANSMISSION CARS) DIFFERENTIAL SIDE GEAR BREAKAGE CORRECTION:* This condition is caused by automatic transmission front clutch. *See "Rambler Six Transmission Front Clutch Production Change & Service Replacement Note" under "Rambler & Checker Superba Automatic Transmission".*

DESCRIPTION: Own. Semi-floating, with hypoid type ring gear and pinion, Hotchkiss drive (Rambler American), torque tube drive (others).

AXLE SHAFT REPLACEMENT: Remove wheels and drums. Pull hubs with Puller J-1644-B or J-736-B, then check axle shaft endplay (.002-.004") with Tool J-2092. Remove brake support plate, oil seal retainer, seal and shims. *NOTE* - Seal is located in retainer between axle tube and brake support plate (6 Cyl.), behind dust shield (V8). Use Puller J-2498-B to remove axle shaft. Remove bearing cup and remove bearing cone with arbor press. To install, use new seal soaked in light lubricating oil and reverse removal procedures.

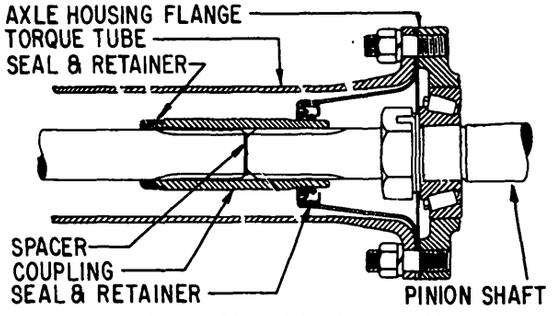
WHEEL HUB INSTALLATION: 1) Slide hub onto axle shaft aligning punch marks on shaft and hub, then place two lubriplated thrust washers between nut and hub (to facilitate installation) and tighten axle nut to 250 ft. lbs. torque. *NOTE* - When installing a new hub on new or old axle shaft, tighten nut until outer face is 3/16" from outer end of taper on axle shaft, then punch mark both hub and axle shaft. Remove lubriplated thrust washers and reinstall axle nut and tighten to above specifications.

►*AXLE SHAFT BEARING INSTALLATION NOTE:* Pack axle shaft bearings with a good grade of wheel bearing lubricant and install bearing with Tool J-2995.



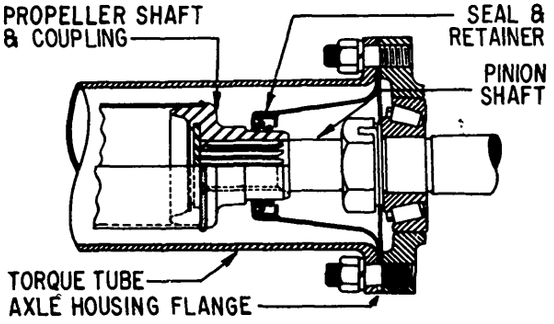
REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" n Car Model Pages.*

"POWER-LOCK DIFFERENTIAL" DISASSEMBLY: *See "Power-Lock Differential".*



PROPELLER SHAFT REMOVAL (SERIES 10, 20, 80): Disconnect truss rods, torque tube and propeller shaft from rear axle. *NOTE - Do not lose spacer (Synchro-mesh & Overdrive).*

PROPELLER SHAFT CENTER BEARING REMOVAL (Synchro-mesh & Overdrive): Remove snap ring and press propeller shaft through center bearing.



TORQUE TUBE & TRUNNION BRACKET ADJUSTMENT (SERIES 10): With rear end of propeller shaft against pinion shaft and torque tube attached to rear axle

5801 AMERICAN

5810, 20, 80 STD. & O.D. TRANS. CARS

5810, 20, 80 AUTO. TRANS. CARS
PROPELLER SHAFT COUPLINGS

housing, front end of propeller shaft should protrude 1/8-1/4" beyond front face of trunnion bracket. Adjustable clamp screw should be tightened enough to remove excess clearance without setting up friction.

►*REAR AXLE TRACK BAR (STABILIZER) CAUTION:* The connection at rear axle and body bracket must be kept tight to maintain vertical alignment between rear axle and body. If loose, it will cause noise and body sway.

OVERHAUL

►*1960 6 CYL. MODEL "SECOND" & "THIRD" TYPE REAR AXLE OVERHAUL NOTE:* Because of a change in bearing sizes used with these axles, the following new tools will be required: Tool No. J-7828 (Rear Pinion Bearing Remover); J-7817 (Front Pinion Bearing Cup Installer); J-7818 (Rear Pinion Bearing Cup Installer); J-6318-2 (Pinion Setting Gauge Discs). *NOTE - Small diam t r discs are us d for "second" & "third" typ s. Larg diam ter discs are used for prior type.*

►*1960 6 CYL. MODEL DIFFERENTIAL SIDE BEARING & PINION BEARING PRELOAD SHIM NOTE (MODELS WITH "SECOND" & "THIRD" TYPE AXLE ASSEMBLIES):* On cars with these type axle assemblies, use Differential Side Bearing Shims, Part Nos. 3202326 (.142") to Part No. 3202343 (.176") in .002" variables. Pinion Bearing Preload Shims, Part Nos. 3202285 (.170"); 3202286 (.002"); 3202287 (.003"); 3202288 (.005"); 3202289 (.010"); 3202290 (complete set).

DIFFERENTIAL REMOVAL: Remove cover bolts, cover and gaskets (save Ratio Tag attached to one bolt). Use center punch to mark bearing caps for reinstallation. Insert two bars through differential case and pry differential assembly out of housing. DO NOT damage bearing cups, rollers or shims. *NOTE* - Tie side bearing shims to respective side bearing and cap for reinstallation.

DISASSEMBLY: 1) Use Puller J-2497 to remove side bearing cones (do not pull on rollers). Remove ring gear capscrews and tap ring gear from case. *CAUTION* - Do not chisel or wedge ring gear from case. Use 3" long drift to drive out differential pinion shaft lock pin. Drive out pinion shaft and drop out thrust block through side gear. Roll differential pinion gears and remove them and side gears from case and lift out thrust washers.

2) Remove pinion oil seal, locknut and tap end of pinion shaft lightly to free front bearing cone from pinion shaft and remove bearing. *NOTE* - Shims are located between bearing and shoulder on pinion shaft and should be retained for reassembly as they control endplay. Remove pinion gear and rear bearing from rear of housing. Use Remover J-2244 (s "1960 6 Cyl. Mod l Second & Third Type Rear Axl Ov rhaul Not " abov for special tools required for thes axl s) and an arbor press to remove pinion rear bearing. Remove pinion bearing adjusting washer and mark for reinstallation.

INSPECTION: Clean all parts in cleaning solution and inspect as follows: Differential pinion shaft for wear. It should be a press fit in case to .010" loose fit. Thrust block should be free of wear or distortion. Check pinion gears for excessive wear or chipping and check with pinion shaft for wear in hole. Always use new thrust washers. Differential side gears should be free of wear, cracked or chipped teeth and be a snug fit on splined shaft. Side gear to case clearance should not exceed .007" and endplay when assembled should be 0" to .008" with .004" desired. Not to exceed 8 ft. lbs. should be required to rotate internal gears. Dress down differential case bearing surfaces with stone or file. Check ring gear for cracks or chipping and examine tooth contact pattern. Replace both ring gear and pinion when tooth pattern indicates gears have not been meshing properly. Replace ring gear-to-case capscrews

CONTINUED ON NEXT PAGE

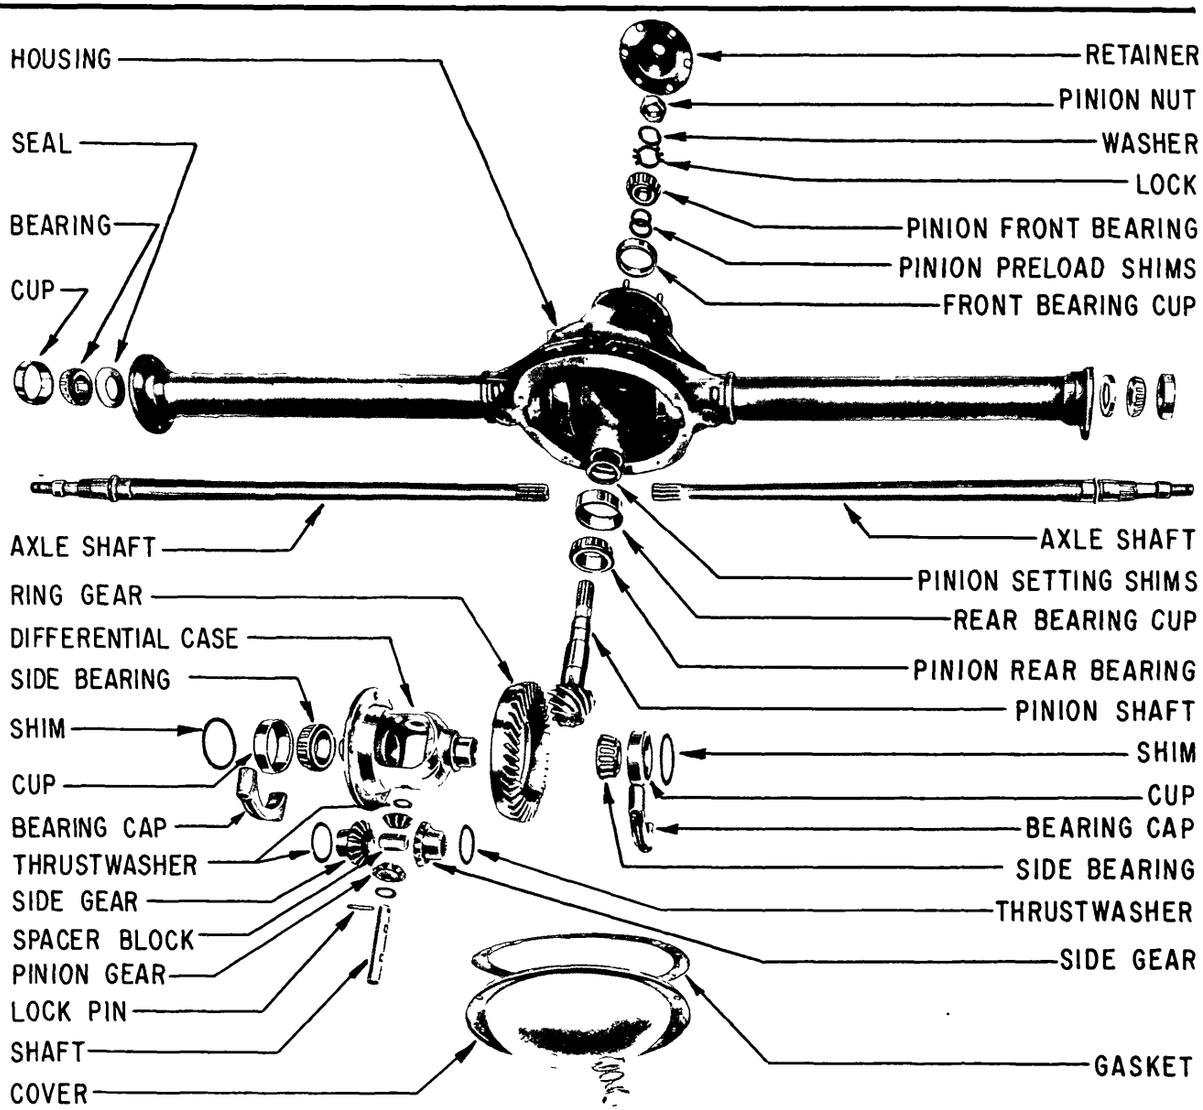
1958-60 RAMBLER HYPOID (C nt.)

if elongated. First etched mark on rear face of pinion gear should match etched mark on edge of ring gear. The second number with either a + or - sign indicates corrected pinion cone setting. An "O" indicates no correction necessary. Oil seal surface should be free of wear or roughness and pinion splines should not be damaged. Replace both cone and bearing if worn, or show over-heating or scoring. Inspect housing for cracks, sand holes or burrs, deep scratches or nicks on gasket or oil seal areas. Bearing cup bores should be free of burrs or nicks. Clean axle tubes.

REASSEMBLY: *NOTE* - Specifications for adjustments are on the basis of dry parts. Use new thrust washers and oil seals.

Differential Cas - 1) Place thrust washers on side gears with oil pocket side toward gear and install gears in case bores. Place thrust washers behind differential pinion gears and mesh them with side gears, then roll pinion gears around to align them for installation of pinion gear shaft. Place pinion gear shaft into case, add thrust block and align pin hole with hole in case. Check clearance of side gears. Drive lock pin in place.

2) Press differential side bearings on case with Replacer J-2100 or J-5364 (6 Cyl.); J-2104 or J-2646 (V8). Place cup over side bearing and insert differential in case, adding one .075" thick shim on each side between bearing cup and housing. *NOTE - See "1960 6 Cyl. Mod l Diff rential Side Bearing & Pinion Bearing Pr load Shim Not "* above. Eliminate sideplay by installing correct thickness side shim (single shim should be used at each side). *NOTE - If an additional thickn ss of shims is required to eliminate sideplay n V8 mod ls, adjusting shims may be installed betw n b aring con and differential case. Thin shims, .003", .005", .010" ar available.* When all side play is eliminated, a slight drag should be present.



3) Install correct bearing caps and tighten to 55-60 ft. lbs. (6 Cyl.); 105-110 ft. lbs. (V8).

4) Check ring gear case runout (.002" maximum) with dial indicator. Remove differential case from housing retaining shims used for endplay elimination.

5) Use two 3/8"-24 x 1" capscrews to guide ring gear on case and tighten capscrews to 45-50 ft. lbs.

PINION GEAR INSTALLATION AND ADJUSTMENT: Correct shim pack to go between rear bearing cup and pinion gear is determined by the marking etched on rear face of pinion. Example - If original shim pack was .035" thick with pinion marked +2 and new pinion to be installed is marked -1, shim pack must be increased .003", represented by difference between +2 and -1.

►*1959 6 CYL. MODEL REAR AXLE PINION DEPTH SETTING (PINIONS NOT HAVING MACHINED END FACE):* Pinion depth setting on pinions without a machined end face is done WITHOUT pinion gear and shaft installed in housing. *See "Pinion Setting Adjustm nt".(6 Cyl. Models Without Machined Face on Pinion). NOTE - On mod ls with this type pinion, pinion depth setting shims are installed betwe n pinion g ar and bearing cone (between bearing cup and housing on other models).*

1958-60 RAMBLER HYPOID

►*1960 6 CYL. MODEL "SECOND" & " THIRD" TYPE REAR AXLE OVERHAUL NOTE: Because of change in bearing sizes used with these axles, use the following tools in place of those indicated below: Front Pinion Bearing Cup Installer, J-7817; Rear Pinion Bearing Cup Installer, J-7818; Pinion Setting Gauge Discs, J-6318-2.*

►*1960 6 CYL. MODEL PINION BEARING PRELOAD SHIM NOTE (MODELS WITH "SECOND" & "THIRD" TYPE AXLE ASSEMBLIES):* Use Pinion Bearing Preload Shims, Part Nos. 3202285 (.170"); 3202286 (.002"); 3202287 (.003"); 3202288 (.005"); 3202289 (.010"); 3202290 (Complete Set).

1) Use Tool J-2995 (6 Cyl.) or 1 11/16" x 8" steel pipe (V8 Models) to press or drive rear bearing cone (large diameter toward gear) against pinion gear. Use Tool J-2534 or J-5367 (6 Cyl.) or J-2533 (V8 Models) to replace rear bearing cup in housing, placing predetermined shims between cup and housing. *CAUTION - Drive the bearing cups straight into clean bores.*

2) Use Tool J-2532 (6 Cyl.) or J-2531 (V8 Models) to install front pinion bearing cup in housing. Insert drive pinion in housing and install original pinion bearing preload shim pack on pinion shaft shoulder.

CONTINUED ON NEXT PAGE

1958-60 RAMBLER HYPOID (C nt.)

NOTE - For v ry shim add d to or d ducted from pinion d pth adjustm nt shim pack, d duct or add a like amount to pinion bearing preload shim pack for preliminary preload setting.

3) Install front bearing cone and rollers on pinion shaft. Install washer, lock ring and nut (do not bend lock ring on nut). Torque pinion nut to 90-100 ft. lbs. (6 Cyl.); 125-150 ft. lbs. (V8 Models).

4) Mount disc J-2499-2 on Gauge Arbor J-6482-1, or disc J-5223-17 on Gauge Arbor J-5223-4 (6 Cyl.). Use large diameter discs J-2499-2 and Arbor J-6482-1, or discs J-5223-5 on Gauge Arbor J-5223-4 (V8 Models). Position Gauge Block J-5223-20 against end of drive pinion with clamp bar and screw J-5223-6 and J-5223-14. Loosen thumb screw in end of gauge block to permit spring loaded plunger to contact gauge arbor. Lock plunger with setscrew. DO NOT disturb plunger position.

5) Remove gauge block and measure distance from end of anvil to top of plunger head with a 2-3" micrometer. This distance should be 2.095" (6 Cyl.), 2.457" (V8 Models), with "O" marked pinions. Add or deduct pinion adjusting shims (located between bearing cup and housing) to correct this reading on "plus" or "minus" marked pinions.

Pinion Setting Adjustment (6 Cyl. Models Without Machined Face on Pinion): *NOTE - Use Gauge J-2499 for pinion depth adjustment.* Place rear pinion bearing cone in bearing cup and rotate it a few times to "set" the rollers, then bolt gauge plate over bearing cone so that it does not touch housing at any point (bolt runs down through housing and is secured at pinion end). Attach a dial indicator to tool. With indicator button on top of gauge pin, set dial indicator (under tension) to zero. Install tool with adapter discs seated squarely in side bearing bores in housing. *NOTE - Use small diameter discs of adapter.* Swing gauge point across plate until highest reading is obtained. This reading subtracted from a constant of .140" will give standard shim thickness for that particular housing. Using this figure, add or subtract, according to marks on end of pinion, to obtain correct adjusting shim thickness. For example: When gauge point is moved across plate and a reading of .015" is obtained, subtracting this figure from the constant of .140" will give a standard of .125". This means that if a standard "O" pinion is being used, adjusting shims totalling .125" would be required. However, if marking on pinion is -3 (meaning that pinion is an additional .003" away from ring gear), it would be necessary to add this .003" to standard. Thus, the adjusting shim pack thickness would be .128".

PINION BEARING PRELOAD ADJUSTMENT: *NOTE -* Thickness range from .106" to .138" can be obtained by using two of the following size shims: .053", .054", .056", .058", .059", .063", .064", .066", .068" or .069".

1) Use a piece of flat bar 3/8" thick, approximately 13" long by 2" wide welded to a slip-type coupling. Drill two holes 6" from exact center of coupling to accept the spring scale claws. Cut a ½" square hole 12" from exact center of coupling to make tool for extension when torquing pinion nut.

2) To check pinion bearing preload attach spring scale to center of handle, pull tool in circular motion and note reading in lbs. on scale, then multiply by 6. This determines the inch pounds necessary to turn shaft. *NOTE* - Turn axle up to eliminate effect of gravity and pull horizontally.

►*NOTE: See "1960 6 Cyl. Model Pinion Bearing Preload Shim Note (Models with "Second" & "Third" Type Assemblies)" above.*

3) Pinion bearing preload should be 12-14 inch pounds (6 Cyl.), or 15-18 inch pounds (V8 Models). Increase shim pack to reduce preload or decrease shim pack to increase preload.

RING GEAR & PINION BACKLASH ADJUSTMENT: 1) Install differential assembly in housing and tighten bearing caps to 55-60 ft. lbs. (6 Cyl.); 105-110 ft. (V8 Models). Attach dial indicator to housing with button contacting drive side of a tooth on ring gear and note movement of gear on dial indicator. Backlash should be .002-.006" with .004" desired.

2) To increase backlash, install a thinner shim on ring gear side and a thicker shim on opposite side. *CAUTION - Do not chang total shim pack thickn ss. S "1960 Mod l Diff r ntial Sid B aring & Pinion Preload Shim Note (Models with "S c nd" & "Third" Typ Axle Assemblies).*

DIFFERENTIAL SIDE BEARING PRELOAD ADJUSTMENT: Correct preload is .004-.008". Add .004-.008", shims (between shim packs) when all side play has been eliminated.

DIFFERENTIAL ASSEMBLY INSTALLATION: 1) Assemble side bearing cups and shims on side bearings. Lower assembly into axle housing until bottom edge of bearing cups and shims are started in bearing bore (keep differential assembly square in housing and push it down as far as possible). Use a soft hammer to tap outer edge of bearing cups until seated in housing. *CAUTION - DO NOT DISTURB SHIMS.* Install bearing caps and torque to 55-60 ft. lbs. (6 Cyl.); 105-110 ft. lbs. (V8 Models). *NOTE - R check backlash and c rrect as necessary.*

PROPELLER SHAFT INSTALLATION (Rambler American): Install propeller shaft and coupling on pinion shaft until center of universal joint yoke is 4 3/16" from front face of rear axle housing, then tighten coupling (use Wrenches J-4486) to 300 ft. lbs.

PROPELLER SHAFT INSTALLATION (EXCEPT RAMBLER AMERICAN): Synchro-m sh & Overdriv Trans. - Install propeller shaft oil seal and retainer on propeller shaft. Place forward end of propeller shaft against wood block and drive coupling (use a lead hammer) on propeller shaft to shoulder on splined area in coupling. Tap retainer and oil seal on coupling, then install spacer and torque tube rear oil seal. Lubricate ground surface of coupling and torque tube rear oil seal with rear axle lubricant and install propeller shaft and coupling on pinion shaft. *NOTE - Do not crimp lip of seal as it must contact ground surface of coupling.*

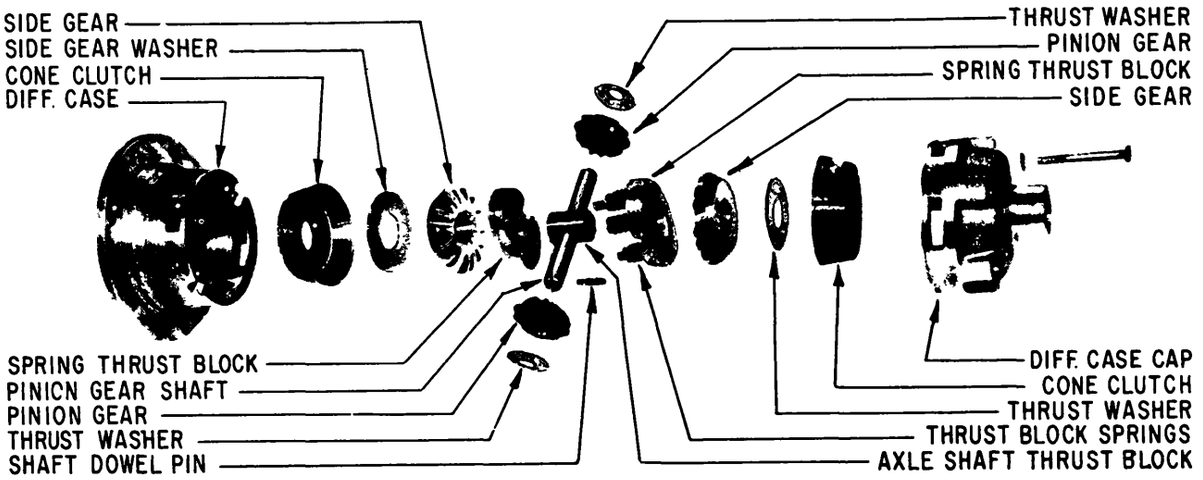
Automatic Trans: Coupling is part of propeller shaft. *NOTE - Do not crimp seal when sliding coupling on pinion shaft as it must contact ground surface of coupling.*

RAMBLER TWIN-GRIP DIFFERENTIAL

Rambler 6 Cyl. (1959-60)

►*NOTE: For Rambler V8, See "Power-Lock (Plate Clutch Type)".*

DESCRIPTION: This unit is a "limited slip" (or locking) type differential assembly which directs the major driving force to the rear wheel with the greater amount of traction. The limited slip action is accomplished by two spring loaded thrusts blocks which bear against each side gear, which in turn are seated in a tapered cone clutch member inside each differential case half. The thrust block spring load is calibrated to permit slippage under variable torque conditions (turning corners or other unbalanced tractive conditions), allowing the torque created on one wheel by differential action to overcome thrust block spring load on side gears.



REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model Page and not the following:* DO NOT rotate one axle shaft until both shafts are in position. Rotation of one shaft without the other shaft installed will result in misalignment of cone and side gear splines and prevent entry of second shaft.

DIFFERENTIAL ASSEMBLY REMOVAL & INSTALLATION: *See "Rambler Hypoid" Rear Axle.*

To prevent unnecessary disassembly of rear axle and differential, proper operation and effectiveness of the differential unit can be determined as follows: With transmission in neutral and engine turned off, raise one rear wheel on a jack. Turn raised wheel in a forward motion with a socket and torque wrench on axle shaft nut. A torque reading of 80—120 ft. lbs. should be attained before differential assembly will slip. If the torque reading is within the above range, differential assembly is in proper operating condition.

►*TWIN-GRIP DIFFERENTIAL ASSEMBLY OVERHAUL*

NOTE: Individual components of the differential assembly are not available for service replacement. If necessary to replace parts, the complete unit assembly must be replaced. The following outlined procedures are for inspection and cleaning.

RAMBLER TWIN-GRIP DIFFERENTIAL ASSEMBLY

DISASSEMBLY: Remove differential case cap retaining bolts and separate the two halves of differential case. Remove all parts and wash in solvent, then dry with air.

INSPECTION: Inspect all parts for wear or damage. Inspect cone seats in differential case and male cone surfaces for excessive wear. Cone surfaces in case should be slightly grooved and male surfaces of cones should be grooved similar to transmission synchronizer friction rings. If excessive wear or damage is found, replace complete unit.

REASSEMBLY: Clamp an axle shaft in a vise vertically, allowing about 3" of splined end to extend above jaws. Place ring gear flange side of differential case over shaft with interior of case upward, then install the cone having the word "flange" stamped on it into case, over the axle shaft splines. Place washer and side gear over axle shaft and seat side gear on cone mounting face. Position one of the spring thrust blocks over gear face in alignment with pinion gear shaft grooves. Install pinion shaft, axle shaft thrust block, pinion gears, and thrust washers into flange half of differential case, positioning the assembly so pinion shaft dowel can be inserted through pinion gear shaft and into differential case. Insert springs into spring pockets (6 large springs and 2 small springs), then install the two small springs inside the two large springs located at each end of spring thrust block. Install second thrust block over spring and thrust block assembly. Align second side gear to mesh with pinion gears and Install it face down on spring thrust block, then place side gear washer and the remaining cone, stamped "cap", over side gear. Install differential case cap over cone in proper position, then insert two bolts 180° apart and tighten finger tight. Install the other axle shaft through cap side of differential case, turning it to enter splines in cone and side gear. Leave axle shaft in this position, then insert remaining bolts and tighten to 15—18 ft. lbs. Remove axle shafts, tapping with a soft hammer as necessary to disengage from splines. Install differential case in rear axle housing *(see "Rambler Hypoid" Rear Axle).*

VALIANT HYPOID

Valiant (1960)

►*PINION BEARING PRELOAD ADJUSTMENT NOTE:* Bearing preload specifications of 13-20 inch pounds is for **new** bearings. If used or run-in bearings are re-installed, bearing preload should be 0-10 inch pounds.

►*PINION SHAFT NUT TIGHTNESS NOTE:* On early cars, built before Jan. 1, 1960 pinion shaft nut must be checked for proper tightness. Tighten to 240 ft. lbs. If nut is found to be less than 240 ft. lbs., check turning torque of pinion shaft after tightening nut. If turning torque exceeds 30 inch pounds, readjust pinion bearing preload.

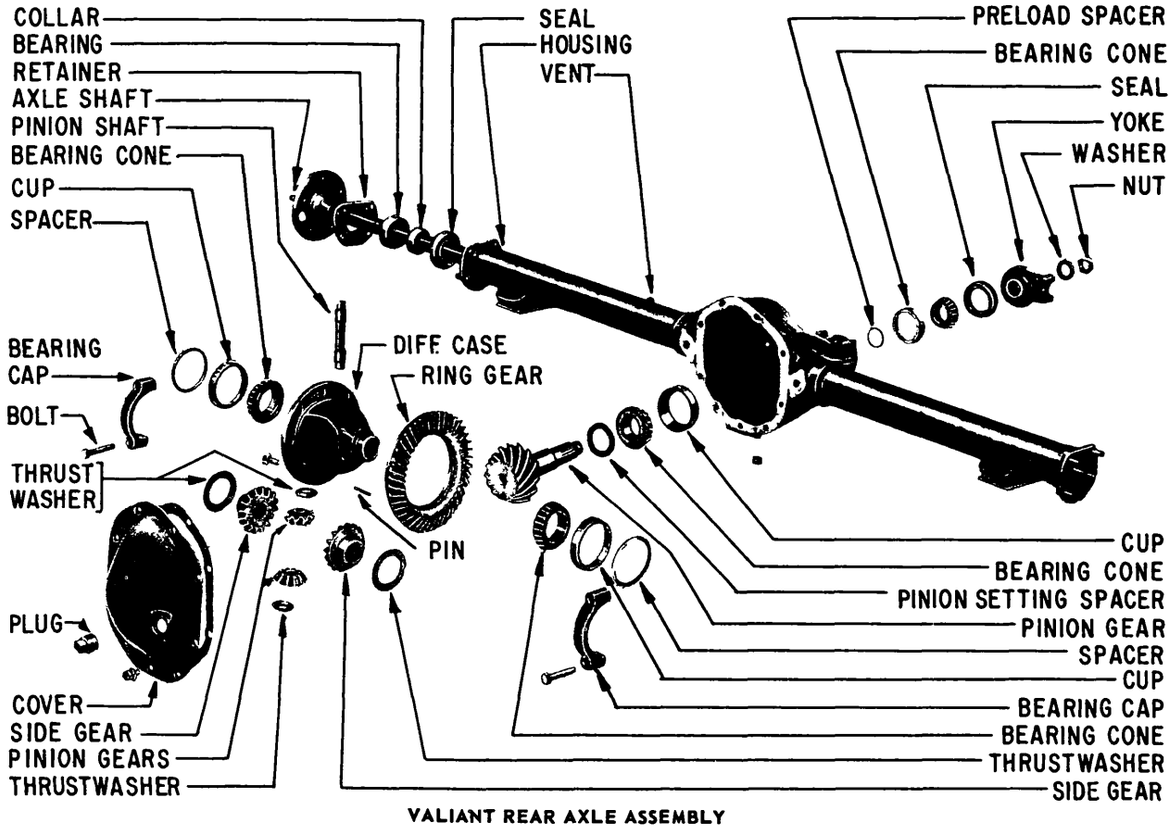
DESCRIPTION: Semi-floating, hypoid gear type with differential carrier integral with rear axle housing.

REMOVAL: *See "Rear Axle" on Car Model page.*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Car Model page.*

OVERHAUL

DIFFERENTIAL CASE: Place rear axle assembly in a suitable holding fixture, then drain lubricant from housing and remove cover. Clean interior of housing and gears with solvent. Before removing differential case, check the following:



Ring Gear Runout - Check for differential side play (there should be none). If there is no differential side play, mount dial indicator, Tool C-3339 on pilot stud, Tool C-3288 and load indicator slightly when plunger is at right angle to back face of ring gear, then set indicator dial to zero. Turn ring gear several revolutions and mark ring gear and differential case at point of maximum runout. Total indicator reading should not exceed .005".

R moval: Mark carrier and differential bearing caps for installation at the same locations, then remove bearing caps. Install spreader, Tool C-3721 on rear axle housing with tool dowels seated in locating holes in housing, then turn tool screw finger tight (in direction to spread housing). Screw pilot stud, Tool C-3288 in one side of carrier and install dial indicator so indicator arm is against opposite side of carrier on centerline of axle shafts. Spread carrier approximately .012-.015" (DO NOT exceed .020"), then remove dial indicator. Remove differential assembly from rear axle housing. *NOTE - Release tension on spreader tool but do not remove it from rear axle housing until reassembled differential case is installed for side bearing preload adjustment.*

Disassembly: Mount differential case assembly in a vise having soft jaws, then remove ring gear attaching bolts. *NOTE - Ring gear attaching bolts are LEFT HAND Thread.* Drive differential pinion shaft lock pin out of case from ring gear side, then remove differential pinion shaft by driving it out with a brass drift. Rotate differential side gears to remove pinion gears and thrust washers, then remove differential side gears and thrust washers. Remove differential bearings with Tool C-293 and No. 39 plates.

Inspection: Wall all parts in solvent and blow dry with air. Inspect gears for worn, chipped or damaged teeth and inspect thrust surfaces, including thrust washers for scoring, wear or damage. Inspect pinion shaft for pitting, scoring, or wear. Replace all parts as necessary.

Reassembly: Install thrust washers on differential side gears and position gears in case, then place thrust washers on both pinion gears and mesh pinion gears with side gears. Rotate gears to align pinion gears and washers with shaft holes in case. Install pinion gear shaft with hole in shaft aligned with lockpin hole in case. Be careful not to damage thrust washers when installing shaft. Install lockpin from ring gear side of case. Position ring gear on case and start all bolts through case into ring gear, finger tight. Tap ring gear against flange and tighten bolts to 30 ft. lbs. *NOTE - These bolts have LEFT HAND threads.* Install side bearing cones with Tool C-3716.

VALIANT REAR AXLE ASSEMBLY

Differential Side Bearing Preload Adjustment: After pinion shaft assembly is removed from rear axle housing (see below), spread housing as outlined for differential case removal (above) and install differential case assembly in rear axle housing, with bearing cups on bearing cones. Select and install spacer washers which, when installed between cups and housing will leave a small amount of free play. *NOTE - Spacer washers are available in .003" variations from .254" to .284".* To measure endplay, use two sets of feeler gauges. Push differential case to one side of rear axle housing as far as it will go. Insert feeler of greatest possible thickness between cup and spacer on opposite side above centerline of housing, then insert the same thickness feeler gauge of the other set between came cup and spacer, below centerline of housing. Rotate differential bearings several times to align bearings, then increase thickness of feeler gauges, if possible, to provide a hard drag. Select two new spacer washers having a total thickness equal to the two spacers installed for trial, plus thickness of feeler gauge, plus .003-.006". As an example: If two .257" spacers were used for trial purposes and a .012" feeler gauge was the maximum thickness inserted between cup and spacer, two .263" spacers would produce zero end play. As proper preload is made with spacer washers which add .003-.006" to zero endplay, the thickness of one spacer would be .263" and the other .266" for minimum preload, and two .266" spacers would be used for maximum preload. Remove differential assembly from housing and tie selected preload washers to bearing cups to have them available for use in determining backlash (see below).

PINION: Removal - Remove pinion nut and yoke with puller, Tool C-452 and holding Tool C-3281, then remove pinion oil seal with puller, Tool C-748, Remove pinion front bearing and preload spacer washer. Remove pinion from carrier, then remove pinion bearing cups with a flat faced drift. Remove pinion rear bearing from pinion shaft with puller, Tool C-293 and No. 40 plates.

Pinion Bearing Cup Installati n: Start both bearing cups into rear axle housing, then place rear spacer, Tool SP-3244 on main part of Tool 3715. Seat pinion rear bearing on spacer and hold tool in rear axle housing. Place centralizing sleeve, Tool SP-3245 on tool and place pinion front bearing cone on centralizing sleeve,

CONTINUED ON NEXT PAGE

VALIANT HYPOID (Continu d)

then tool compression sleeve, and centralizing washer and nut. Draw cups tightly against shoulders in rear axle housing by tightening the nut while holding compression sleeve from turning with Tool C-3281. *NOTE - Permit tool to turn to sev ral locations during tightening op ration to avoid brinneling the bearings.* Leave tool in rear axle housing to determine pinion setting.

Pini n S tting (With Tool C-3715): With main tool left in rear axle housing after installing pinion bearing cups, loosen tool nut and retighten to produce 10-15 inch pounds of turning torque. Attach gauge block to main tool. Place cross bore arbor in housing and install bearing caps. Tighten cap bolts lightly. Select a spacor washer which will fit between arbor and gauge block when washer is flat on block. *NOTE - Spacer washers ar availabl in .002" variations from .084" to .100".* The fit should have a definite drag, similar to pull of a feeler gauge. *NOTE - Should a washer have a littl drag and the n xt thicker washer will not pass through, us thinner washer.* This washer is the proper one for use in the rear axle housing being checked providing the pinion has a "0" (zero) marking. If the pinion being used has a "+2" marking, select a washer **.002" thinn r.** If the pinion being used has a "–2", select a washer **.002" thicker** for installation. Pinions having other markings should be handled in a similar manner. Remove tools from housing.

Installati n: Place selected pinion setting spacer washer (see above) on pinion shaft with chamfered side toward pinion gear, then use Tool C-3717 and an arbor press to press bearing on pinion. Hold pinion in rear axle housing and install original pinion bearing preload washer (chamfered side toward shoulder), then install front bearing, yoke and nut on pinion shaft. Turn rear axle housing to bring pinion shaft yoke upward, then tighten nut to 240 ft. lbs. (minimum), using holding Tool C-3281 on yoke to hold the assembly in several positions to make a complete revolution while tightening. Remove holding tool and rotate assembly several turns in both directions to align bearing rollers. *NOTE See "Pinion Bearing Preload" below for installation of oil seal.* Adjust pinion bearing preload.

Pinion Bearing Preload Adjustment: With pinion yoke upward, test preload with Tool C-685 (torque wrench) by noting torque wrench reading required to turn pinion shaft through several turns. *NOTE - Wrench must be moving when readings are taken.* If preload is 13-20 **inch pounds** (new bearings); 0-10 **inch pounds** (used bearings), preload is correct. If not, use a **thicker** washer to **decrease** preload and a **thinner** washer to **increase** preload. *NOTE - Preload washers are available in .002" variations from .074" to .106".* When preload is correct, remove nut and yoke. Apply a thin coating of sealing compound to inner bore of housing in area of pinion seal, then install pinion oil seal (lip toward bearing) with Tool C-3656. Install yoke with tools C-3718 and C-3281. Install washer with cupped side toward yoke, then install nut and tighten to 240 ft. lbs. minimum.

Drive Gear & Pinion Backlash Adjustment: With pinion gear properly adjusted, attach spreader, Tool C-3721 and spread rear axle housing *(see "Differential Case Removal" above),* then install differential case assembly and pre-selected differential bearing preload spacers in housing. Release tension on spreader tool and install bearing caps. Tighten bolts to 40 ft. lbs. Attach a dial indicator to housing so indicator actuating arm is in contact with one tooth, parallel to ring gear rotation. Check backlash and mark the gear tooth, then re-check backlash on three other teeth approximately 90° apart. When minimum backlash position is located, use dial indicator at that tooth only. If backlash is not within limits of .004-.006", adjust by using different thickness spacers on both sides of differential case. Any change in one spacer must be compensated for by a similar change in other spacer. The total thickness of both spacers must be the same after backlash adjustment as before in order to maintain correct preload. When backlash is correct, check gear tooth pattern with red lead, then install cover and tighten bolts to 20 ft. lbs.

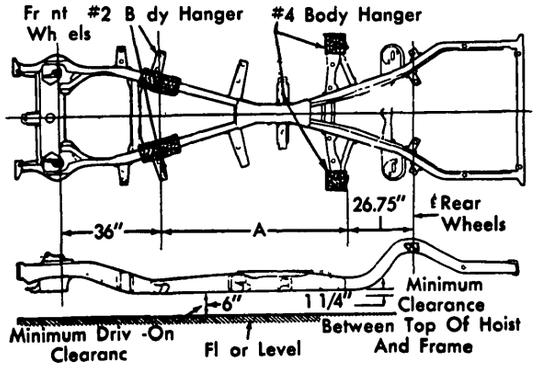
AIR SUSPENSION CONTROL VALVES
Buick, Cadillac 2512
Ford, Mercury 2515
Oldsmobile, Pontiac 2512
Rambler 2512

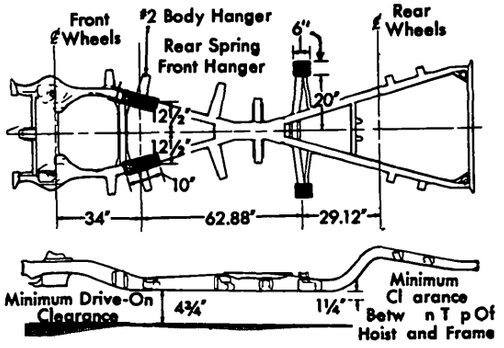
IMPORTANT—Refer to the "Annual Data" for all data on car models later than 1960.

►*CAUTION:* On all Air Suspension cars, and other cars with special frames or Unit Body - Frame construction, special precautions and procedures are required when jacking or hoisting the car as listed below. *For TOWING instructi ns n Air Suspension Cars, see individual car mod l Air Suspensi n Data.*



BUICK
1958-59 MODELS

BUICK (Air Susp nsi n Cars): *NOTE* - Before raising the car on a jack or hoist, pull out manual life knob located below instrument panel to right of center heater air outlet, to place car in full rebound position. Leave knob in OUT position while car is raised.

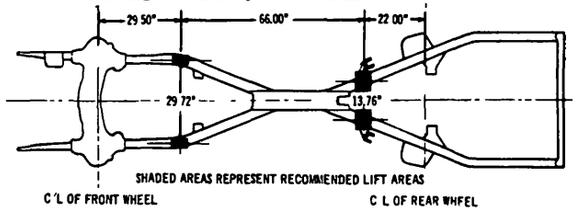


Hoisting Car: Place car in full rebound position (see note above). *CAUTION - D not completely deflate or inflate air suspensi n system (such as opening air lines to let air scape r running engine to inflate system) whil car is on any typ lift that supports front of car by the front spring s ats.*

CADILLAC
1958-60 MODELS

CADILLAC: *CAUTION (CARS WITH AIR SUSPENSION)* - Before jacking, hoisting or towing cars (Exc. Eldorado Brougham), pull the manual valve knob on instrument panel to full OUT position which will raise car to its full rebound position. On Eldorado Brougham, do not

CADILLAC (EXC. BROU HAM) FRAME CONTACT POINTS



ELDORADO BR UGHAM FRAME C NTACT P INTS

open any door or turn on the ignition when any wheel is off ground (changing tire or when car is on a hoist). Air suspension leveling action could cause car to shift on lifting equipment. Never raise rear of car with rear shock absorbers disconnected which could cause car to be lifted off its suspension.

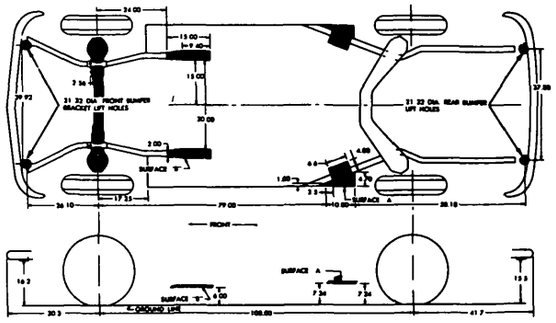
Hoisting Car (All Models): Hoisting equipment of the type that engages suspension, axle, or wheels is preferred. When using this type equipment the necessary precautions must be taken to prevent damaging shock absorber mounts, exhaust pipes and mufflers. When using a frame contact type hoist, special adapters must be used on hoist rails to assure engagement with car frame at locations indicated by shaded areas in illustration. Care should be taken to prevent hoist adapters contacting any part of the No. 2 body hanger. Hoist contact at rear should be at outer ends of No. 4 body mounting brackets. In no case should rear contacts be less than 40" apart. *CAUTION* - Do not allow hoist to contact rear lower control link front mounting bracket.

CHEVROLET
1958-60 PASS. CARS

CHEVROLET: *CAUTION (CARS WITH AIR SUSPENSION)* - Before jacking up any wheel or raising car on a frame contact type hoist (any hoist that does not support car under all four wheels), the manual shutoff valve located on top of junction block at left side of engine adjacent to accumulator tank, must be closed when car is at normal operating height. Be sure valve is opened after removing car from jack or hoist.

CHEVROLET FRAME CONTACT POINTS

Hoisting Car (All Models) - Hoisting equipment that engages suspension, axle, or wheels is preferred. When using this type equipment the necessary precautions must be taken to prevent damaging shock absorber mounts, exhaust pipes and mufflers. When using a frame contact type hoist, special adapters must be used on hoist rails to assure engagement with car frame at locations indicated by shaded areas in illustration. Make sure the manual shutoff valve (see above) is closed before lifting car on this type hoist.



CORVAIR
1960 MODELS

CORVAIR: The integral body design requires that precautions be observed when raising car with a jack or on a hoist.

Jacking the Car (Floor Jack): Place jack directly under side edge of body approximately 8" toward center of vehicle from body door opening as follows: **Front End** - 8" toward rear from front edge of door opening. **R ar End** - 8" forward from rear edge of door opening.

H isting (Fram Contact H ist): If frame contact hoist is used, it must be equipped with proper adapters so that car will be supported at correct points as shown in illustration. *CAUTION - Fuel tank is located behind front axle and ahead of body sill lifting pads. Hoist must not contact tank.*

►*CAUTION:* When rear of vehicle is supported at rear lifting pads and more than 200 lbs. load is placed on rear end, vehicle will teeter (front end will lift) if luggage compartment and fuel tank are empty. *Chain or tie down the front end to assure safety.*

1960 CORVAIR

CHEVROLET TRUCKS
1960 MODELS

CHEVROLET TRUCKS (Vertical Type Jack): Following list of jacking points will assist in performing wheel and tire assembly changes with vertical type emergency jacks supplied with 1960 Chevrolet trucks.

FRONT

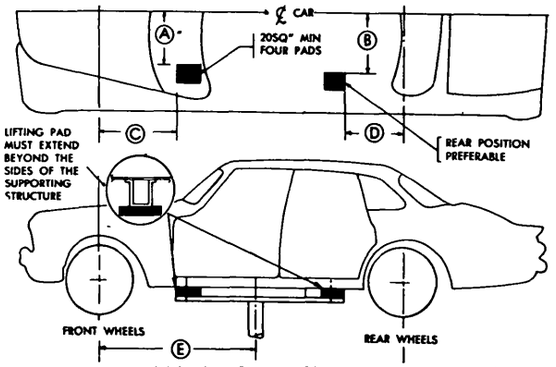
10, 20, 30 Models - Lower arm pivot or torsion bar socket.
40 Models - Frame side rail ahead of steering gear or idler support.
50, 60 Models - Frame side rail behind front crossmember. Use hardwood block between front crossmember and upper control arm to reduce jack travel.

REAR

10, 20, 30 Models - Axle housing.
40 Models - Spring ahead or behind axle.
50, 60 Models - Spring, in front of axle housing.

CHRYSLER, DE SOTO, DODGE PLYMOUTH & VALIANT
1960 MODELS

Integral frame requires that certain precautions be observed when raising car on hoist or jack.



Jacking the Car (Floor Jack): Caution should be used when raising car with floor jack. Locate jack **only** under rear axle housing or under front suspension lower control arms. *CAUTION* - DO NOT contact jack on any part of underbody.

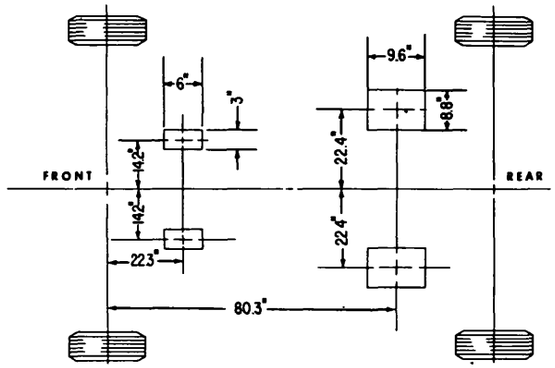
CONTINUED ON NEXT PAGE

CONTINUED FROM PRECEDING PAGE

Hoisting (From Contact Hoist): If frame contact hoist is used to raise car it must be equipped with proper adapters in order that car will be supported in correct position as shown in illustration, and to specifications indicated in table below:

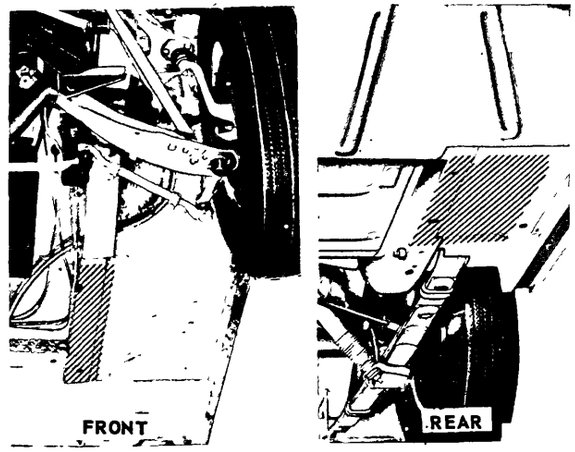
	A	B	C	D	E
Chrysler PC1	16.50"	17.25"	24"	22"	54"
Chrysler PC2,3	16.50"	17.25"	28"	22"	59"
DeSoto			24"	22"	54"
Plymouth	16.50"	17.25"	24"	18"	54"
Valiant	14.2"	16.2"	20.3"	23.7"	48"

CHRYSLER, DE SOTO, DODGE, PLYMOUTH & VALIANT FRAME CONTACT POINTS



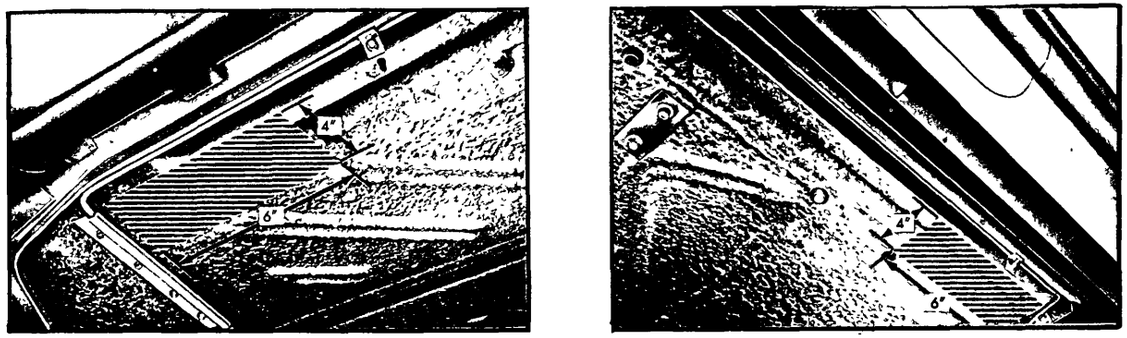
COMET, FALCON, THUNDERBIRD

1958-60 MODELS



Jacking the Car: When a stationary floor jack or a roll jack is to be used there are several specific recommended points of contact: Either side of car may be raised at front by jack contact at lower arm strut connection. Either side of front end may be raised by jack pressure on front crossmember or crossmember to which stabilizer is connected. Either side of rear end may be raised by jack pressure on rear crossmember. DO NOT put pressure on fuel tank. To raise front of car with bumper jack, position jack directly in front of parking lights. At rear, place jack under tail light midway between bumper attaching bolts.

Hoisting the Car: All drive-on type hoists should be checked first for possible interference between hoist rails and car underbody. Hoists should be modified and approach ramps built up to provide necessary clearance.



Rail Type & Fork Lift (Twin Post) Hoists - Front adapters or hoist plates must be carefully positioned to contact lower suspension arms and must be large enough to cover entire spring seat area. Rear adapters or forks must be positioned under rear axle (forks must not contract axle at points more than 1" outboard from circumference welds near differential housing). *CAUTION* - Raise car slowly and check to make certain that rear shock absorbers are not damaged.

COMET FRAME LIFT DIMENSIONS

FALCON FRAME CONTACT POINTS

FRONT FORD THUNDERBIRD FRAME CONTACT POINTS REAR

Frame Contact Hoist - Frame contact hoist adapters are necessary to lift car. The hoist adapter pads should each cover at least 12 square inches (Falcon) or 24 square inches (Thunderbird) of underbody areas shown in illustrations.

FORD & MERCURY

1958 MODELS

FORD AND MERCURY *(CARS WITH AIR SUSPENSION):* *CAUTION* - Do not open any door or turn on the ignition when any wheel is off ground (changing tire or when car is on a hoist). Air suspension leveling action could cause car to shift on lifting equipment.

Hoisting Car: (Air Suspension Units Inflated): Hoisting equipment of the type that engages suspension, axle, or wheels *(see "Two-Post" hoist not below)*, is preferred. When using a frame contact type hoist, make certain that proper adapters are used to prevent contact with rear shock absorbers or suspension links.

►*TWO-POST HOIST NOTE:* At the rear, make certain rear axle housing centers over hoist post center. Check where rear saddle jaws will contact rear axle. If necessary use special adapters to prevent damage to rear shocks, track bar, gas tank, etc. In instances where front air springs are extremely low or deflated the front hoist rail will contact oil pan and may result in damage to oil pan, oil pump and vacuum pump. If available, install shipping pedestals *(see "Hoisting Car, Air Suspension Units Deflated" below)*. If pedestals not available, install small wooden blocks between lower suspension arm and hoist saddles to provide clearance for oil pan.

Hoisting Car (Air Suspension Units Deflated): Jack up car at front and rear and install shipping pedestals *NOTE* - These may be procured from car dealer. Front pedestals are installed between lower arm jounce bumper and its contact surface on side of upper spring "beehive" on frame. Rear pedestals are installed between rear axle housing and rear axle bumper. Lower jack and allow weight of car to rest on pedestals.

CONTINUED ON NEXT PAGE

JACKING & HOISTING PRECAUTIONS

CONTINUED FROM PRECEDING PAGE

LINCOLN & CONTINENTAL

1958-60 MODELS

LINCOLN & CONTINENTAL: *CAUTION* - Because of the new body-frame unitized construction, serious damage may result from improper jacking and hoisting.

Jacking th Car (Fl r Jack): Jack should be placed under lower suspension arms at front and rear axle at rear of car, raising each wheel individually. *CAUTION* - When jacking against sheet metal, a wooden block (2" x 4") of suitable length should be used to prevent denting or deforming metal. *DO NOT* attempt to raise one entire side of car by placing jack midway between front and rear wheels.

Bump r Jack - A 1¼" hole is provided in each bumper mounting bracket at underside of front and rear bumpers. End of bumper jack hook should be positioned in this hole. Be sure wheels are blocked and transmission is in "P" (Park) position.

Hoisting Car: *(NOTE* - When using a rail type hoist or a twin post hoist, special adapters may be required to avoid damaging rear shock absorbers and to fully encompass the wider front lower control arms).

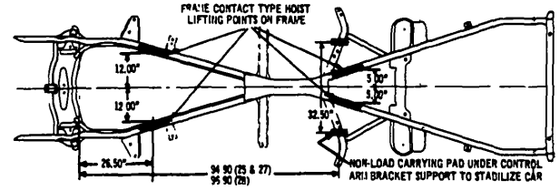
Frame C ntact Hoist - Special pads located on underside of body floor pan adjacent to each wheel are provided for use with frame contact type hoist. These pads are corrugated (front), plain (rear) and special adapters must be used, if necessary, for frame type hoist to contact all four points. *CAUTION - Do not allow hoist pads r adapter arms t contact body floor pan.*

OLDSMOBILE

1958-59 MODELS

OLDSMOBILE (Air Suspension Cars): *CAUTION* - Before disconnecting air lines, working under car, or raising car on a hoist, the following precautions must be taken to prevent personal injury or damage to the car.

Raising Car (On a Jack) - Raise car in same manner as with conventional suspension (**do not** pull out on air suspension manual lift knob). When jack is lowered at right or left front of car, front end will follow jack down to slightly below normal, but will automatically raise to correct level. When jack is lowered at right or left rear, only the side supported by the jack will follow jack to slightly below normal position.



Raising Car (On Frame-Contact Hoist) - Wheels will drop and exhaust air from air springs. When hoist is lowered, car frame may continue to rest on hoist until air springs are inflated (it may be necessary to start engine for sufficient pressure). *CAUTION* - Do not pull out on air suspension manual lift knob while car is in a raised position.

Raising Car (On Twin-Post Hoist) - Use caution to prevent left hand yoke of rear hoist contacting hydraulic brake hose or junction block on rear axle housing.

PONTIAC

1958-60 MODELS

PONTIAC: *CAUTION (CARS WITH AIR SUSPENSION)* - Before jacking, hoisting or towing, raise car to its maximum height by pulling out on "Car Lift" knob located on underside of instrument panel to left of steering column. After work completed, return knob to the "In" position. *CAUTION* - If car has been raised with "Car Lift" knob in the IN position, DO NOT pull out knob while car is supported on a twin post hoist or by jacks under the front lower control arms. This action would cause lower control arms to swing down and might cause car to slide off hoist or jacks.

PONTIAC FRAME CONTACT POINTS

Hoisting Car (All Models): Hoisting equipment of the type that engages suspension, axle, or wheels is preferred. When using this type equipment the necessary precautions must be taken to prevent damage to shock absorber mounts, exhaust pipes and mufflers. When using a frame contact type hoist, adapters must be used to contact the X-type frame at points indicated in illustration. Non-load carrying pad (or block) must be used between hoist and frame outrigger as indicated in illustration to prevent shifting or movement of car on hoist. *CAUTION* - Rear support points are only 5" out from center line of car and car will not be stable on hoist unless these non-load carrying pads are installed.

1954-56 BUICK

All Series (1954-56)

►CHANGES & CORRECTIONS

►*STABILIZER BAR INTERFERENCE CORRECTION:* If water outlet hose on radiator contacts the stabilizer bar, insert a spacer under left hand stabilizer bracket to provide a minimum of 3/16" clearance between hose and stabilizer

►*1955 LOWER CONTROL ARM OUTER PIVOT PIN & BUSHING POSITION CHANGE* Head of bushing has been reversed so it will be toward front of car on right side, and toward rear on left side.

►*1955 BRAKE PIPE INTERFERENCE WITH UPPER CONTROL ARM CORRECTION·* A clip, Part No. 1334584 should be installed over brake pipe and secured to right frame side rail to hold brake pipe away from upper control arm. Bend pipe away from contact with control arm.

►*1956 FRONT TIRE RUBBING ON FRAME CORRECTION (Turning Angle Too Great).* To correct, install a 1/32" thick plain washer under bolt head of rear steering arm bolt on both right and left sides. In order to install washer, it will be necessary to remove hub and drum assembly to gain access to nut on rear steering arm bolt.

►*1956 CASTER CHANGE* Caster now specified is 0° to Neg. 2°, with Neg. 1° desired. This supersedes previous specification of Pos. ½° to Neg. 1½°.

DESCRIPTION: New design with Direct Acting Shock Absorbers and Upper Support Arm pivoted on bracket shaft mounted on frame front cross-member as follows:

Front Shock Absorbers—Delco direct acting hydraulic type located within the coil springs. Upper end is mounted in tower bracket on frame cross-member (bayonet type end with rubber grommets in bracket), lower end is bolted to bracket bolted on underside of spring seat on lower support arm ("eye") type with rubber grommets on mounting bolt). Shock absorbers are interchangeable from right-to-left and can be removed and installed without disturbing suspension.

►*CAUTION—Shock absorber calibrations differ in some models and are not interchangeable from one car to another.*

Upper Support Arm—New assembly (furnished with shaft, bushings, and dirt seals) mounted at inner end on frame cross-member by two bolts in pivot shaft. Shaft and bushings can be replaced separately.

CHECKING & ADJUSTING: Check front wheel bearings, wheel runout, tire inflation, and front end trim dimensions, and see that car is at curb weight before checking front end alignment.

Tire Inflation—24 lbs. cold (after standing for more than 3 hours or driven less than 1 mile), **26 lbs.,** (after car driven more than 3 miles at less than 40 MPH), **28 lbs.** (after car driven more than 3 miles at more than 40 MPH).

Trim Dimension (Front Springs): Before measuring, bounce both ends of car up and down several times to make sure there is no bind in suspension members, and to let springs take a natural position. When car is at rest, measure the trim height between top side of lower control arm and underside of frame cross-member (at bumper bracket). Trim dimension should be within limits shown in table below and lower control arm heights should be same on both sides of car.

►**Trim Dimension Correction**—If trim dimension is less than specified, or additional height is required to prevent "bottoming", install additional spring insulators, divided between upper and lower ends of spring. If more than three additional shims required, replace the spring NOTE—New springs should not increase the trim dimension more than 1" over specified maximum limit.

Front Trim Dimensions

46C 56C, 76C, 100	3½-4"
All Other Models	3¾-4¼"

NOTE - When checking new car add ¼".

Kingpin Inclination: (1954-55) 0° crosswise with 7/8° camber. Not adjustable.
(1956) 7° at 7/8° camber.

Caster: (1954-55) Neg. ¼° desired (Limits Pos. ½° to Neg. ¾°). Both sides of car should be equal within ½°. **(1956)** 0° to Neg. 2° (Neg. 1° desired). *NOTE* - Supersedes previous specification of Pos. ½° to Neg. 1½°. **Adjustment** - Remove lubricant fitting from bushing at outer end of upper support arm (front bushing right side, rear bushing left side), loosen clamp bolt in upper end of knuckle support, use Allen wrench inserted through lubricant fitting hole and turn pivot pin to adjust caster. *CAUTION* - Camber will be changed unless pivot pin rotated in complete turns only - check camber after adjusting caster.

Camber: Pos. 3/8° desired (Limits Pos. 7/8° to Neg. 5/8°). Both sides of the car should be equal within ¾°. **Adjustment** - Adjust in same manner as Caster (above) except that eccentric pin should be turned only slightly from point where correct caster secured (entire range of adjustment secured in ½ turn).

Toe-In: 0" to 1/16" (1954), 1/16" to 1/8" (1955-56).

Adjustment—Loosen clamp bolt at each end of adjusting sleeve at outer end of each tie rod, turn each adjusting sleeve equally to adjust toe-in. *NOTE*—Threads at each end of the sleeve should be equal and slots in sleeve and clamp should be aligned.

Toe-Out on Turns: Inner wheel turns 22½° ±¾° with outer wheel turned 20° No adjustment.

►*DYNAFLOW CARS (WITH POWER STEERING) NOTE: A special shim, Part No. 1290142, is used on the upper end of LEFT front spring between spring and insulator.*

►*REAR SPRING NOTE—See "Buick Rear Suspension" in Rear Axle Section for standard and special rear springs.*

Front Spring Application

Series	Standard	Air Conditioned
40, 60 (1954 Synchro-mesh)	.1165046①	1165048
40, 60 (1955 Synchro-mesh)	1167272④	1165048

50 (1955 Synchro-mesh)	.1167273②	1165049
40, 60 (1954 Dynaflow)	1165047②	1165049
40, 60 (1955 Dynaflow)	1167273②	1165049
50 (1954-55 Dynaflow)	1165048③	1165050
70 (1954-55 Dynaflow)	1165049	1165050
100 (1954)	1165049	
40 (1956 Synchro-mesh)	1171037⑤	1165048
40, 60 (1956 Dynaflow)	1171038	1165049
50, 70 (1956 Dynaflow)	1165049	1165050

①—No. 1165047 200 lb. overload (Except Series 40 Convertible & Series 60 Estate Wagon).
②—No. 1165048 200 lb. overload
③—No. 1165049 200 lb. overload.
④—No. 1167273 200 lb. overload (Except Series 40 Convertible & Series 60 Estate Wagon).
⑤ - 1171038 300 lb. overload.

FRONT SPRING REPLACEMENT (Removal): Place jack under lower control arm and raise sufficiently to remove wheel. Disconnect stabilizer link from lower control arm and outer end of tie rod from steering arm. Remove shock absorber and remove lower pivot pin nut, pivot pin nut, pivot pin, lock washer, and dust seals. Support car frame with another jack, then slowly lower jack under lower control arm, and remove spring.

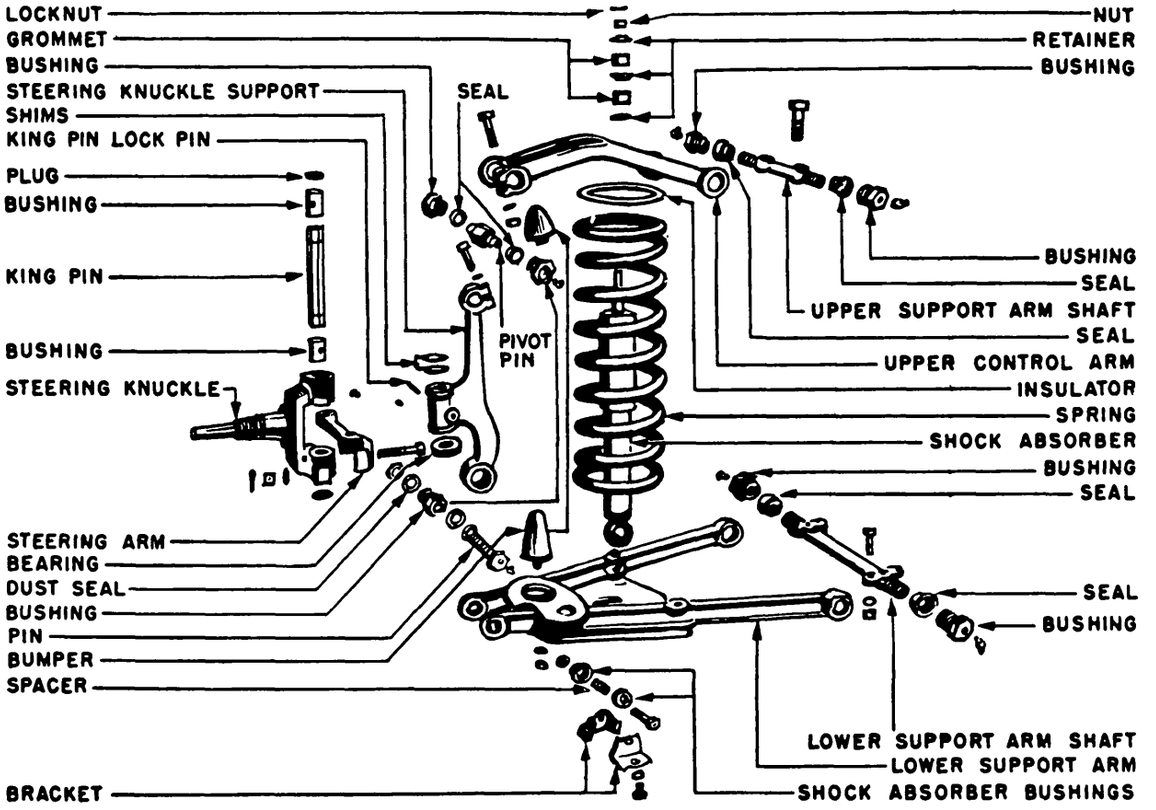
Installation: Before installing front spring, check the spring part number to make sure it is the correct spring (See "Front Spring" Table above). Make sure that rubberized fabric spring insulator is around spring centering flange on frame and is in good condition. Place one end of spring over centering flange, and as lower control arm is raised, position lower end of spring so that end coil seats in recess in spring seat. Support lower control arm on a jack. Slip lower pivot pin dirt seals over outer ends of lower control arm. Centralize lower end of knuckle support between outer ends of lower control arm, then install lower pivot pin and lock washer from front side and tighten securely. Install and tighten nut. Snap dirt seals into place over pivot pin Connect tie rod outer end to steering arm, and connect stabilizer link to lower control arm (NOTE—When stabilizer rod nut is tightened, the overall length of each grommet assembly should be 1 11/16". Adjust nut as necessary to obtain this dimension) Reinstall shock absorber and wheel. Adjust front end alignment

SHOCK ABSORBER REPLACEMENT: Not necessary to disturb front suspension assembly.

Removal: Hold upper mounting stem with a wrench, remove palnut and retaining nut (on top of shock absorber mounting bracket in engine compartment), lift off upper retainer and rubber grommet. Remove bolts and lockwashers attaching lower mounting bracket to underside of spring seat on lower support arm, pull shock absorber and mounting bracket assembly down through opening in spring seat. Do not lose retainer and grommet on shock absorber mounting stem To remove shock absorb-

CONTINUED ON NEXT PAGE

1954-56 BUICK (C nt.)



er from lower mounting bracket, remove pivot bolt and nut, pull bracket off, remove rubber grommets and spacer from shock absorber eye.

Installati n: Check to make sure the correct shock absorber is being installed *(See "Shock Absorbers" on Car Mod l page)*, then reverse the removal procedure as given above.

UPPER SUPPORT ARM REPLACEMENT (Removal): Remove generator and engine front mounting nuts, and raise engine just enough to allow removal of support upper arm shaft bolts. Remove pivot pin and bushings from support arm by taking out the pivot pin clamp bolt and turning bushings out of support arm. Remove rubber seals. Loosen clamp bolt in knuckle support and remove pivot pin, using a ½" hex Allen wrench. Remove support arm shaft attaching bolts and remove support arm assembly from car. Unscrew shaft bushings and remove shaft and seals from arm.

Installati n: *(CAUTION–Before installing any new parts, check the distanc between the two shaft bosses at inner nd of support arm assembly–this distance should b 6 5/16"± .020").* Install a rubber seal over each end of upper arm shaft, with large or bell end of seal outward. Insert one end of shaft with a seal, in one end of upper arm, and force other end of shaft into opposite end of arm. Fasten upper control arm securely in vise (close to one end of arm to avoid spring or distortion). Apply a liberal amount of white lead or Lubriplate to both bushings before installing. Start first bushing on shaft and into upper support arm at same time. Turn bushing until head is tight against arm, then tighten to 100 (1954-55), 150 (1956) ft. lbs. Center the shaft between ends of arm and install second bushing in same manner as first bushing, tightening the second bushing so that no binding exists. Before installing support arm, turn the shaft to locate the bolt holes equally distant from ends of arm, then bolt shaft to frame front front cross member. Lower engine and tighten front mounting nuts. Reinstall upper pivot assembly as follows: Hold knuckle support in line with hole through support arm and screw pivot pin into knuckle support, with adjusting wrench hole in pin toward split side of control arm. Turn pivot pin until large diameter section is centralized in knuckle support and tighten clamp bolt. Install rubber seals on both ends of pivot pin. Centralize knuckle support boss in support upper arm yoke and start the externally threaded bushing on threads of pivot pin and into threads of control arm. Start the plain (grooved) bushing on threads of pivot pin, then turn the opposite bushing up tight. Turn plain bushing until hex is just clear of arm, then install and tighten clamp bolts. Check and adjust front end alignment.

LOWER CONTROL ARM REPLACEMENT (Removal): Remove front chassis spring, then remove lower control arm assembly from frame front cross member.

BUICK FRONT SUSPENSION

Bushing Replacement: *(CAUTION–Before installing any new parts, check the distance between the two shaft bosses at inner end of support arm assembly (this distance should be 11¼"" ± 1/32").* Install a rubber seal over each threaded end of new control arm shaft, with the large or bell ends of seals outward toward ends of shafts. Insert one end of shaft with a seal in place in one control arm end and force opposite end of shaft into other control arm end (a piece of wood approximately 1¼" x 2½" x 24" can be used as a pry). Fasten control arm securely in a vise (close to one end of arm to avoid spring or distortion). Apply a liberal amount of white lead or Lubriplate to both bushings before installing. Start first bushing on shaft and into control arm at same time. Turn bushing until head is tight against arm, tighten to 100 (1954-55), 150 (1956) ft. lbs. Center shaft between arms and install the second bushing, turning shaft as required to thread into bushing so that no binding exists.

Installation: Before installing lower control arm and shaft assembly, turn shaft to locate bolt holes at both ends so they are equally distant from the inside surface of arms, then bolt shaft to frame front cross member. Install chassis spring and other parts, and check and adjust front end alignment.

STEERING KNUCKLE REPLACEMENT (Removal): Remove front wheel with hub and drum assembly. Remove brake backing plate and steering arm from steering knuckle (Do not disconnect brake hose but support backing plate out of way to avoid strain on hose). Drive out kingpin lockpin. Remove upper welch plug from knuckle by piercing with a sharp pointed punch and prying out. Drive kingpin down and out, which will drive lower welch plug from knuckle. Remove thrust bearings and shims.

Installation: Reverse removal procedure and use shims as required between knuckle support and upper boss of knuckle to provide .003" endplay of knuckle on support. Use new welch plugs at each end of kingpin. Check and adjust front end alignment.

1957-58 BUICK FRONT SUSPENSION

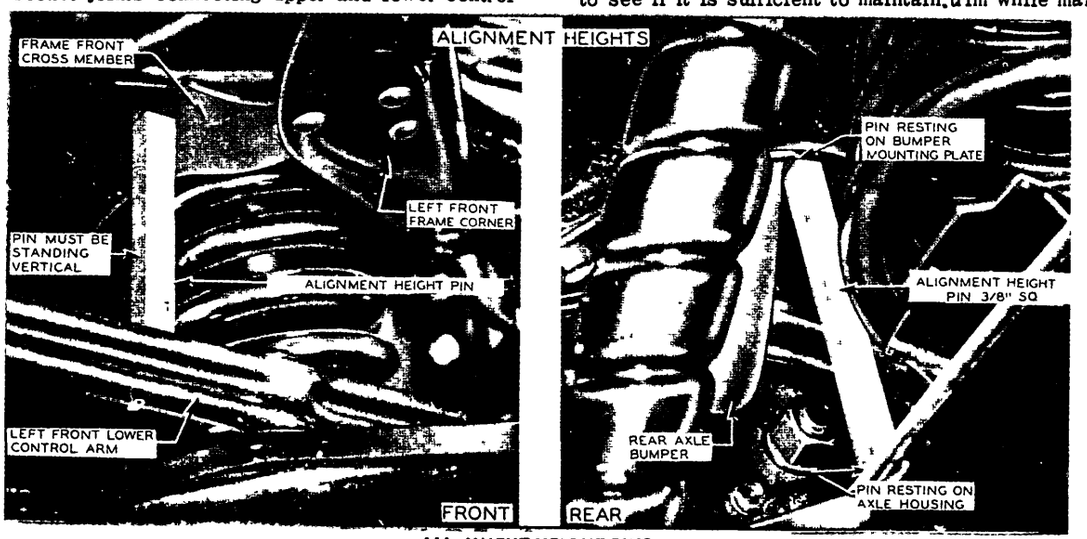
All Series (1957-58)

►CHANGES, CAUTIONS, CORRECTIONS

►*1957 LOWER CONTROL ARM-TO-FRAME BOLT PRODUCTION CHANGE & TIGHTENING CAUTION:* Two different type bolts have been used at this location. On early cars, bolts having three radical marks in head should be tightened to 55-65 ft. lbs. *(CAUTION - Do not tighten in excess of this specification).* Later cars have bolts with six radial marks in head. Tighten these bolts to 70-80 ft. lbs. A special hardened steel plate, Part No. 1180406 is used with the later type bolts. The normal length of the later type bolts is 1¾", however, a few cars were produced with 1½" bolts. On these cars, if shimming of lower control arm is necessary, the longer bolts must be installed. *If bolts are to be replaced for any reason, be sure and install the later type together with the hardened steel plate.*

►*1957 TIE ROD INTERFERENCE (POWER STEERING CARS):* If an interference condition between outer and of intermediate rod and tie rod exists, it may be caused by the head of the cotter key used to lock plugs in end of intermediate rod rubbing against tie rod. Correct by loosening idler support arm attaching bolts and positioning idler arm support rearward as far as possible. It may also be necessary to change position of cotter key 45°, so that head of key is at rearward side of intermediate rod.

►*1957-58 LOWER BALL JOINT LOOSENESS NOTE:* **With car raised (no load on front wheels), the lower ball joint is loose and no corrective measures should be taken unless the looseness, measured at outer circumference of tire is greater than ¼" laterally. If movement of front wheel exceeds this specification, replace lower ball joint.**



DESCRIPTION: "Ball joint" type suspension with ball and socket joints connecting upper and lower control arms to steering knuckles Coil springs or air springs are mounted between lower control arms and frame front crossmember and the shock absorbers are mounted adjacent to springs on lower control arm and attached to bracket on frame side rail at a point between spring and steering knuckle. Control arm shafts are bolted to frame crossmember and are connected to control arms by threaded type bushings.

ADJUSTMENT

CHECKING & ADJUSTING: Before checking or adjusting front suspension alignment, inflate tires to specified pressure. Check front wheel bearings for looseness and correct as necessary. Check for runout of wheels and tires and correct to within limit of 1/8" runout at side of tires. Check for looseness at upper ball joints and tie rod ends and correct if found excessive. Bring car to height specified below.

►*CAMBER & CASTER ALIGNMENT NOTE (CARS WITH COIL SPRINGS):* Place a 3/8" square pin 3 21/32" (1957), 3 29/32" (1958) long between frame and front lower control arm at each front wheel (see illustration), making sure that pin is standing vertical and not leaning. Use sandbags or other weight to hold car down on pins. Bring rear of car to proper trim height *(See "Buick Rear Suspension").* If the gas tank is full, trunk empty (except for spare tire), and if car is bounced and allowed to settle, it may then be considered at proper trim height. If these conditions cannot be met, a 3/8" square pin 5 13/32" (1957), 5 19/32" (1958) long should be placed between axle housing and frame at each rear wheel location (see illustration). Use sandbags or other suitable weight to hold car down on pins.

►*FRONT END ALIGNMENT NOTE (CARS WITH AIR SUSPENSION):* Inflate all tires to proper pressure, then locate car properly on front end equipment. Check tank pressure at top center high pressure tank fitting to see if it is sufficient to maintain trim while making check. Pressure should be 200 lbs. minimum. Check, and if necessary, set front and rear trim heights *(NOTE - For front trim heights, see "Trim Dimension Adjustment" below; for rear trim heights, see "Buick Rear Suspension").* Place car in override position and make necessary corrections for wheel runout by jacking up on wheel, rotating and letting wheel down at point midway between runout extremes. Place override valve in normal position and allow car to settle to trim height. Recheck pressure in tank when car has settled back down If necessary run engine to bring pressure up to minimum of 150 lbs.

ALIGNMENT HEIGHT PINS

Tire Inflation: 24 lbs. (after car has been standing for 3 hours or driven less than 1 mile). **26 lbs.** (after car has been driven for 3 miles or more **below** 40 MPH). **28 lbs.** (after car has been driven 3 miles **above** 40 MPH).

Steering Axis Inclination: Approximately 8° at 0° Camber. Both sides should be within 1° of each other. No adjustment.

►*CAMBER & CASTER ADJUSTMENT CAUTION: Both camber & caster are adjusted by shimming in the same locations, therefore both should be checked before changing either setting.*

►*CONTROL ARM SHIMMING NOTE (FOR CAMBER & CASTER ADJUSTMENT):* If only a small adjustment is required to bring alignment within limits, make shim adjustments at lower control arm. If the amount of shims exceed .160" in any one stack on lower control arms, make adjustments at the upper control arm shafts. Under no circumstances should total shim thickness exceed .160" on lower control arm shafts, and .380" on upper control arm shafts. Replace necessary parts if proper alignment cannot be obtained within these limits.

Caster (1957): Neg. ¼° to Neg. 2¾° (Neg. 1¾° desired), both wheels. *See "Shimming Procedure" below.*

Caster (1958): Pos. ¾° to Neg. 1¾°. Both sides should be within ¾° of each other. *See "Shimming Procedure" below.*

Camber: Pos. 1° to Neg. ½° (Pos. ½° desired). Both wheels should be within ¾° of each other. *See "Shimming Procedure" below.*

Toe-In: 1/16" to 1/8". *(CAUTION - Car must be at curb weight and running height - bounce car and allow it to settle to running height. DO NOT ALLOW ALIGNMENT PINS (see above) TO REMAIN IN POSITION WHILE CHECKING OR ADJUSTING TOE-IN).* Loosen clamp bolts and turn adjusting sleeves at tie rod end as required. Turn right and left adjusting sleeves exactly the same amount but in opposite directions when changing toe-in, in order to maintain front wheels in straight ahead position when steering wheel spoke is straight down. Position tie rod clamps downward to 45° forward to provide frame clearance. *NOTE - It is very important to position bottom face of tie rod end parallel with machined surface at outer end of steering arm when tie rod length is adjusted.*

Turn-Out On Turns (1957): With outer wheel turned 20°, inner wheel should be 23° (Manual Steering), 21¾° (Power Steering). Not adjustable.

Turn-Out On Turns (1958): With outer wheels turned 20°,

CONTINUED ON NEXT PAGE

1957-58 BUICK FRONT SUSPENSION (C ntinued)

inner wheel should be 22°55' (Manual Steering), 22°5' (Power Steering). Not adjustable.

Shimming Procedure: *NOTE - No lower control arm shims are installed in production, however, it is recommended that all shimming required for service adjustments be done at low r control arm shaft providing shim stacks at any one location do not exceed .160". If in excess of this thickness, adjustment must be made at upper control arm shaft. Do not exceed .380" in any one stack at upper control arm.*

Shim Selection (For installation at both upper and lower control arms) - *(NOTE - Upper and lower control arm shaft shims are different and are furnished in sizes indicated in table below).* Adding shims at front location will change **caster toward negative** (Practically no change in camber or toe). Adding shims at rear location will change **cast r toward positive** and camber toward negative (toe toward toe-out). Adding shims at both locations will **not change caster,** but will change **camber t ward negative**

►*SHIMMING AT LOWER CONTROL ARM NOTE:* If shims are added at lower control arm, replace original lower control arm shaft bolts with 300M bolts (½" - 20 x 2"), Part No. 455016. Tighten bolts to 105-120 ft. lbs.

►*SHIMMING AT UPPER CONTROL ARM NOTE:* On right side of car, remove generator and bracket. On left side of car, disconnect battery negative cable. Tighten control arm shaft-to-frame bolts to 90-100 ft. lbs.

1957 L wer C ntrol Arm Shaft Shims

Thickn ss	Part No.
.040"	1179204
.120"	1179205

1958 L wer Control Arm Shaft Shims

Thickn ss	Part No.
.040"	1180938
.120"	1180939

Upper Control Arm Shaft Shims

Thickness	Type ①	Identification ②	Part No.
.060"	Horseshoe	6	1171175
.080"	Horseshoe	8	1172986
.100"	Horseshoe	10	1175585
.060"	Round	6	1175794
.080"	Round	8	1175795
.100"	Round	10	1175796

① - Furnished with either "horseshoe slot" or round hole.
② - Identification number stamped on shim.

►*1957 LOWER CONTROL ARM-TO-FRAME BOLT PRODUCTION CHANGE & TIGHTENING CAUTION:* Two different type bolts have been used at this location. On early cars, bolts having three radial marks in head should be tightened to 55-65 ft. lbs. *(CAUTION - Do not exc d this tightening specification).* Later cars have bolts with six radial marks in head. Tighten these bolts to 70-80 ft. lbs. A special hardened steel plate, Part No. 1180406 is used with the later type bolts. The normal length of the later type bolts is 1¾", however, a few cars were produced with 1½" bolts. On these cars, if shimming of lower control arm is necessary, the longer bolts must be installed. If bolts are to be replaced for any reason, be sure and install the later type bolts with hardened steel plates.

Shim Installation (Lower Control Arm) - To prevent movement of lower control arm shaft on frame member during shim installation, loosen only one bolt at a time. Install shim and tighten bolt before installing shim at opposite end. Tighten bolts to 105-120 ft. lbs.

Shim Installation (Upper Control Arm) - On left side, disconnect negative battery cable from battery. On right side, remove generator and bracket. Wedge bolt heads of all upper control arm shaft bolts to prevent turning, then loosen both bolts on each shaft to free shims for removal. Tighten bolts to 90-100 ft. lbs.

Trim Dimensions Adjustment (Front): *(NOTE - The following dimensions are for a standard car without undercoating or optional equipment and with the car at curb weight. Curb Weight includes gas, oil, and spare tire, but no passengers).* Before measuring trim dimensions, bounce both ends of car up and down several times to make sure there is no bind in suspension members and to let springs take natural position. When car is at rest, measure trim height between front arm of lower control arm assembly and frame at a point between rubber bumper and spring. Measurement must be made as vertical as possible. See table below for trim height limits. When trim dimension is found to be too low, install special 1/8" shims between upper end of spring and frame *(NOTE - If more than three shims are required, replace spring).*

►*FRONT SPRING SHIM NOTE (CAR WITH POWER STEERING):* One spring shim is installed on top of left spring on these cars. None installed on right side in production.

1957 Front Trim Dimensions

Model	Trim Height
46C, 66C, 56C, 76C	4-4½"
Other Models	4¼-4¾"

1958 Front Trim Dimensions

Model	Trim Height
All (With Coil Springs)	①4.70"
All (With Air Springs)	②4.08"

① - Plus or minus .240". ② - Plus .240", minus .120"

REMOVAL & INSTALLATION 1957 MODELS

FRONT SPRING: Removal - Place jack under lower control arm in a position that will not interfere with removal of shock absorber, and raise wheel off floor. Remove wheel and tire. Disconnect stabilizer link and disconnect outer end of tie rod from steering arm. Remove shock absorber *(see "Shock Absorber Replacement" below).* Remove upper ball joint-to-control arm attaching bolts. Support car frame with another jack, then slowly lower jack under lower control arm which will allow lower control arm to drop low enough to remove coil spring without damaging the brake hose *(NOTE - If nec ssary, rem v brak pipe clip and m ve pipe slightly to gain ough slack).*

Installati n: *(NOTE* - Before installing front spring, check the part number stamped on spring to make sure it is correct for the car model. *See "Front Spring Application" below).* Make sure rubberized fabric spring insulator is in place around spring centering flange on frame and is in good condition. Place one end of spring over centering flange, and as lower control arm is raised, position lower end of spring so that end coil seats in recess in spring seat. Support lower control arm on a jack. When lower control arm is raised far enough, install the two upper ball joint-to-control arm bolts with upper bumper pad to rear. Tighten bolts to 70-80 ft. lbs. Connect tie rod outer end to steering arm, and connect stabilizer link. Adjust stabilizer link grommets *(S "Stabilizer Link Grommet Replacement" below).* Reinstall shock absorber, wheel and tire assembly, and adjust camber, caster, and toe-in.

1957 Front Spring Application

Series	Standard	Air C nd.
40 Synchro-mesh	1174155	1174154
40, 60 Dynaflow	1174154	1174153
50, 70 Dynaflow	1174153	1174152

FRONT SHOCK ABSORBER: *(NOTE - Rubber bushings in mounting eyes of shock absorber are not replaceabl . If worn or damaged, the complete shock absorber assembly must be replaced).*

Removal: Raise car by center of frame crossmember far enough to allow removal of upper shock absorber bolt. Remove bolt and shove eye down through opening in frame. Remove bolts and lockwashers attaching lower mounting bracket to spring seat on lower control arm, then pull shock absorber assembly down through opening in spring seat.

Installation: Make sure that replacement shock absorber is correct one for the car model. Insert shock through opening in lower control arm spring seat, and mounting eye up through opening in mounting bracket on frame. Install upper bolt, with nut forward, and tighten to 25-35 ft. lbs. Bolt lower mounting bracket assembly securely to lower control arm spring seat and lower car to floor.

►*1957 SHOCK ABSORBER APPLICATION: See "Shock Absorbers" on Car Model page.*

STABILIZER LINK GROMMET REPLACEMENT: Remove nut from lower end of link rod, then remove rod, spacer, retainer and grommets. When assembling, install rubber grommets dry and use care to center grommets in seats on stabilizer shaft and lower control arm. Also center retainers on grommets before tightening rod nut. Tighten rod nut to limit of thread on rod. When rod nut is tightened to limit of thread on rod, the overall dimension between both grommet retainers should be 1 11/16". If this dimension is not correct, adjust nut as necessary.

BALL JOINT & STEERING KNUCKLE: Removal - Jack up car and support weight on front spring seat. Remove wheel and tire assembly. Remove backing plate-to-steering knuckle attaching bolts and remove backing plate. Do not remove brake hose. Support backing plate out of way to avoid damage to brake hose. Remove bolts through lower control arms and ball joint. Lower steering arm out of the way, and remove rubber bumper from ball

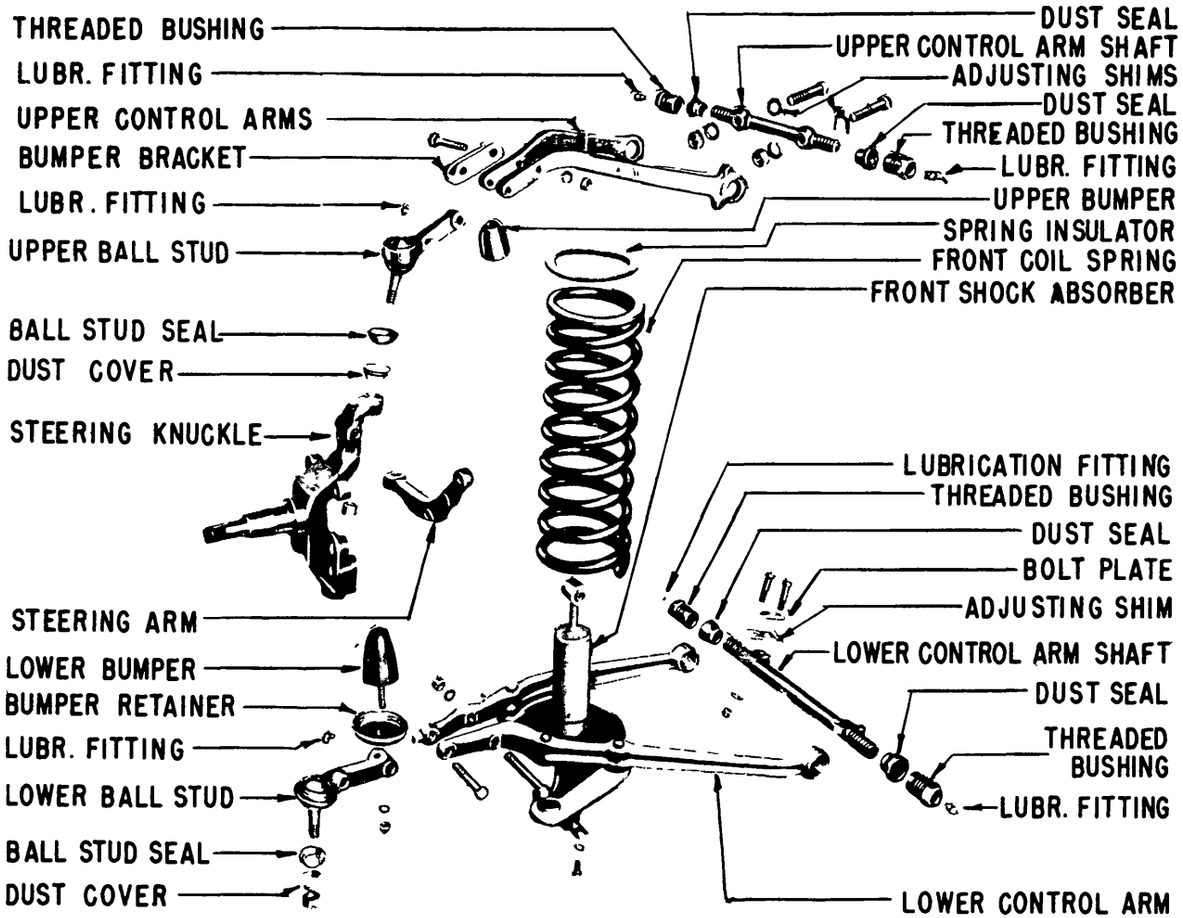
CONTINUED ON NEXT PAGE

1957-58 BUICK FRONT SUSPENSION (C ntinu d)

joint if ball joint is to be replaced. Remove bolts through upper control arms and ball joint. Remove knuckle and ball joint assembly from upper and lower control arms. *(NOTE* - If ball joints are to be replaced, drive directly on studs to remove joints from knuckle. If ball joints are to be reinstalled, care should be taken to avoid damage to threads. This can be done by loosening nuts on tapered studs and installing short bolts half way into nuts. Tighten securely and drive ball joint out of knuckle).

UPPER CONTROL ARM: *NOTE - Upper control arms are not furnished separately, their replacement must be made as an assembly.*

Removal: Jack up car, supporting weight on spring seat and remove wheel and tire. Remove upper control arm-to-ball joint bolts, supporting knuckle and brake drum assembly to avoid damage to brake hose. Remove shock absorber upper mounting bolt and force top of shock absorber down. On right side of car, it will be necessary to remove generator and bracket. Disconnect battery ground strap. Remove shaft attaching bolts *(CAUTION - Remove shims from between shaft and crossmember, noting position and number of shims in each pack).* Remove arm and shaft assembly from car.



Upper Control Arm Shaft & Bushing Replacement - Clamp control arms in vise and remove old bushings and shaft. Apply a liberal amount of Lubriplate to new bushings and ends of shaft. Install bushings and tighten to 150 ft. lbs. Install rubber dust seals on shaft and screw shaft into forward arm so center of attaching bolt hole is 1 9/16" from control arm. Thread rear control arm onto shaft until the distance between front and rear control arms is 7 13/16".

Installation: Using care not to disturb dimension between control arms, install assembly on car by reversing removal procedure. *(CAUTION - Be sure that the shim packs removed at disassembly are installed in their correct positions).* Tighten upper ball joint bolts to 70-80 ft. lbs. Tighten upper control arm shaft-to-shaft bracket bolts to 90-100 ft. lbs. Check and adjust front wheel alignment.

LOWER CONTROL ARM: *NOTE - Riveted parts of lower control arm assembly are not furnished separately.*

Removal: Remove front coil spring *(see "Front Spring Replacement" above),* then remove lower control arm assembly from frame crossmember.

Lower Control Arm Shaft & Bushing Replacement - Unscrew bushings and remove from control arm. Check distance between inner ends of control arm. The normal distance is 11¼" ± 1/32", from inside to inside. Install rubber seal over each threaded end of new control arm shaft, with the large or bell ends of seals outward toward ends of shaft. Insert one end of shaft (with seal in place) in one control arm end and force opposite end of shaft into other control arm end, using a piece of wood as a pry bar. Fasten control arm securely in vise close to one end to prevent springing or distortion. Apply a liberal amount of Lubriplate or white lead to both bushings, then start first bushing in shaft and into control arm at the same time. Turn bushing until head is tight against arm and tighten to a minimum of 150 ft. lbs. Center shaft between arms and install second bushing, turning shaft as required to thread into the bushing so that no binding exists. Rotate shaft to locate bolt holes at both ends so they are equally distant from inside surface of arms.

1957 BUICK FRONT SUSPENSION ASSEMBLY

Installation: Place lower control arm assembly in position on frame crossmember and bolt in place. Tighten bolts to 70-80 ft. lbs. *(NOTE - Two different type bolts have been used at this location. See "Changes, Cautions, Corrections" above).* Install front spring and other parts. Check and adjust caster, camber, and toe-in.

►*1957 NOTE: Two different type bolts have been used at this location. See "Changes, Cautions, Corrections" ab ve.*

1958 MODELS

FRONT COIL SPRING: R m val - *(NOTE - For r m val f fr nt air spring, s Buick Air Suspension).* Raise car and support at all four corners of frame. Disconnect stabilizer link and shock absorber at lower end, then remove cotter pin and loosen nut on lower ball joint stud. With car supported by frame, place jack under outer edge of spring seat Wrap a chain around upper control arm and under base of jack and fasten chain securely. Raise jack to place tension on lower ball joint stud. Rap steering knuckle in area of stud to separate stud from knuckle. Lower jack slightly and remove stud nut and chain. *NOTE* - Interference may exist between nut and backing plate. After nut partially removed, raise jack slightly or move knuckle in relation to lower control arm to provide clearance. Raise jack and separate stud from knuckle. Lift knuckle, hub and drum assembly and support in raised position by placing suitable prop between upper control arm and frame. Lower jack carefully and remove coil spring.

Installati n: Tape rubber cushion to top of spring. *(NOTE* - On power steering models a shim is used at top of left hand spring). Position spring correctly

CONTINUED ON NEXT PAGE

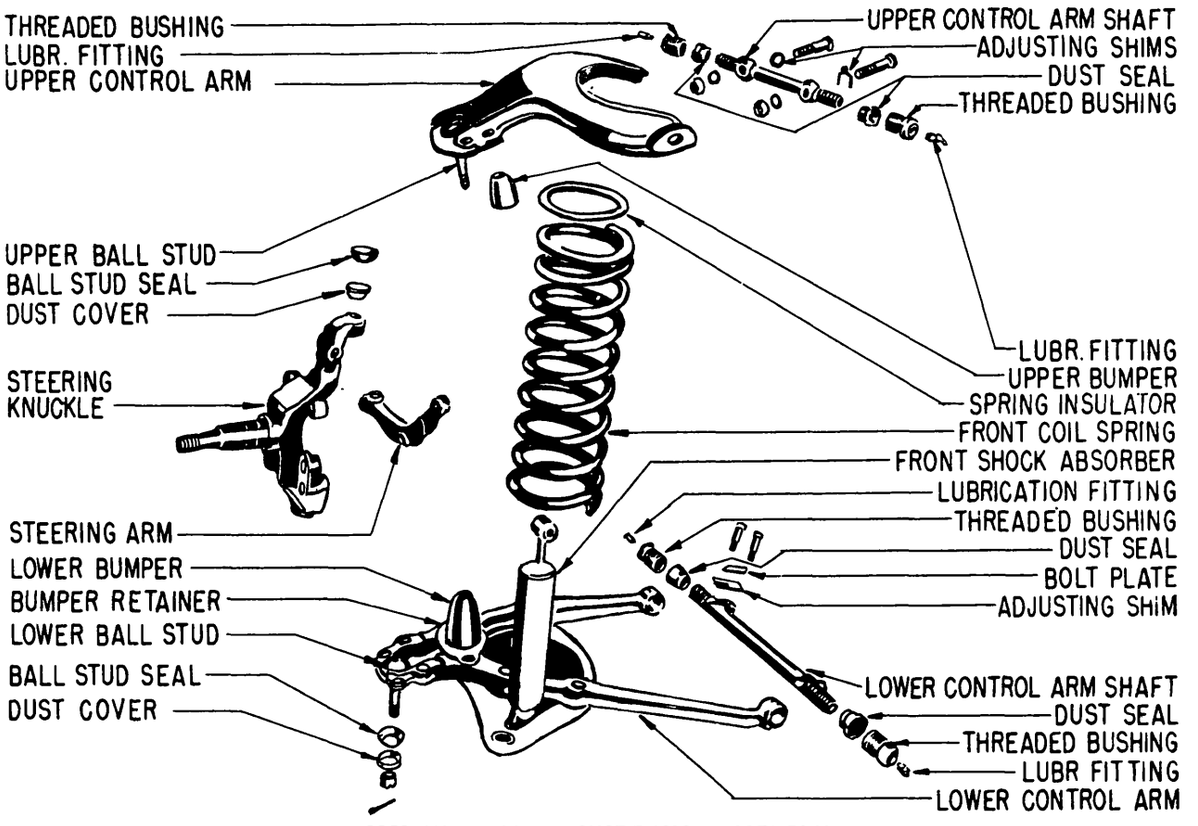
1957-58 BUICK FRONT SUSPENSION (C ntinued)

in frame crossmember and raise lower control arm to contact spring. Rotate spring if necessary to locate end of spring in drain hole of spring seat, then wire spring in spring seat. Raise lower control arm with jack placed under outer edge of spring seat. Remove prop under upper control arm and lower steering knuckle. Wipe stud and hole in knuckle clean, then assemble stamped and plastic dust shields on stud and start stud into knuckle hole. Before inserting stud completely, turn cotter pin hole fore and aft and start nut on stud. Tighten nut to 60-70 ft. lbs. and install cotter pin. Install grommets, retainers and nuts on lower end of shock absorber and stabilizer link. Reinstall wheel and tire and remove frame supports.

1958 Fr nt Spring Application

S ri s	Standard	Air Ci nd.
40 (Std. Trans)	1181626	1181627
40 & 60 (Auto. Trans.)	1181627	1181628
50, 70, 700	1181628	1174153

SHOCK ABSORBERS: *(CAUTION - Rear shock absorbers for cars with air susp nsion are not interchangeable with shocks for cars with conventional coil springs).*



R m val: Remove upper and lower mounting stem nuts, grommets, and retainers. Compress shock and disengage from mounting bracket and spring seat extension. Remove remaining grommets and retainer.

Installati n: Reverse removal procedure.

►*1958 SHOCK ABSORBER APPLICATION: See "Shock Abs rb rs" on Car Mod l page.*

STABILIZER LINK GROMMET REPLACEMENT: Remove nut from lower end of link rod, then remove rod, spacer, retainer and grommets. When assembling, install rubber grommets dry and use care to center grommets in seats on stabilizer shaft and lower control arm. Also center retainers on grommets before tightening rod nut. Tighten rod nut to limit of thread on rod. When rod nut is tightened to limit of thread on rod, the overall dimension between both grommet retainers should be 1 11/16". If this dimension is not correct, adjust nut as necessary.

BALL JOINT (AND STEERING KNUCKLE): Upper Ball J int R m val - Raise car with jack under frame (on air suspension cars, place in manual override position and support car at frame in rear and at frame front on side opposite from that being worked on). Remove wheel and tire. Remove cotter pin from nut on upper tapered stud, then loosen nut (but do not remove). Force of chassis spring will tend to disengage tapered stud from steering knuckle. Rap knuckle sharply in area of tapered stud to disengage from knuckle. On air suspension cars, return control to normal ride position). On coil spring cars, support car weight under outer edge of spring seat and remove nut from ball joint stud. On cars with air suspension, support car weight on frame and also place jack under spring seat. Support car weight on frame and lower jack under spring seat slightly. Be careful not to damage brake hose. Raise upper control arm and remove rubber bumper under upper control arm. Center punch the four rivets as close to center as possible, then drill a 1/8" hole through center of rivets. Drill a 1/4" hole more than half-way but not all the way through each rivet. Use a 1/2" drill or chisel to remove rivet heads. Drive rivets out with a 1/4" punch.

1958 BUICK FRONT SUSPENSION ASSEMBLY

Upper Ball Joint Installation: Assemble new ball joint to upper control arm with 5/16" bolts inserted from bottom (nuts and lockwashers on top), and tighten nuts to 15-20 ft. lbs. Reinstall rubber bumper. Turn tapered stud so cotter pin hole is fore and aft and assemble stamped and plastic dust shields over stud. Move knuckle up by jacking under outer edge of spring seat. Wipe tapered hole in knuckle and tapered stud clean and assemble stud to knuckle with castellated nut. Tighten to 30-40 ft. lbs. and install cotter pin. On air suspension cars, set in manual override position and operate engine until override position is reached. Reinstall wheel and tire and remove frame support.

Lower Ball Joint Removal: Raise car and remove wheel and tire. On cars with air suspension, place in override position and support frame of car at all four corners. Disconnect stabilizer link and shock absorber at lower end, then remove cotter pin and loosen nut (do not remove) on lower ball joint stud. With car supported at frame, place jack under outer edge of spring seat Wrap a chain around upper control arm and under base of jack, then fasten chain securely. Raise jack to place tension on lower ball joint stud. Rap steering knuckle in area of stud to separate knuckle from stud. Lower jack slightly, then remove nut and chain. *NOTE* - Interference may exist between nut and backing plate. After partially removed, raise jack slightly or move knuckle in relation to lower control arm to provide clearance. On air suspension cars, return control to normal ride position. Raise jack and separate stud from knuckle, then raise knuckle assembly and support in raised position by placing prop under upper control arm. Lower jack carefully (on cars with air suspension, remove spring nut at bottom of plunger bearing to allow lower control arm to be lowered leaving air spring attached to frame). Remove front chassis spring if coil spring equipped. With outer end of lower control arm resting on floor and car supported in a safe manner, center punch the four 3/8" rivets and drill a 1/8" hole through each rivet, Drill a 5/16" hole more than half-way through each rivet (not all the way through), then use a 5/16" punch to drive rivets out.

L w r Ball J int Installation: Install a new ball joint using 3/8" bolts (longer bolts at inner location). Assemble bolts with head down and tighten nuts to 35-40

CONTINUED ON NEXT PAGE

1957-58 BUICK FRONT SUSPENSION (Continued)

ft lbs On coil spring cars, tape rubber cushion to top of spring (on cars with power steering, a 1/8" steel shim is used at top of left hand coil spring) On air suspension cars, locate plunger pilot and bearing in socket If equipped with coil spring, position spring correctly in frame crossmember and raise lower control arm to contact spring Rotate spring if necessary to locate end of spring in drain hole of spring seat Wire spring in spring seat, then raise lower control arm with a jack placed under outer edge of spring seat Remove prop under upper control arm, then lower steering knuckle Wipe stud and hole in knuckle clean, then assemble stamped and plastic dust shields on stud and start stud into knuckle hole Before inserting stud completely, turn cotter pin hole fore and aft and start nut on stud Tighten castellated nut to 60-70 ft lbs and install cotter pin Reassemble grommets, retainers, and nuts on lower end of shock absorber and stabilizer link, and on cars with air suspension reinstall spring nut on plunger bearing On air suspension cars place in manual override position then operate engine until override position is reached Reinstall wheel and tire and remove frame support

UPPER CONTROL ARM: *NOTE Upper control arms are not furnished separately, their replacement must be made as an assembly.*

Removal: Separate upper ball joint from knuckle (see above), then remove shaft to frame bracket nuts, carefully noting number, location, and thickness of shims between shaft and frame bracket Remove arm assembly

NOTE - On right side of car, it will be necessary to remove generator and bracket On left side of car, remove negative battery cable

Upper Control Arm Shaft & Bushing Replacement Clamp arm assembly in vise and remove old bushings and shaft Assemble new grease seals on shaft and position shaft in arm Start new bushing in original threads of arm and thread shaft into bushing to aid in alignment Tighten bushing to 70-75 ft lbs Start second bushing into original threads of arm with shaft threaded into opposite bushing After bushing has been threaded part way into arm, rotate shaft to engage threads of second bushing as an aid to piloting bushing squarely into position Tighten bushing to 70-75 ft lbs (shaft should be free enough to turn by hand) Install grease fittings and lubricate bushings Rotate shaft so distance between shaft bolt holes and arms is equal on both sides

Installation: Reverse removal procedure being careful to locate steel washers under heads of shaft-to-frame bolts Install same number and thickness of adjusting shims in correct location as noted at removal, between shaft and frame bracket Tighten shaft-to-frame bracket bolts to 90-100 ft lbs

LOWER CONTROL ARM: *NOTE - Riveted parts of lower control arm assembly are not furnished separately.*

Removal: Remove front coil spring *(see "Front Spring Replacement" above)*, then remove lower control arm assembly from frame crossmember.

Lower Control Arm Shaft & Bushing Replacement - Unscrew bushings and remove from control arm. Check distance between inner ends of control arm The normal distance is 11¼" ± 1/32", from inside to inside. Install rubber seal over each threaded end of new control arm shaft, with the large or bell ends of seals outward toward ends of shaft. Insert one end of shaft (with seal in place) in one control arm end and force opposite end of shaft into other control arm end, using a piece of wood as a pry bar. Fasten control arm securely in vise close to one end to prevent springing or distortion. Apply a liberal amount of Lubriplate or white lead to both bushings, then start first bushing in shaft and into control arm at the same time. Turn bushing until head is tight against arm and tighten to a minimum of 150 ft. lbs. Center shaft between arms and install second bushing, turning shaft as required to thread into the bushing so that no binding exists. Rotate shaft to locate bolt holes at both ends so they are equally distant from inside surface of arms.

Installation: Place lower control arm assembly in position on frame crossmember and bolt in place. Tighten bolts to 70-80 ft lbs Install front springs and other parts Check and adjust camber, caster, and toe-in

1959-60 BUICK FRONT SUSPENSION

All Series (1959-60)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*LOWER BALL JOINT LOOSENESS NOTE:* With car jacked up (no load on front wheels), lower ball joint is loose and no corrective measures should be taken unless the looseness, measured at outer circumference of tire, is greater than ¼" laterally If movement of front wheel exceeds ¼", replace lower ball joint

DESCRIPTION: "Ball Joint" type suspension with ball and socket joints connecting upper and lower control arms to steering knuckles Coil springs or air springs are mounted between lower control arms and frame front crossmember and the shock absorbers are mounted within the front coil springs on lower control arm and attached to brackets on frame front crossmember Control arm shafts are bolted to frame crossmember and are connected to control arms by threaded type bushings.

ADJUSTMENT

CHECKING & ADJUSTING: Before checking or adjusting front suspension alignment, inflate tires to specified pressure. Check front wheel bearings for looseness and correct as necessary. Check for runout of wheels and tires and correct to within limit of 1/8" runout at side of tires Check for looseness at upper ball joints and tie rod ends and correct if found excessive Bring car to height specified below

▷*CAMBER & CASTER ALIGNMENT NOTE (CARS WITH COIL SPRINGS):* Place a piece of ¾" pipe 4 15/16" long between frame and lower control arm at each front wheel (see illustration) Place pipe over the front outer spring seat rivet and make sure it is vertical Use sandbags or other suitable weights when necessary to hold car down on pipes Bring rear of car to proper height If gas tank is full and the trunk empty except for spare tire and jack on a coil spring car, the rear of the car may be considered at the proper height If these conditions cannot be met, a ¾" pipe, 6¾" long (1959), 6 13/16" long (1960) should be placed between axle housing and axle bumper stop (see illustration) Use sandbag or suitable weight to hold car down on pipe

▷*FRONT END ALIGNMENT NOTE (CARS WITH AIR SUSPENSION):* Check distance between lower side of frame side rail, immediately forward of the air spring (rear end of bumper if car is so equipped) This distance should be 5¾"±¼" (Exc Sta Wagon), 5 13/64"± ¼" (Sta Wagon) *NOTE – Car should be loaded slightly and allowed to lift slowly so as to measure trim height at the bottom of height valve "dead spot"*

Tire Inflation: 24 lbs. (Starting pressure) after car has been standing for three hours or driven less than one mile (28 lbs on Station Wagon rear tires) 26 lbs. (city pressure) after car has been driven three miles or more below 40 MPH (30 lbs on Station Wagon rear tires) 28 lbs. (highway pressure) after car has been driven three miles above 40 MPH (32 lbs on Station Wagon rear tires)

Steering Axis Inclination: 7° at ¾° camber No adjustment

▷*CAMBER & CASTER ADJUSTMENT CAUTION Both camber & caster are adjusted by shimming in the same locations, therefore both should be checked before changing either setting.*

▷*CONTROL ARM SHIMMING NOTE (FOR CAMBER & CASTER ADJUSTMENT):* If only a small adjustment is required to bring alignment within limits, make shim adjustments at lower control arm If the amount of shims exceed 160" in any one stack on lower control arms, make adjustments at the upper control arm shafts Under no circumstances should total shim thickness exceed 160" on lower control arm shafts, and .380" on upper control arm shafts Replace necessary parts if proper alignment cannot be obtained within these limits

Caster: Neg 2° ± ¾° Both sides should be within ¾° of each other *See "Shimming Procedure" below*

Camber: Pos 1° to Neg ½° (Pos ½° desired) Both wheels should be within ¾° of each other *See "Shimming Procedure" below*

Toe-In: 1/16" to 5/32" *CAUTION – Car must be at curb weight and running height (bounce car and allow it to settle to running position DO NOT ALLOW ALIGNMENT PINS (see above) TO REMAIN IN POSITION WHILE CHECKING OR ADJUSTING TOE-IN* Loosen clamp bolts and turn adjusting sleeves at tie rod end as required Turn right and left adjusting sleeves exactly the same amount but in opposite directions when changing toe-in, in order to maintain front wheels in straight ahead position when steering wheel spoke is straight down. Position tie rod clamps downward to 45° forward

CONTINUED ON NEXT PAGE

1959-60 BUICK FRONT SUSPENSION (C ntinu d)

to provide frame clearance. *NOTE - It is very important to position bottom face of tie rod end parallel with machined surface at out r end of steering arm when tie rod length is adjusted.*

T e-Out n Turns: With outer wheel turned 20°, inner wheel should be 23° (Manual Steering), 22° (Power Steering). Not adjustable.

Shimming Procedure: *NOTE - No lower control arm shims ar installed in production, however, it is recommended that all shimming required for service adjustments be done at low r control arm shaft providing shim stacks at any one location do not exceed .160". If in excess of this thickness, adjustment must be made at upper control arm shaft D not exceed 380" in any one stack at upper control arm*

Shim Selection (For installation at both upper and lower contr l arms) - *(NOTE - Upper and lower control arm shaft shims are different and are furnished in sizes indicated in table below).* Adding shims at front location will change **cast r t ward negative** (Practically no change in camber or toe). Adding shims at rear location will change **cast r toward positive** and camber toward negative (toe toward toe-out). Adding shims at both locations will **n t change caster,** but will change **camber t ward negativ**

►*SHIMMING AT LOWER CONTROL ARM NOTE:* If shims are added at lower control arm, replace original lower control arm shaft bolts with 300M bolts (½" – 20x 2 1/8"), Part No. 427576. Tighten bolts to 105–120 ft. lbs.

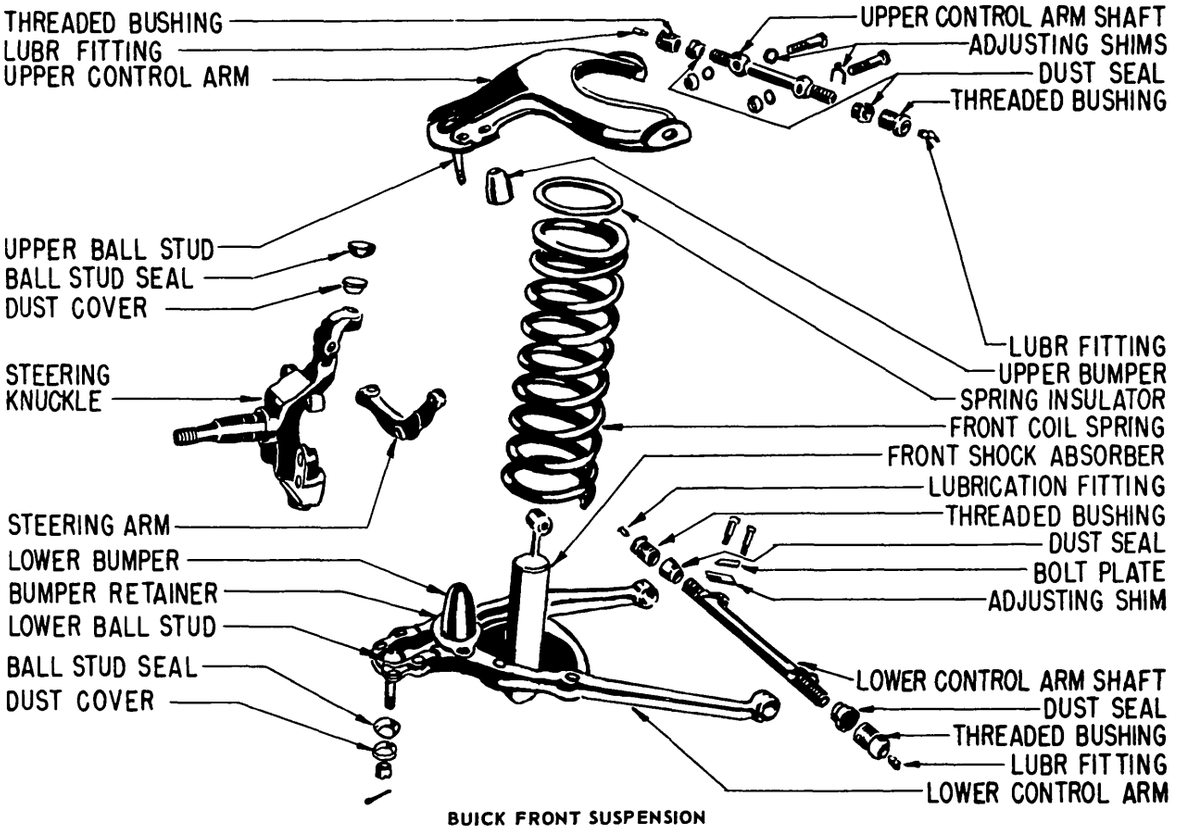
►*SHIMMING AT UPPER CONTROL ARM NOTE:* On right side of car, remove generator belt tensioning bracket. On left side of car, disconnect battery ground strap. Tighten control arm-to-frame bolts to 90–100 ft. lbs.

1959 L w r Control Arm Shaft Shims

Thickn ss	Part No.
040"	1180938
120"	1180939

1960 L wer C ntrol Arm Shaft Shims

Thickn ss	Part No.
.040"	1194541
.100"	1194542



1959-60 Upp r Control Arm Shaft Shims

Thickn ss	Typ ①	Identification ②	Part No.
.060"	Horseshoe	6	1171175
.080"	Horseshoe	8	1172986
.100"	Horseshoe	10	1175585

① - Furnished with either "horseshoe slot" or round hole.
② - Identification number stamped on shim.

Shim Installati n (L wer Control Arm) - To prevent movement of lower control arm shaft on frame member during shim installation, loosen only one bolt at a time. Install shim and tighten bolt before installing shim at opposite end Tighten bolts to 105-120 ft lbs

Shim Installati n (Upp r C ntrol Arm) – On left side, disconnect battery ground strap from battery. On right side, remove generator belt tensioning bracket. Wedge bolt heads of all upper control arm shaft bolts to prevent turning, then loosen both bolts on each shaft to free shims for removal. Tighten bolts to 90–100 ft. lbs.

BUICK FRONT SUSPENSION

Trim Dimensions Adjustment (Front): *(NOTE - The following dimensions are for a standard car without undercoating or optional equipment and with the car at curb weight. Curb Weight includes gas, oil, and spare tire, but no passengers).* Before measuring trim dimensions, bounce both ends of car up and down several times to make sure there is no bind in suspension members and to let springs take natural position. When car is at rest, measure trim height between front arm of lower control arm assembly and frame crossmember at a point between rubber bumper and spring. Measurement must be made as vertical as possible. See table below for trim heights. When trim dimension is found to be too low, install special 1/8" shims between upper end of spring and frame. *NOTE – If more than three shims required, replace spring.*

►*FRONT SPRING SHIM NOTE (CAR WITH POWER STEERING):* One spring shim is installed on top of left spring on these cars None installed on right side in production.

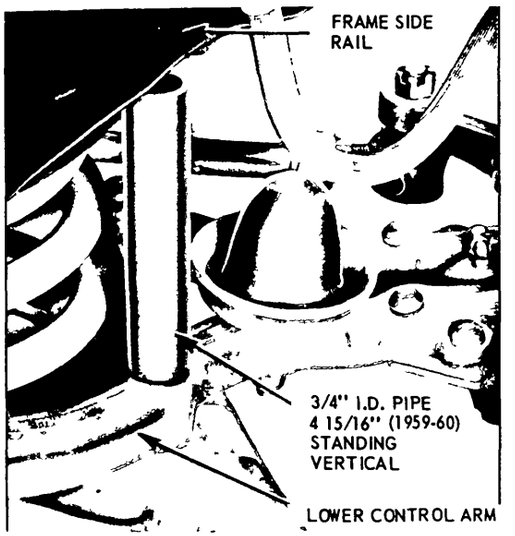
►*1960 SPRING IDENTIFICATION NOTE:* Springs are identified by a dab of paint as follows: Red (1192425); Orange (1192426); Light Blue (1192427); Light Green (1192428).

SHOCK ABSORBER: Removal – With front of car raised, remove upper mounting stem nut, grommet retainer and grommet. *NOTE – ¼" flat on shock absorber stem may be used to hold stem while removing nut.* Remove two lower mounting bracket-to-spring seat bolts and lower shock absorber through spring seat.



Installation: Reverse removal procedures.

►*SHOCK ABSORBER APPLICATION:* S "Shock Absorbers" n Car Mod l pages.

►*1959 BUICK UPPER CONTROL ARM & BALL JOINT PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A new coil spring preloaded ball joint, Part. No. 1388924, is being used in production and for service replacement on later cars. The upper control arm has also been changed to accomodate the new ball joint which is bolted to the control arm (previous ball joints were riveted to control arm). The new joint is not interchangeable with previous type, however, the previous type may be used for service replacement.

REAR HEIGHT ALIGNMENT SPACERS

FRONT HEIGHT ALIGNMENT SPACERS

All Series (1954-57)

DESCRIPTION: Coil spring type.

TRIM DIMENSION: Before measuring rear spring trim dimension, bounce car up and down several times to make certain that suspension is not binding and to allow springs to assume natural position and proceed as follows: Measure distance from top of axle housing to top of bumper clip on frame side rail to rear of bumper 1954-55), from pivot bolt to raised portion on forward end of bumper bracket (1956-57) If trim dimension not correct with car at curb weight, replace springs

TRIM DIMENSIONS

1954 Models	Height
46C, 56C, 76C, 100	5¼-6"
All Other Models	5½-6¼"
1955-56 Models ①	**Height**
46C, 46R, 56C, 56R, 66C, 66R, 76C, 76R	4¼-5¼"
All Other Models	5½-6¼"
1957 Models ①	**Height**
46C, 46R, 56C, 56R, 66C, 66R, 76C, 76R	4 5/8-5 5/8"
48, 49, 69	5 1/2-6 1/2"
All Other Models	5 1/8-6"

REAR AXLE RADIUS ROD: Radius rod need not be removed for rear axle removal (disconnect rod at right hand end) but should be removed and checked for straightness and twist when new bushings installed.

Removal—Support rear end of car on jacks under axle housing so that weight of car is on springs. Take off nuts and washers on radius rod pins (at each end of rod), remove pin support at right end and frame bracket brace (pin support on 40 series) at left end of rod. Remove rod and bushings from pin on frame bracket.

1954-57 BUICK REAR SUSPENSION

Installation—Reverse removal procedure, using new rubber bushings. **Car weight must be on rear springs when tightening pin nuts** (to insure that rubber bushings will be clamped in neutral position).

REAR AXLE STRUT ROD REPLACEMENT CAUTION: Replacement torque tubes are furnished without holes drilled for strut rod rivets in the mounting bracket. Drill these holes only after rear axle housing, torque tube, and strut rods have been assembled. With strut rods in normal position (without up or down strain), drill bracket to match holes in strut rod with ½" drill, then drill through strut rods and bracket with 9/16" drill, install No. 1312923 bolts with lockwashers and thin nuts.

SPRING SPECIFICATIONS: Special 200 lb. and 500 lb. Overload Rear Springs are available for use with trailers or when heavy loads carried in car.

1958-60 BUICK REAR SUSPENSION

All Series (1958-60)

►*1958 REAR SPRING PRODUCTION CHANGE (SERIES 40, 50, 60, 70 4-DOOR SEDAN MODELS).* To increase rear wheel travel and prevent bottoming, rear springs, Part No 1175992 (Series 40 & 60), Part No 1175995 (Series 50 & 70) have been replaced in production with Part No 1185351 (Series 40 & 60), Part No 1182896 (Series 50 & 70) Should improper trim height be encountered on the above early production cars, install one additional insulator, Part No 1172761 over each rear spring

DESCRIPTION: Rear wheels are held in proper alignment by rear axle housing and by torque tube and radius rods between car frame and rear axle assembly Side sway of chassis springs and rear end of frame is prevented by a transverse radius rod Coil type springs, or air springs, are mounted between frame crossmember at top of kickup and spring seats (for coil springs) or a special bracket (for air springs) welded to axle housing Direct acting shock absorbers are angle mounted between axle housing and rear spring crossmember

REAR COIL SPRING: Removal - *(NOTE - For removal of rear air springs, see "Buick Air Suspension")* Raise car and support frame, then disconnect both rear shock absorbers at lower end Remove upper and lower spring clamps and remove spring

Installation: Make sure that spring insulator at upper end is in good condition, then attach upper end of spring using spring clamp, bolt insulator, flat washer, lock washer and nut Attach lower end of spring to axle housing bracket with spring clamp Lower car and attach shock absorbers with normal car weight on rear wheels

Trim Height Adjustment: *(NOTE - The following dimensions are for a standard car without undercoating or optional equipment and with car at curb weight Curb weight includes gas, oil, and spare tire, but no passengers)* Before measuring spring trim dimensions, bounce both ends of car up and down several times to make sure there is no bind in suspension members, and to let springs take natural position When car is at rest, measure trim height between top of axle housing and flange of rubber bumper (see illustration) See table below for trim height limits If rear spring trim dimension is less than specified, or additional height is required to prevent excessive bottoming install additional spring insulators, divided between upper and lower ends of spring If more than three additional insulators are required, replace the spring *NOTE* - Installation of a new spring should not increase spring trim dimension more than 1" over specified limits

200 Lb. Overload Spring - Spring No. 1193935 (4700 series), 1193935 (4800 Convertible), 1193936 (All others).

500 Lb. Overload Spring - Spring No. 1188960 (4700 Series 2-Dr.), 1188960 (4800 Convertible), 1193934 (All others).

►*NOTE: Overload springs are not available for station wagon models.*

►*SHOCK ABSORBER APPLICATION* See *"Shock Absorbers" on Car Model pages and note the following* Shocks on air suspension cars have an extended length 1" shorter than for standard suspension cars Do not use standard suspension shock absorbers on air suspension cars

Track Bar Bushing Installation (1959-60) Raise car and support axle housing so weight of car will be on rear springs. On right side of car, remove three track bar support to frame bolts and remove track bar pivot bolt, then remove support. At left side, remove track bar pivot bolt, then remove track bar. Press out old bushing using an arbor press, then press in new bushing until flange is in contact with eye of track bar. *NOTE - Bushings may be pressed into track bar from either direction, however, both bushings should be pressed in from the same side.* To install track bar, slip it into axle bracket and install the bolt but do not tighten it. *NOTE - Track bar bracket bolts must not be tightened unless car is at normal trim height.* Position track bar against frame bracket and install three support bolts and track bar pivot bolt loosely. Tighten track bar pivot bolt to 90-105 ft. lbs. Tighten support bolts to 15-25 ft. lbs. Tighten axle end track bar pivot bolt to 90-105 ft. lbs.

1954-56 CADILLAC FRONT SUSPENSION

All Series (1954-56)

►CHANGES, CAUTIONS, CORRECTIONS

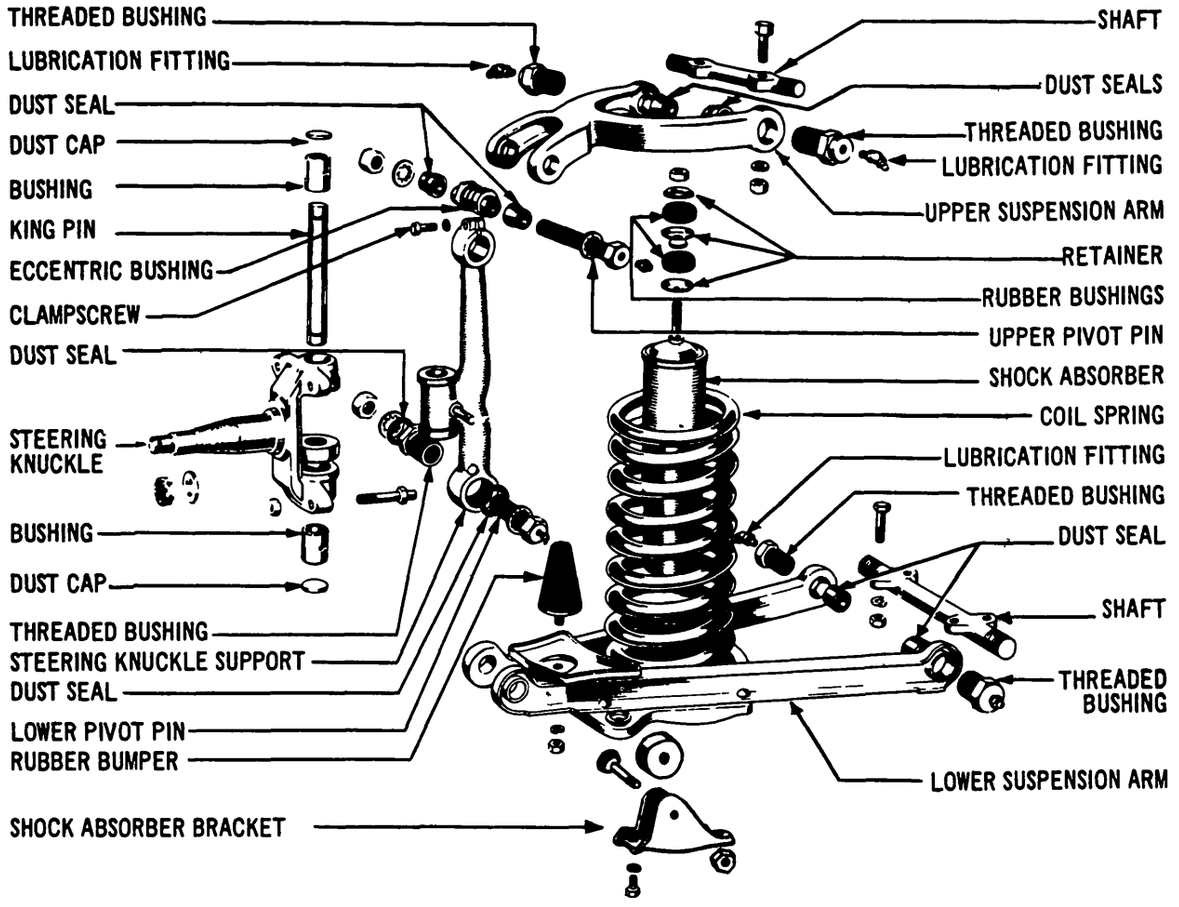
►*1954 DRAG LINK TO TIE ROD INTERFERENCE CORRECTION:* This interference is on the right side and is generally caused by the idler arm being too high. Correct by loosening the idler arm support-to-frame screws and rotate the idler arm down and forward as far as possible, then tighten screws. In addition, the idler arm should be backed out of its bushing in the support a total of 2½ turns.

►*1954 COMMERCIAL CHASSIS FRONT WHEEL RUBBING FENDER CORRECTION (On Extreme Right or Left Turns):* Check the special steering arm-to-knuckle screw which incorporates the wheel stop. A 1/16" washer should be between the head of the screw and the steering knuckle. If this washer in place, the trouble lies in excessive weight on the front springs and can be corrected by installing front spring shims, Part No. 1457838 on TOP of each spring, or installing heavy duty front springs. To determine if heavy duty springs are required, proceed as follows: Weigh front end of car (with total load carried at time of complaint, and with vehicle level). If weight exceeds 3200 lbs., heavy duty springs are indicated. These springs, Part No. 1460998 are available for service replacement. *NOTE —Heavy duty Rear Springs, Part No. 1460931 are also available if rear end weight exceeds 3900 lbs.*

►*1954 KINGPIN LUBRICATION FITTING INTERFERENCE CORRECTION (Fitting Strikes Steering Knuckle Support and is Damaged):* If difficulty is encountered getting grease through this fitting, remove the fitting and counterbore the original tapped hole to a depth of 3/32"-1/8", using a ½" drill ground at 140° included angle. Run a ¼"-28 tap through to clean the threads, then install a new fitting.

►*1955 FRONT WHEEL BEARING NOISE CORRECTION:* On cars between Engine No. 33512 and 34344, there is the possibility that oversize bearing cones were installed. Check bearing cone to shaft clearance as the oversize cone will have in excess of 1/32" clearance.

►*1955 EL DORADO FRONT & REAR SPRING PRODUCTION CHANGE:* At Engine No. 41150 the overall height of the Eldorado has been lowered 1" by the use of different springs, as follows: No. 1461008 (Front), No. 1460932 (Rear).



►*1955 STABILIZER LINK PRODUCTION CHANGE & INSTALLATION CAUTION:* At Engine No. 70000, a shorter link (6⅜"), and spacer (2½") replaced the early link (7"), and spacer (3⅛"). Either the short or long link may be used but it is important that links on both ends of the front stabilizer be of the same length.

►*1955 FRONT COIL SPRING PRODUCTION CHANGE:* Later cars do not have a spring lower insulator and the front springs have been increased slightly in length. When installing the later type front spring, the lower insulator should be discarded.

►*FRONT SPRING NOISE CORRECTION:* If click, scrape or grind noted (particularly on low speed brake application) correct as follows:

Seating Spring in Upper Seat—Drive car at moderate speed and apply brakes sharply (will cause spring to center itself in upper seat) or use pry bar to push upper end of spring onto its seat.

Insufficient Clearance at Lower Cross-Member flanged opening—After spring seated properly, check clearance between spring and lip of flanged opening in lower cross-member. Correct by bending lip on flange (CAUTION—do not use heat and bend lip only in area where contact occurs).

CADILLAC FRONT SUSPENSION

DESCRIPTION: New design independent "parallelogram" type with coil springs and direct acting shock absorbers mounted independently of upper control arm. Upper control arm is new design mounted on frame bracket shaft in same manner as lower control arm. Shock absorbers can be removed and installed without disturbing upper control arm assembly.

ADJUSTMENT: Before making adjustments, check tire pressures (see data below), front wheel bearing adjustment, check for run-out and high spots (3/64" maximum in each case), wheel and tire balance, and spring height. Make certain that entire suspension system operates freely without binding or excessive play, place wheels in straight-ahead position and see that car is at curb weight. Then check and adjust following points in order:

Tire Inflation—(60S, 61, 62) 24 lbs. front and rear, (75) 28 lbs. front and rear, (86 Comm'l) 24 lbs. front, 30 lbs. rear.

Front Spring Height—See that car is at curb weight (full tank of gasoline, no load in trunk or car), normalize spring position by working bumper up and down and release slowly so that car assumes normal position. Then check distance from center of front lower rivet on rubber bumper bracket on frame to top surface of lower control arm spring seat directly below this rivet. Correct heights are listed in table below and should be equal on both sides of car within ⅜". Correct height by installing shim between bottom of spring and spring seat on low side of car or replace springs. See Spring data.

►*CAUTION—Do not replace springs to correct excessive height during first 2000 miles (springs settle considerably during this period).*

CONTINUED ON NEXT PAGE

1954-56 CADILLAC (C nt.)

1954-55 Front Spring Heights

Car Mod l	Spring Height
All Models (Exc. 75 & 85)	4½-5¼"

All Models (Exc. 86)	8 3/4-9 1/2'
86 (Commercial)	10 1/4-11'

Front Wheel Run-out—Mark point of maximum run-out on tire, turn wheel so that this mark is at front or rear when checking Caster and Camber, at top or bottom when checking Toe-In and Toe-Out.

Kingpin Inclination: 5°51' crosswise, all models.

Caster: 0° to Neg 1° Must be equal on both sides of car within ½°

Adjustment—Loosen clampscrew in upper end of knuckle support, use special wrench, Adjusting Tool KMO-366 or J-4691 (see Tool Note), to turn eccentric bushing on pivot pin. (NOTE—hexagonal head on bushing for wrench engagement located at rear end of bushing on early 1950 cars, front end on later cars). Turn eccentric bushing in complete turns only until correct caster secured, tighten clampscrew.

►**Adjusting Tool Note**—KMO-366 is special thin open-end wrench, J-4691 is special "crow-foot" wrench with square drive opening and can be used on all cars (regardless of bushing head location).

►***CAUTION—Camber will be disturbed unless bushing rotated in complete turns only.***

►***ADDITIONAL RANGE OF ADJUSTMENT***—If correct caster cannot be secured within limits of eccentric bushing rotation, additional range of adjustment can be secured by disconnecting lower support arm inner mounting shaft at frame cross-member and turning shaft in the arm (moving shaft to rear will increase positiv caster).

Camber: 0°±3/8° (Neg 3/8° to Pos. 3/8°) 0° preferred Variation limit between right and left wheels ½°. NOTE - ¼° to ½° more camber (1956) on left wheel on high crowned roads.

Adjustment—Same as for Caster (above). Turn eccentric bushing not more than ½ turn in either direction from point where correct caster is secured.

►***CAUTION—Entire range of camber adjustment secured in ½ turn of the eccentric bushing.***

Toe-In: 3/16-1/4" (1954-55), 5/32-7/32" (1956) Check with wheels in straight ahead position and point of maximum wheel "run-out" vertical

Adjustment—Loosen clampscrews and turn Adjuster at outer end of each tie-rod equally (turning adjuster in direction of forward wheel rotation will decrease toe-in). Tighten clampscrews.

►***CAUTION—Open side of adjuster clamps must be over open side of adjuster when clampscrews tightened.***

Toe-Out on Turns: With outer wheel turned 20°. inner wheel should be turned as follows:

1954-56 Series (All) - With outer wheel turned 20°, inner wheel should be 22°40'.

SHOCK ABSORBER REPLACEMENT: ***Not necessary to disturb Front Suspension Assembly.*** **Remove upper retaining nut, retainer, and rubber grommet from upper spring seat tower in engine compartment (NOTE—use wrench on squared upper stem of shock absorber to prevent it turning while loosening nut). Remove two bolts retaining lower shock absorber bracket on lower face of spring seat on lower control arm, then withdraw shock absorber and bracket assembly through hole in spring seat. Remove lower bracket by taking off retaining nut, grommets and retainers from shock absorber stem.**

►**Installation Note**—See illustration for correct assembly of grommets and retainers on shock absorber stem. Use wrench on squared upper stem of shock absorber to prevent unit turning while tightening retaining nuts.

COIL SPRING REPLACEMENT: Support front end of car on jack under center of front cross-member, use second jack under suspension arm to support spring which is being removed. Disconnect front stabilizer link on same side of car. Remove shock absorber (see data above). Remove nut on lower pivot pin, unscrew pin from lower control arm and knuckle support. Lower jack under suspension arm until spring tension relieved, remove jack, lift spring out. Install spring by reversing this procedure.

►**Spring Installation Caution**—Install spring with open (tanged) end upward and seated in upper seat so that tang parallel with raised area on cross-member and visible through correct hole in the cross-member (right front spring tang visible through rear hole, left front spring tang visible through front hole). Hold spring in this position while raising lower suspension arm, drive or pry bottom of spring into its seat on lower arm (will not seat freely with arm lowered and spring fully extended).

FRONT STABILIZER REMOVAL & INSTALLATION: Disconnect link by removing nut on lower end and withdrawing link bolt from above (CAUTION—note location of retainers and grommets at upper and lower ends of link and replace in exact same order). Remove bolts from two frame mounting brackets, remove stabilizer. Remove rubber bushings from stabilizer brackets and bar (these bushings serviced separately). Install stabilizer by reversing above procedure.

SPRINGS: Part number is stamped on end coil and springs are color-marked for identification.

1954 Spring Specifications④

Car Model	Color Code	Part N .
6019①	Lt. Blue	1460194
6219, 37, & 37D①	Green	1460193
6267, 6267S①	Pink	1460195
6019, 6219, 37, & 37D②	Pink	1460195
7523, 7533①	Purple	1460191
7523, 7533②	Orange	1460192
86	None	③ 1460189

①—Without Air-Conditioning
②—With Air-Conditioning
③—See "FRONT WHEEL RUBBING CORRECTION" above for Heavy Duty Springs available

① - Spring part number is stamped on an end coil

►*1956 FRONT SPRING INSTALLATION NOTE* Lower insulator no longer used

1957-60 CADILLAC FRONT SUSPENSION

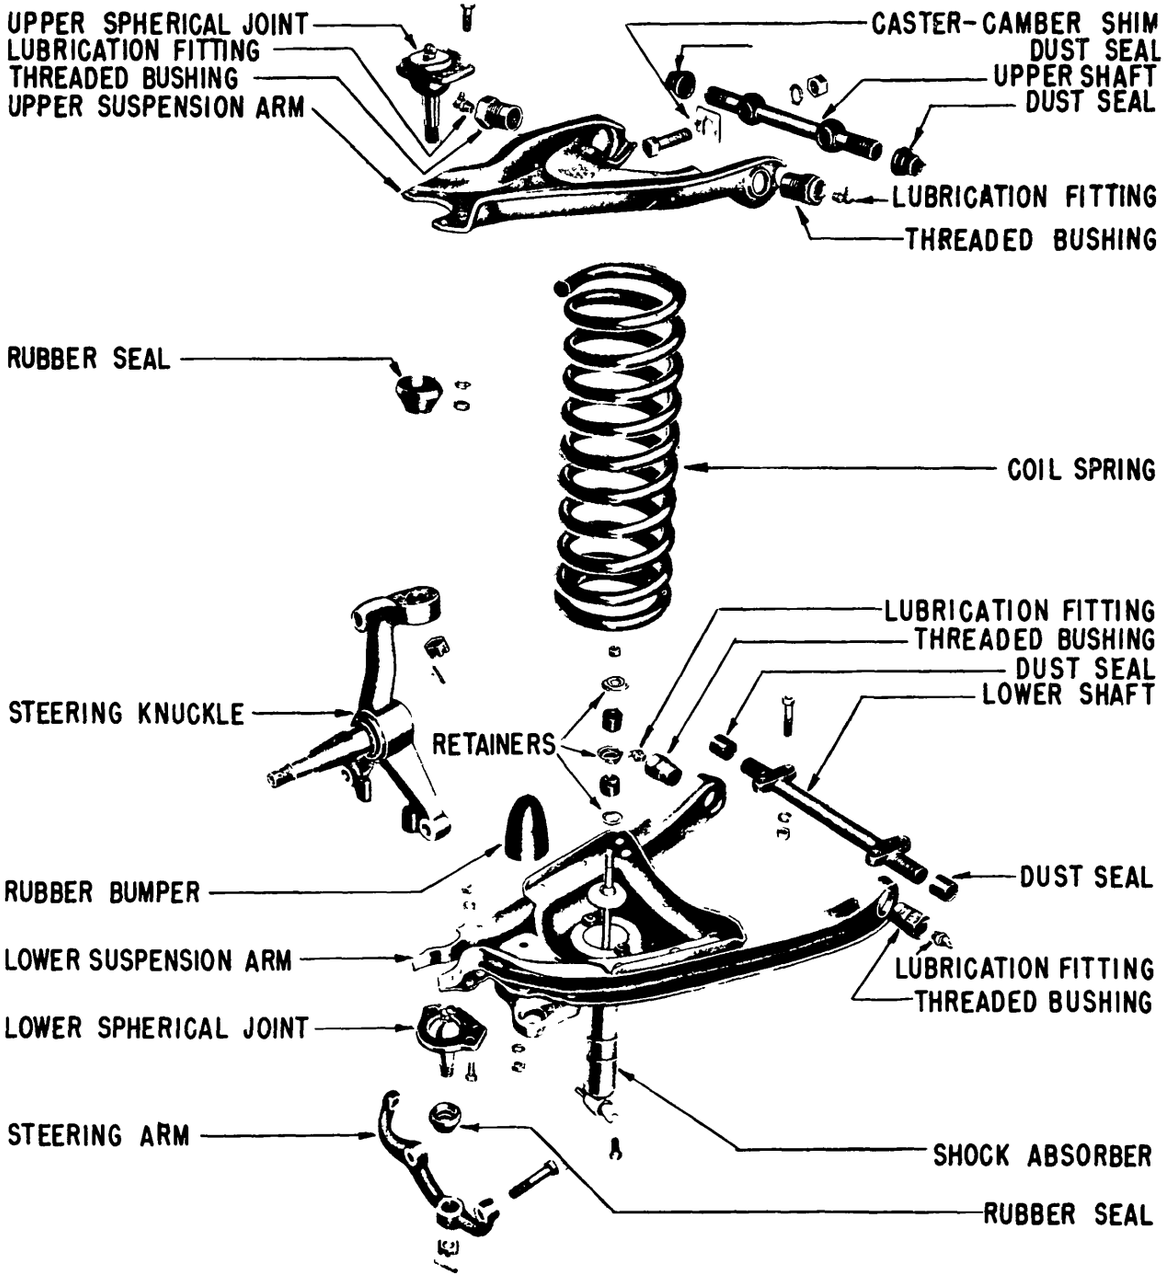
All Series (1957-60)

►*JACKING & HOISTING: See "Jacking & Hoisting Precautions".*

►*AIR SUSPENSION CAR NOTE:* Except where noted, front wheel alignment and front suspension linkage removal and installation is the same as for conventional cars. *See "Cadillac Eldorado Brougham Air Suspension" & "Cadillac Air Suspension", for air spring removal, installation and adjustment.*

►CHANGES, CAUTIONS, CORRECTIONS

►*1957 TIRES RUBBING ON STABILIZER BAR CORRECTION:* This condition occurs on sharp turns and can be corrected by installing Steering Knuckle Stop, Part No. 1468700. This "U" shaped stop is thicker than used in production and is attached to lower suspension arm by the rear outer spherical joint attaching bolt. If only one tire rubs on stabilizer bar, reposition stabilizer bar to center it on car before determining if thicker stops are necessary.



►*1957 DRAG LINK & TIE ROD PRODUCTION CHANGE TO IMPROVE STEERING GEOMETRY DURING BODY ROLL:* A new drag link and tie rod assembly is used in production beginning with Engine No. 023831. With this change, the clearance between frame and tie rod makes repositioning of tie rod sleeve clamps necessary which will eliminate the possibility of clamp interfering with frame when driving over severe bumps. On all cars above Engine No. 023831, the tie rod sleeve should be rotated so that openings in clamps are underneath the tie rod.

►*1957 LOWER CONTROL ARM MOUNTING BOLT PRODUCTION CHANGE:* Beginning with Engine No. 042036, mounting bolts, Part No. 1468512 having larger diameter heads are being used in production and for service replacement. When installing the later type bolt, the hardened steel flat washer formerly used should be discarded.

►*1960 UPPER & LOWER CONTROL ARM MOUNTING BOLT PRODUCTION CHANGE:* Beginning with Engine No. 020420, "Stover" type self-locking nuts are used on these bolts. Lockwashers have been eliminated. Upper control arms with this type self-locking nut, identified by a depressed section of two opposite "flats" of nuts, should be tightened to 65-85 ft. lbs. (supersedes previous limits of 130-140 ft. lbs.). The nuts on lower control arm mounting bolts are self-locking type of same design as upper control arm nuts (without lockwashers) and should be tightened to 60-70 ft. lbs. (same as previous tightening limits). *DO NOT OVERTIGHTEN bolts having this type nut.*

►*1960 TIE-ROD ADJUSTER CLAMP BOLT NUT TIGHTENING NOTE:* Later cars have the new "Nylok" type self-locking nuts on tie-rod clamp bolts which should be tightened to 15-20 ft. lbs. These nuts can be identified by their shape and by the absence of a lockwasher.

DESCRIPTION: "Spherical joint" suspension using ball and socket type joints to connect upper and lower control arms to steering knuckle. On cars with conventional coil springs, the shock absorber is mounted within the coil spring between seat on lower control arm and spring pocket on frame. On cars with air suspension, the shock absorber is mounted between bracket at outer end of lower control arm and bracket on frame. Threaded type bushings are used to connect control arms to control arm shafts.

CADILLAC FRONT SUSPENSION ASSEMBLY

ADJUSTMENT

CHECKING & ADJUSTING: Before checking or adjusting front wheel alignment, check and correct any looseness in spherical joints, steering gear, and connections.

CONTINUED ON NEXT PAGE

1957-60 CADILLAC FRONT SUSPENSION (Cont.)

Check and correct standing height (*see "Trim Dimensions" below*). Inflate tires to correct pressure and check for runout. Make sure cars with coil springs are at curb weight (not necessary on air suspension cars).

►*AIR SUSPENSION CAR CHECKING & ADJUSTING NOTE:* When checking cars with air suspension (exc. Eldorado Brougham), make sure car has reached its normal height. On Eldorado Brougham, open any door and allow car to come to normalized standing height before checking each point. *See "Cadillac Air Suspension" and "Cadillac Eldorado Brougham Air Suspension" for height adjustment and specifications.*

Tire Inflation: Series 60, 62 & Eldorado Brougham - 24 lbs. (front & rear). **Series 75** - 28 lbs. (front & rear). **Commercial** - 24 lbs. (front), 30 lbs. (rear).

Steering Axis Inclination: 4° at 0° camber. Not adjustable.

Caster: 0° to Neg. 1° (Exc. 1959-60 Series 75 & Comm.); Neg. ¾° to Neg. 1¾° (1959-60 Series 75 & Comm.). Adjustment must be within ½° or less on both sides. *See "Shimming Procedure" below.*

Camber: Neg. 3/8° to Pos. 3/8° (1/4° to 1/2° more positive camber preferred on left wheel). *See "Shimming Procedure" below.*

Toe-In: Coil Spring Cars - 3/16-1/4". *NOTE - To avoid interference, tie-rod clamp screws must be in a downward position.*

Air Suspension Cars - 1/8"±1/32" (1957 Eldorado Brougham); 1/16-1/8" (1958 Models); 1/16"±1/32" (1959-60 Models). After adjustment, tie-rod clamp screws must be in downward position to avoid interference.

Toe-Out on Turns: With outer wheel at 20°, inner wheel 22°40'.

Shimming Procedure: Caster and camber adjustments are made by adding or removing shims between upper control arm mounting shaft and frame mounting bracket. To change caster, remove or add shims at one of the mounting bolts. Addition of shims at front bolt or removal of shims at rear bolt will **decrease** positive caster. Removal of shims at front bolt or addition of shims at rear bolt will **increase** positive caster. To change camber, add or remove shims of equal thickness at both mounting bolts. Addition of shims at both bolts will **decrease** positive camber. Removal of shims at both bolts will **increase** positive camber. Tighten both upper and lower control arm shaft bolts to 130-140 ft. lbs. after changing shims. Camber and caster adjusting shims are furnished in .0149", .0418", & .1046" thicknesses. *See tables below for approximate amount of change made by adding or removing shims.*

Shim Selection

Shim Size	Caster Change (Shim at rear bolt)	Camber Change (Shim at both bolts)
.0149"	1/6°	1/15°
.0418"	1/2°	1/5°
.1046"	1 1/16°	1/2°

►*CASTER CHANGE NOTE:* When possible, make caster adjustments by changing shims at **front bolt** as the resulting camber change will be small.

►*SHIM PACK THICKNESS NOTE:* If more than ¼" total thickness of shims are necessary to bring adjustment within specifications, check for bent or damaged parts.

Trim Dimension Adjustment (Cars With Coil Springs): Before checking front trim height, make sure that trunk is empty and the gas tank full. Normalize position of springs by working bumper up and down and release slowly, permitting car to assume normal position. Measure distance from top of lower control arm to center of second lowest rivet on front of frame side rail. The standing height should be equal on both sides of car within 3/8". If heights are unequal, adjust low side by installing a shim between top of spring and seat inside the frame.

1957 Front Trim Heights

Model	Height
All Models (Exc. Below)	4 11/16-5 7/16"
6237S, 6267S	4 3/4-5 1/2"
7523, 7533	5 7/16-6 3/16"
85 Comm.	5 5/16-6 1/16"

1958 Front Trim Heights (Conventional Cars)

Model	Height
All Models (Exc. below)	5-5 1/2"
7523, 7533 & 86 Comm.	5 9/16-6 1/16"

1959-60 Front Trim Height (Conventional Cars)

Series	①Height
All Series (Exc. Below)	5 1/8"
75 & Comm. Series	5 7/8"

① - Plus or minus ¼".

Trim Height Adjustment (Air Suspension Cars): *See "Cadillac Air Suspension" or "Cadillac Eldorado Brougham Air Suspension".*

FRONT COIL SPRING REPLACEMENT: *See "Lower Control Arm" below.*

REMOVAL & INSTALLATION

FRONT SHOCK ABSORBER (Cars With Coil Springs): *(NOTE - Bushing in lower mounting bracket on shock absorber is not replaceable. If worn or damaged, the complete shock absorber must be replaced).*

Removal: Raise hood and remove shock absorber upper retaining nut, retainer, and rubber grommet at upper suspension arm frame mounting bracket *(NOTE -* Upper stem of shock absorber is square so that it may be held with a wrench when removing nut). Remove two screws holding shock absorber to lower spring seat and remove shock absorber from spring assembly.

Installation: Install retainer and rubber grommet on shock absorber upper stem. Install shock absorber assembly up through coil spring and guide stem through tower in crossmember. Place lower end in position on lower spring seat and install lockwashers and screws. Install grommet, retainer, and nut on upper stem and tighten nut.

►*SHOCK ABSORBER APPLICATION:* See *"Shock Absorbers" on Car Model pages.*

FRONT AIR SPRING REMOVAL & INSTALLATION: *See "Cadillac Air Suspension" or "Cadillac Eldorado Brougham Air Suspension".*

UPPER SPHERICAL JOINT REPLACEMENT: *(NOTE -* To check condition of joint, lubricate it first, then using a regular spherical joint stud nut and a second nut as a locknut, turn joint in its socket with a torque wrench. It should require 2-4 ft. lbs. to rotate joint. Replace if joint is too loose or too tight.

Removal: Raise front of car and place jack stands under lower suspension arms. Remove front tire and wheel, then remove cotter pin from joint stud. Strike steering knuckle with a hammer in area of joint stud to loosen it. Raise upper suspension arm so that joint clears knuckle. With a 5/16" drill, drill out all four joint mounting rivets being careful to avoid damage to mounting holes. Remove spherical joint.

Installation: Install new spherical joint on upper control arm with bolts, nuts, and lockwashers (these items are

CONTINUED ON NEXT PAGE

1957-60 CADILLAC FRONT SUSPENSION (Cont.)

provided in replacement kit). Tighten nuts to 20-25 ft. lbs. Position spherical joint stud in steering knuckle, install stud nut and tighten to 50-60 ft. lbs. Install cotter pin, then install tire and wheel.

LOWER SPHERICAL JOINT REPLACEMENT: *(NOTE* - The lower joint is designed to turn freely in its socket and cannot be checked with a torque wrench. To check, note amount of free play as joint is worked vertically in its socket. This movement should not exceed 1/16".

Removal: Raise front end of car and place stands under forward portion of frame side members. Place a hydraulic jack under lower control arm spring seat and raise arm approximately 1" (measured at its outer end). Remove cotter pin and nut from joint stud. Strike steering arm with a hammer in area of joint to break it loose. Remove four lower joint nuts, lockwashers, and bolts. Raise arm sufficiently to allow joint to be removed.

Installation: Install joint on lower control arm with four bolts, lockwashers, and nuts and tighten to 35-40 ft. lbs. *(NOTE* - Head of bolt should be under joint flange). Position joint stud in steering arm mounting hole and lower hydraulic jack to allow joint to seat itself in steering arm. Install stud nut and tighten to 50-60 ft. lbs. Install cotter pin.

STEERING KNUCKLE REPLACEMENT: Removal - Raise front end of car and place jack stands under lower control arms. Remove wheel, then remove cotter pin and nut from upper joint stud. Strike steering knuckle in area of joint to break it loose. Raise upper control arm and allow top of knuckle to move outward. Remove upper nut on knuckle and two lower nuts on side of brake backing plate (leave two lower screws in position). Remove brake backing plate and wire it to a convenient location to prevent damage to brake hose. Remove and discard gasket on spindle between knuckle and backing plate. Separate knuckle from steering arm.

Installation: Install two lower legs of steering knuckle on two lower screws (in steering arm). Install new gasket on spindle. Install backing plate on two lower screws and install lockwashers and nuts. Tighten to 90-100 ft. lbs. Install upper screw through backing plate and knuckle. Install lockwasher and nut and tighten to 85-95 ft. lbs. Position upper spherical joint in knuckle. Install nut and tighten to 50-60 ft. lbs. Install cotter pin. Install brake drum, tire and wheel assembly.

UPPER CONTROL ARM: Removal - Disconnect upper spherical joint from steering knuckle *(see "Steering Knuckle Replacement" above)*, then remove mounting bolts on control arm shaft and remove control arm assembly.

Disassembly: Place control arm shaft in vise and remove threaded bushings from arm and shaft. Remove seals and suspension arm from shaft. Place suspension arm in vise and drill out with a 5/16" drill or grind off the four spherical joint rivets and remove joint.

Reassembly: Install new rubber seals on mounting shaft and lubricate threads of shaft. Center shaft in position in control arm and install bushing into arm and onto one end of shaft *(NOTE* - Lubricate new bushings with carbon tetrachloride or penetrating oil for easier installation). Tighten bushings to 140-150 ft. lbs. Install Upper Control Arm Spreader, Tool J-6590, between arms and tighten finger tight. Then, using a wrench, tighten tool *two additional flats*. Install other bushing in arm and onto shaft and tighten to 140-150 ft. lbs. Remove tool from arms and center shaft between arms by turning shaft in bushings. Install new spherical joint assembly *(see "Upper Spherical Joint Replacement" above)*.

Installation: Install arm in position on frame mounting bracket with mounting bolts and tighten to 130-140 ft. lbs. (1957-Early 1960); 65-85 ft. lbs. (Late 1960). *See "1960 Upper & Lower Control Arm Mounting Bolt Production Change" above.* Position joint stud in steering knuckle hole, then install nut and tighten to 50-60 ft. lbs. and install cotter pin.

LOWER CONTROL ARM (Cars With Coil Springs): Removal - Raise front end of car and place jack stands under forward parts of frame side members. Place hydraulic jack under control arm to be removed, then disconnect front stabilizer link on side from which control arm is to be removed. Remove shock absorber (see "Shock Absorber Replacement" above). Make sure hydraulic jack is supporting lower control arm, then remove lower spherical joint pin and nut, and strike steering arm in area of joint to break it loose. Move wheel downward and outward so it clears joint. Slowly lower hydraulic jack and remove spring and rubber insulator. Remove four bolts attaching control arm shaft to frame member, and remove control arm.

Disassembly: Place control arm shaft in vise and remove threaded steel bushings from arm and shaft. Remove seals and control arm assembly from shaft. Remove four joint mounting nuts and bolts and remove joint.

Reassembly: Install new rubber seals on shaft and lubricate threads. Center shaft in position in control arm and install bushing into arm and onto one end of shaft *(NOTE* - Lubricate bushings with carbon tetrachloride or penetrating oil for easier installation). Tighten bushing to 195-205 ft. lbs. Install Lower Control Arm Spreader, Tool J-6591, between arms, tighten center bar finger tight, then with a wrench, tighten *two additional flats*. Install other bushing in arm and onto shaft and tighten to 195-205 ft. lbs. Remove tool and center control arm shaft between arms by turning shaft in bushings. Install lubrication fittings. Install spherical joint with four bolts and tighten to 35-40 ft. lbs.

Installation: Install control arm shaft to crossmember and tighten bolts to 60-70 ft. lbs. Tape upper rubber insulator to top (flat end) of spring and place spring in upper seat of frame crossmember. Rotate spring so that lower tang end will fit in formed depression of lower control arm spring seat when arm is in position. With hydraulic jack placed under lower control arm, raise arm into position. Guide spring into place with tang end bisecting hole in spring seat. Guide spherical joint stud into steering knuckle and install nut. Tighten to 50-60 ft. lbs. Install cotter pin. Connect stabilizer link to lower spring seat. Install shock absorber. Remove car from jack stands and check front end alignment.

LOWER CONTROL ARM (Cars With Air Suspension): Removal - Raise car and place jack stands under front and rear frame side members, and remove front wheel. Exhaust air from system by opening drain cock on accumulator tank. Disconnect stabilizer link from lower control arm and disconnect shock absorber. Remove lower spherical joint cotter pin and nut, and strike steering arm with a hammer in area of joint to break it loose. Remove control arm shaft mounting bolts at frame front crossmember, and remove lower control arm.

Disassembly & Reassembly: Same as for control arms used with coil springs. *See "Lower Control Arm (Cars with Coil Springs)" above.*

Installation: Install control arm shaft to frame crossmember and tighten bolts to 60-70 ft. lbs., then install spherical joint stud in steering knuckle and tighten nut to 50-60 ft. lbs. Connect shock absorber and stabilizer linkage. Pull out lift valve control handle on instrument panel, close drain cock on accumulator tank and replenish air supply in tank. Install wheel, lower car, and push in lift valve control handle.

1958-60 CADILLAC REAR SUSPENSION

All Series, Exc. Commercial Chassis (1958-60)

►*JACKING & HOISTING: See "Jacking & Hoisting Precautions".*

►*TOWING CARS WITH AIR SUSPENSION: See "Cadillac Air Suspension".*

►*1960 REAR SUSPENSION NOTE: Ball joint, bracket, control yoke and rear axle housing are different than for previous models. The new parts are not interchangable on earlier cars.*

DESCRIPTION: Rear suspension linkage consists of two lower control links and an upper control yoke. Front ends of lower control links are connected to a body mounting bracket that is welded part of frame. Rear ends of lower control links are attached to a bracket on rear axle housing. The two front arms of upper control yoke are attached to a frame crossmember just forward of the rear axle. To permit movement of the rear axle as rear wheels move up and down, a spherical rubber joint is used in rear axle end of control yoke, and rubber bushings are used in both ends of lower control links. The upper yoke is designed to take all thrust forces resulting from cars turning or cornering. Rear shock absorbers are mounted between lower control arm mounting brackets at rear of axle and a bracket on car frame. Coil springs are mounted with lower end seated on lower control link and upper end seated in tower bracket welded to frame side member. *(NOTE* - With air suspension, the coil springs are replaced by air springs in the same location).

ADJUSTMENT

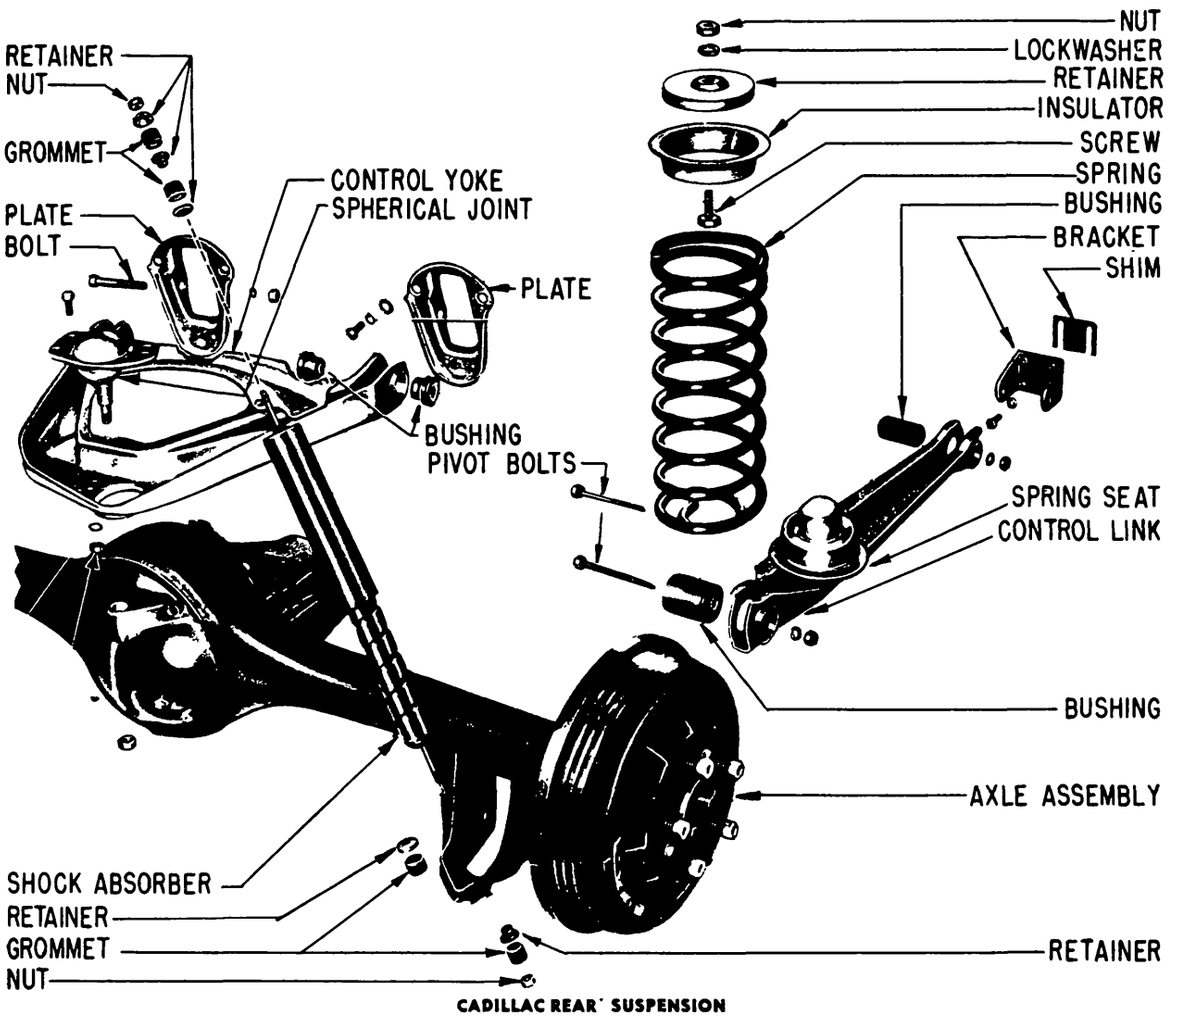
TRIM DIMENSION ADJUSTMENT (Cars With Coil Springs): *(NOTE - On cars with air suspension, see "Cadillac Air Suspension" or "Cadillac Eldorado Brougham Air Suspension").* Before checking rear trim height, make sure trunk is empty and gas tank full. Normalize position of springs by working bumper up and down and release slowly, permitting car to assume its normal position. Measure distance from top of rear axle housing to underside of frame at a point directly above axle housing, (see table below). Rear standing heights should be equal within 1/2" on both sides of car.

1958 Rear Trim Height

Model	① Coil Springs	② Air Susp.
All Models (Exc. Below)	5 5/8"	4 1/2"
7523, 7533	7"	5 3/8"
86	4 1/8"	

① - Plus or minus 3/8". ② - Plus or minus 1/4".

1959 Rear Trim Height



Series & Model	① Coil Springs	② Air Susp.
60, 62, 63 (All Models)	5 7/8"	4½"
64 (All Models)		4½"
67 (All Models)	7 1/16"	5 13/32"
68 Commercial ③	4 1/8"	

① — Plus or minus 3/8". ② — Plus or minus ¼".
③ — Leaf spring.

1960 Rear Trim Height

Series & Model	① Height
60, 62, 63 (All Models)	6 1/8"
75 (All Models)	7 1/16"
68 Commercial ②	4 1/8"

① - Plus or minus 3/8". ② - Leaf spring.

CADILLAC REAR SUSPENSION

REAR AXLE PINION ANGLE: *(NOTE* - All pinion angles given are at the air suspension standing height; on cars with coil springs, it will be necessary to add weight to trunk until standing height is equal to that specified for air suspension cars). Place car on a wheel alignment machine or on a "drive-on" type hoist (all wheels must be on a level surface), locating it so slots in pinion shaft universal joint yoke on differential are vertical. Disconnect universal joint at differential and allow propeller shaft to hang down. Set Axle Angle Checking Gauge, J-6997, for proper pinion angle (3° - Series 60, 62 & 75.4° - Series 70, Eldorado Brougham), then place proper combinations of shims under adjustable leg of tool to privide desired angle for checking. *(NOTE - Three shims are furnished with each tool; the smallest represents 1°, the next 2°, and the largest 3°).* Hold Tool J-6997 against bottom plate of frame tunnel with adjustable leg forward, and adjust setscrew until bubble in level is exactly centered (tool is now set for exact pinion angle). Position rounded projections on rear edge of pinion angle tool in slots in pinion yoke and check the level. If air bubble is exactly centered, pinion angle is correct. If bubble is off center, note which line on glass that bubble most nearly touches. Each line represents 1/16" shim requirement behind the lower link front mounting bracket. If bracket is too far forward, shims must be added; and if too far to rear, shims must be removed. To install or remove shims, loosen all four bolts securing each lower control link bracket to No. 4 body bracket until lockwashers are free. With a long bar placed at front end of control link between bushing and frame bracket, pry rearward. Add or remove shims as required. Shims are furnished in the following thicknesses: 1/16" (Part No. 1465858), 3/32" (Part No. 1465859), 1/8" (Part No.

CONTINUED ON NEXT PAGE

1958-60 CADILLAC REAR SUSPENSION (Cont.)

1465860). Tighten each lower control link mounting bracket screw to 35-40 ft. lbs., and recheck pinion angle with gauge. *(CAUTION - Equal thicknesses of shims must be installed or removed from right and left control links).* Connect propeller shaft, and lower car to floor. Remove any weights added for checking purposes.

REMOVAL & INSTALLATION

SHOCK ABSORBERS: (Removal) - Raise rear of car and place jack stands under axle housing. Remove shock absorber upper retaining nut, retainer and grommet. *(NOTE* - Upper stem of shock absorber is square at top so it can be held by a wrench to prevent turning when removing retaining nut). Remove lower retaining nut, retainer, and grommet. *CAUTION - Under no circumstances should rear end of car ever be raised in such a way that rear suspension is in rebound position with shock absorbers disconnected.*

Installation: Reverse removal procedure.

►*SHOCK ABSORBER APPLICATION: See "Shock Absorbers" on Car Model pages.*

CONTROL YOKE SPHERICAL JOINT (Coil & Air Spring Cars): Removal - Disconnect spherical joint from mounting bracket *(see "Control Yoke" below),* then grind off heads and punch out all four spherical joint mounting rivets. Do not damage mounting holes.

Installation: Position spherical joint on yoke and secure with four bolts, nuts, and lockwashers provided in service replacement kit. Tighten bolts to 35-40 ft. lbs. Install bolts with heads upward. To complete installation, *see "Control Yoke" below.*

CONTROL YOKE (Coil & Air Spring Cars): Removal - Raise car and place jack stands under frame side rails at front and rear. If car is equipped with air suspension, exhaust all air from system by opening drain valve on bottom of accumulator tank. Place a jack under forward end of differential housing and raise slightly to relieve tension on drive line. Remove cotter pin and nut from spherical joint stud and strike mounting base with a hammer in area of joint to break it loose. Remove bolts securing front control yoke mounting plates to frame crossmember, then remove yoke over top of rear axle housing. Remove control yoke front attaching bolts, and remove plates.

Installation: Position mounting plates approximately perpendicular to control yoke front attaching flanges and install attaching bolts. Tighten to 85-95 ft. lbs. Position yoke assembly over differential housing and secure front mounting plates to frame crossmember. Adjust jack at front end of differential housing until spherical joint stud will go into mounting hole, then install nut on stud and tighten to 80 ft. lbs. Install cotter pin, and remove jack from end of differential housing. On air suspension cars, pull out lift control handle on instrument panel, close drain valve, and replenish air supply in accumulator tank through service valve. Lower car and push in lift valve control handle.

COIL SPRING REMOVAL & INSTALLATION: *See "Lower Control Link" below.*

AIR SPRING REMOVAL & INSTALLATION: *See "Cadillac Air Suspension" or "Cadillac Eldorado Brougham Air Suspension".*

CONTROL LINK (Coil & Air Spring Cars): Removal - Raise rear end of car and place jack stands under frame side rails, then remove wheel. On cars with air suspension exhaust air from system by opening drain valve on bottom of accumulator tank, then disconnect leveling valve adjusting link from lower control link *(CAUTION - Do not disturb adjusting nuts).* On all cars, disconnect parking brake line clamp on control arm. On cars with coil springs, place hydraulic jack under control link and relieve tension on rear pivot bolt. On all cars, remove rear pivot bolt. On air suspension cars, remove front pivot bolt, then remove link from mounting brackets. On coil spring cars, slowly lower hydraulic jack and remove rear coil spring and rubber insulator. Remove front pivot bolt and remove control link from mounting bracket.

Installation: On all cars, install control link in position in front mounting bracket and install pivot bolt from inner side of bracket, then install lockwashers and nut on pivot bolt but do not tighten nut. On coil spring cars tape upper rubber insulator to top of spring and place spring in upper seat of frame tower. Seat bottom of spring on control link spring seat and, with hydraulic jack placed under control link, raise rear end of link into position. On air suspension cars, slide control link into position in axle bracket. On all cars, install rear pivot bolt, lockwasher, and nut, but do not tighten nut. Install brake line bracket to control link. On air suspension cars, raise rear axle until leveling valve linkage will connect freely, then connect linkage (this is normal standing height). On coil spring cars, lower car to floor. On all cars, tighten nuts on front and rear pivot bolts to 85-95 ft. lbs. *(NOTE* - Bushings on lower control arm must be tightened with car at normal standing height). On air suspension cars, pull out lift control knob on instrument panel, close drain valve on accumulator tank, and replenish air supply in tank through the service valve. Lower car to floor and push in lift valve control knob.

CHECKER FRONT SUSPENSION

Checker Superba (1960)

Checker Cab (1960)

DESCRIPTION: Independent type with steering knuckle connected directly to upper and lower control arms with ball joint assemblies. Shock absorbers are direct acting type mounted within the coil springs. Rubber type bushings attach upper and lower control arms to control arm shafts.

ADJUSTMENT: Steering Axis Inclination - 7° at 1° Camber. Not adjustable.

Caster: Pos. 2° (Superba); Pos. 1° (Checker Cab). To adjust, loosen two bolts attaching upper control arm to frame bracket and remove or add shims at one or the other mounting bolt. *NOTE - These shims are located between inner side of shaft and frame bracket.* To increase positive caster, add shim at front bolt or remove shim at rear bolt. To increase negative caster, remove shim at front bolt or add shim at rear bolt. The addition or removal of one 1/16" shim will change caster ¼°.

Camber: Pos. ½° to Pos. 1½° (Superba); 0° to Pos. 1° (Checker Cab). To adjust, remove or add shims equally at both front and rear shaft mounting bolts. To increase positive camber, add shims equally at both bolts. To decrease positive camber, remove shims equally at both bolts. *NOTE - Total shim thickness at either bolt must not exceed 9/16".*

Toe-In: 1/16" to 1/8" (All Models). To adjust, loosen clamp bolts on adjusting sleeves at outer end of each tie rod and turn both adjusting sleeves equally in opposite directions to obtain correct toe-in. *NOTE - On cars with power steering, the engine must be running when toe-in adjustments are made.*

Toe-Out on Turns: With inner wheel at 20°, outer wheel should be 17.5°. Not adjustable.

REMOVAL & INSTALLATION: *See "1954-56 Ford Pass. Cars, Lincoln & Mercury Front Suspension" in this section.*

1954 CHEVROLET

Ch vr let Pass. Cars (1954)

►**FRONT SUSPENSION UNIT ASSEMBLY REMOVAL:** Entire assembly is mounted on special cross-member bolted to frame side rails and can be removed as a unit for servicing and overhaul by taking out these mounting bolts.

DESCRIPTION: New design, independent, linked parallelogram type with direct acting shock absorbers, coil springs, and new type upper control arm (not part of shock absorber assembly). Cross-member on which suspension unit mounted has new "tower type" bracket at each end for spring housing, shock absorber mounting, and upper control arm shaft mounting.

CHECKING & ADJUSTMENT: First check entire front end for excessive play and wear, check steering gear adjustment, wheel bearing adjustment, tire inflation pressure (see data below), wheel balance and run-out (run-out should not exceed 1/16"), then place car on level floor and check front end specifications as follows:

Tire Inflation Pressure: For each type tire (Cold): **Pass. Cars** (6.70x15—4 ply)—24 lbs. frt. & rear. **Station Wagon & Sedan Delivery** (6.70x15—6 ply) 26 lbs. front, 30 lbs. rear.

Riding (Spring) Height: Rock car sidewise several times and allow it to settle, then measure vertical distance from center of pivot pin at each end of lower control arm to floor. Difference between these two measurements should be 1⅝" ± ¼". If difference between measurements less than this amount, or if unequal on both sides of car, install spring shims or replace springs (see Spring data).

Kingpin Inclination: 4° ± ½° crosswise.

Caster: Pos. ½° ± ½°.

Adjustment—Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting from rear bushing at outer end of upper control arm, insert Allen wrench through hole, turn pivot bolt until exact caster setting secured, then adjust camber.

►*CAUTION—Caster adjustment will change camber unless pivot bolt rotated in full turns only.*

Camber: Pos. ½° ± ½°.

Adjustment—After adjusting Caster (above), rotate pivot bolt not more than ½ turn in either direction to secure correct camber. Entire range of adjustment is secured in ½ turn of the pivot bolt.

Toe-In: 1/8"±1/16".

Adjustment—Loosen clamp bolts at each end of **left hand tie rod** and turn rod (right hand tie rod is one-piece non-adjustable type), tighten clamp bolts to 8-12 ft. lbs.

►*CAUTION—Align tie rod ends before tightening clamp bolts (ball studs will bind if not aligned).*

Toe-Out on Turns: With inner wheel turned 20°, outer wheel should be turned 17°40'. No adjustment, replace steering arm if incorrect.

SHOCK ABSORBER REPLACEMENT: *Not necessary to disturb Front Suspension Assembly.* Remove nut on shock absorber upper threaded end while holding stem from turning with ¼" wrench (this nut located on top of spring housing tower), lift off grommet retainer and grommet. Remove nut and lockwasher from shock absorber lower mounting bracket stud (on underside of lower spring seat), lower shock absorber and mounting bracket assembly down and out through hole in spring seat.

►**Installation Note**—When installing rubber grommet assemblies on shock absorber threaded ends, hold end from turning with a ¼" open-end wrench, tighten nut on stem until it bottoms on shoulder. This will provide correct compression of grommets.

COIL SPRING REPLACEMENT: Disconnect stabilizer link at lower control arm bracket, remove shock absorber on side on which spring being removed. Support car on jack stands placed under frame side rails. Place hydraulic jack under lower control arm inner shaft, remove nuts and lockwashers from control shaft bracket bolts, drive out bolts, lower arm slowly to relieve spring pressure, lift spring out (CAUTION—remove all shims used with old spring). Install spring by reversing this procedure.

►**Spring Installation Caution**—Service replacement springs are checked for height and are furnished with necessary shims wired to the spring.

►*CAUTION—These shims must be installed on top of the spring to insure correct riding height of the car.*

LOWER CONTROL ARM REPLACEMENT: Lower control arm assembly must be removed from the car for replacement of arm, inner shaft, or shaft bushings. Other operations can be performed without removing the assembly.

Removal—Remove wheel and tire assembly, remove front spring (see Coil Spring Replacement), disconnect tie rod from steering arm, remove nut on forward end of lower control arm pivot bolt, unscrew pivot bolt, lift control arm assembly out.

Lower Control Shaft & Bushing Installation: Hold control shaft in vise, then place new seals on each end of shaft (push seals up onto shaft shoulders). Position control arm on shaft using a scale to center arm on shaft. *NOTE - Gauge J-3184 cannot be used because of welded reinforcement plate on inner face of arms.* Thread bushings on shaft and into control arm making sure that threads on bushings index with threads in arm and engage properly. Tighten bushings to 85-100 ft. lbs., then slip seals down into place.

Lower Pivot Bolt & Bushings: Bushing in lower end of knuckle support should be installed from rear-to-front and tightened to 150-170 ft. lbs. Place new seals over exposed ends of bushing, position control arm so that knuckle support is centered in outer end of arm, start pivot bolt through arm from rear-to-front, thread bolt through knuckle support bushing using care not to disturb centered position of support in control arm, continue to screw pivot bolt in and through opposite eye of control arm until bolt head firmly contacts rear face of arm (NOTE—If bolt threads do not index properly with threads in opposite eye of arm, use "C" clamp to compress ends of arm slightly until threads index and bolt can be turned through arm freely). Tighten pivot bolt to 100-200 ft. lbs., then install locknut on end of bolt and tighten nut to 90-120 ft. lbs. Use wire hook to slip seals down off ends of bushing into their seats.

UPPER CONTROL ARM REPLACEMENT: Control arm should be assembled on control shaft in cross-member tower bracket and checked for free movement throughout entire range before connecting knuckle support.

Removal—Support car on jack stand placed under lower spring seat (to keep spring compressed and lower control arm in place), remove wheel and tire assembly. Take out lubricant fitting in rear bushing at outer end of control arm, unscrew both front and rear bushings from arm, remove seals from pivot pin ends. Take out clamp bolt in upper end of knuckle support, slide pivot pin out (use ¼" Allen wrench in pin recess to assist in removal), swing knuckle support out and free of upper control arm. Unscrew front and rear bushings from control arm at inner control shaft (NOTE—On left side of car, remove sheet metal splash guard over steering gear housing for access to rear bushing), lift control arm off shaft. To remove shaft from frame bracket, use Remover & Replacer Tool J-2958 and pull shaft out toward front of car.

►**Replacement Control Arm Note**—Arms furnished with threads in bushing holes slightly undersize to insure snug bushing fit when new arm installed.

►**Replacement Control Shaft Note**—New shafts are marked by "F" on end to insure correct installation ("F" end toward front of car) and diameter of threads which screw into spring housing tower are oversize to insure correct fit (CAUTION—these threads must be lubricated when installing new shaft to avoid tearing threads).

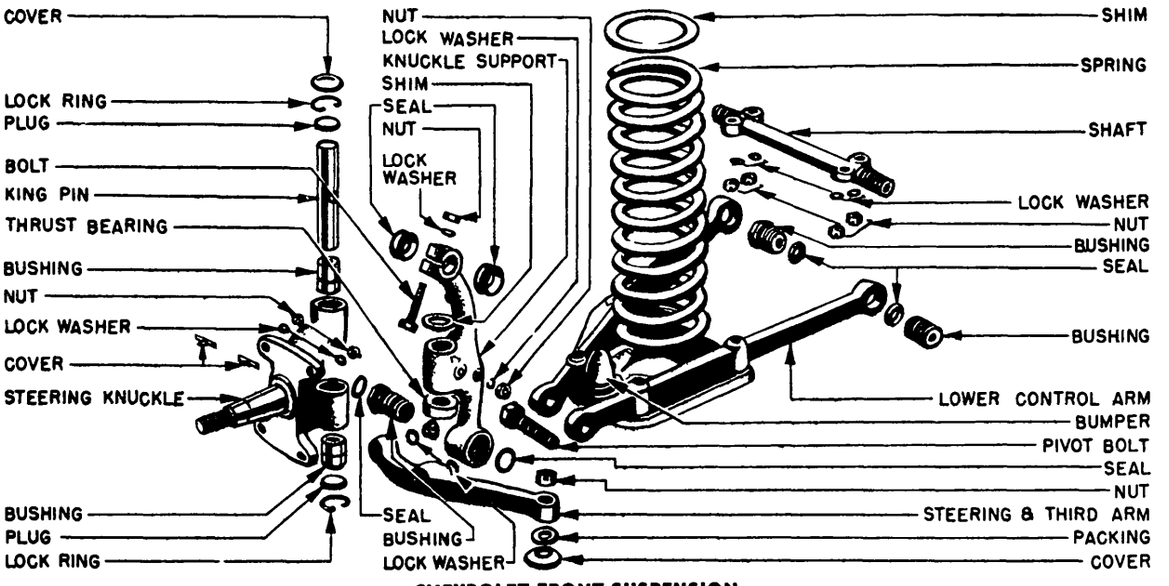
Upper Control Shaft & Bushing Installation: Lubricate threads on new shaft to avoid tearing during installation, see that shaft end marked "F" (larger diameter end) toward front of car, use Remover & Replacer Tool J-2598 to install shaft from front-to-rear of spring housing until rear end projects exactly 1⅛" back of housing (CAUTION—Do not back shaft out which will leave shaft loose in housing—rear end is smaller diameter and threads are tapered). Install new seals on ends of shaft, position control arm on shaft using a scale. Lubricate the bushing inner and outer threads, start both front and rear bushings on shaft and into arm (CAUTION—see that control arm not moved out of position more than necessary to start bushing threads—see Caster Adjustment Caution below), turn bushings in until head seats against arm, then tighten bushings to 30-40 ft. lbs. (CAUTION—this is new specification to prevent stripping of threads and distortion and binding of arms). See that seals seated on their seats, install lubricant fittings in bushings, lubricate arm. Check installation for free movement throughout entire range with rubber bumper removed (arm should fall of own weight).

►**Caster Adjustment Caution**—The thread starting points for control arm and shaft are not controlled and it may be necessary to move arm out of centered position by ½ thread pitch or 3/64" to start bushings in arm. This will require correction by Caster Adjustment after suspension assembly completed.

Upper Pivot Pin & Bushings: Position control arm on upper end of knuckle support, install pivot bolt through arm and knuckle support with Allen wrench hole toward rear of car, center bolt in support, install lock bolt in support and tighten to 30-35 ft. lbs. Place new seal on each end of pivot bolt. Lubricate both inner and outer threads of bushing. Thread front bushing on pivot bolt, center knuckle support in arm, thread bushing into arm (CAUTION

CONTINUED ON NEXT PAGE

1954 CHEVROLET (C nt.)



—carefully index threads on bushing and arm and see that support does not move out of centered position when starting threads in arm). Install rear bushing similarly. Screw both bushings in until heads seat against arm, then tighten bushings to 30-40 ft. lbs. (CAUTION—this is new specification to prevent stripping of threads and distortion and binding of arms).

KINGPIN BUSHING REPLACEMENT: ***Not necessary to remove knuckle support from car (bushings are "floating" type).*** New bushings are machined to finished size and do not require reaming.

Removal—Support car with jack under lower spring seat, remove wheel and tire assembly. Remove kingpin lock pin, upper bearing plug cover, upper and lower lock rings, and lubrication fittings. Drive sharp drift punch through lower plug, drive kingpin up until upper plug is forced out, then drive kingpin down and remove from below. Lift off steering knuckle and thrust bearing, remove floating bushings from knuckle support.

Installation—Install new bushings in knuckle support (CAUTION—oil grooves in bushing must line up with lubricant fitting hole in knuckle and bushings must be free in knuckle support and on kingpin). Install thrust bearing between lower yoke of steering knuckle and support with shield on bearing upward, install kingpin from below lining up lockpin slot with hole in support. Check knuckle endplay with a feeler gauge, install steel shim between support and top of steering knuckle if this clearance exceeds .006". Install kingpin lock pin, bearing plugs, lock rings, and bearing plug cover.

SPRINGS: Springs have one end ground flat which should be placed at top with shim (when used) between top of spring and spring seat in cross-member. Lower end is not ground and should be fitted in recess in spring seat on lower control arm.

CHEVROLET FRONT SUSPENSION

Model	Color Mark	Part No.
Convertible	Black	3703787
Others (Synchro-mesh)	Black	3703788
All Powerglide	Black	3703787

Spring Height Correction—If spring height too low (riding height less than 15⅞"), install not more than two 599810 Shims (1/16" thick) on top of spring.

►***CAUTION***—If more than two shims required to secure correct riding height, replace spring (additional shims will cause spring coils to bottom before rubber bumper on lower control arm stops arm.

►***REPLACEMENT SPRING CAUTION***—Shims furnished with new springs (wired to spring) must be installed with the spring (riding height will not be correct if shims omitted).

1955-60 CHEVROLET

Chevrolet Pass. Cars, Exc. Corvette (1955-60)

DESCRIPTION: Front suspension utilizes short and long arms with spherical type joints connecting control arms and steering knuckles. Coil springs and direct acting shock absorbers are mounted between spring seats on lower control arms and spring pockets in front cross member Inner ends of upper and lower control arms are mounted on rubber torsion bushings which, in turn, are on forged steel shafts bolted to front cross member (no lubrication required). System uses a forged steering knuckle that is connected directly to upper and lower control arms at spherical joints. This knuckle has brake backing plate, anchor pin, and steering arms bolted to it

ADJUSTMENT: Before making adjustments of front suspension steering geometry check for following: Loose or improperly adjusted steering gear, steering gear housing loose at frame, play or excessive wear in spherical joints, loose tie rod or steering connections, improper front spring heights (see below), underinflated or unbalanced tires, wheel bearings improperly adjusted, shock absorbers not operating properly. *Mak adjustments at curb w ight.*

Shimming Procedure: Adjustment is made by means of shims between upper control arm inner support and support bracket attached to frame side rail. Shims may be changed at either front or rear of inner shaft to change caster, or at both points equally to change camber. Addition of shims at front bolt or removal of shims at rear bolt will decrease positive caster. A 1/32" shim difference will change caster approximately 1/4°. Adding shims at both front and rear of inner shaft will change camber 1/6°. To adjust, loosen upper inner shaft-to-bracket bolts and add or remove shims as required.

►*1955 CAMBER ADJUSTMENT CORRECTION:* If it is found that proper camber cannot be obtained even after removal of all shims, it will be necessary to reposition lower control arm 1/8" inward. New position provides over 1° camber which in turn can be adjusted through addition of shims. Added shims can be moved forward or backward to obtain proper caster. To reposition lower control arm, remove lower control arm shaft. Scribe mark on forward and rear edge of front crossmember, corresponding to present centers of forward and rear inner lower control arm bolt holes in front crossmember. Weld both inner holes shut and redrill new inner holes 1/8" inward from marks scribed above. Weld both outer holes shut and reinstall lower control arm shaft on new inner holes. Using lower control arm shaft as a template, drill two new outer holes and secure with bolts. Recheck camber and add shims as required. Adjust caster by moving shims (see below).

Steering Axis Inclination: (1955-56) 3½°±½°, (1957) 3-4°, (1958-60) 7¼°±½°

Caster: (1955) 0°±½°, (1956-57) 1°±½°, (1958-60) 0°±½°

►*1958-59 AIR SUSPENSION CASTER NOTE· Cast r is* 1½°±½°.

Camber: Pos ½°±½°

Toe-In: 1/8" to 1/4" (Std Susp) 0 to 1/8" (Air Susp) Equally divided between wheels

Toe-Out on Turns: With inner wheel at 20°, outer wheel should be 18°10' (1955-57); 18½° (1958-60). Not adjustable

RIDING HEIGHT (COIL SPRING CARS): Position car on a smooth floor, then bounce and rock car several times and allow it to settle to normal height Proceed as follows

Fr nt Springs: Measure distance from floor to center of front inner pivot of lower control arm, then measure the

CONTINUED ON NEXT PAGE

1955-60 CHEVROLET (C nt.)

distance from floor to lower face of lower steering knuckle boss for spherical joint *The difference b - twe n th se two measurements should be as indicated in table below.* Measure opposite side of car in the same manner. Differences between the two sides should be closed. If necessary to correct height, springs must be replaced These springs do not have flat ends and shims should not be used

④–If equipped with 8.50x14 tires, add 19/32" to specs.

►*REAR STANDING HEIGHT MEASUREMENT: See "Chevrolet Rear Suspension".*

FRONT SHOCK ABSORBER REPLACEMENT: With ¼" open end wrench, hold upper stem from turning and remove upper stem retaining nut, grommet retainer and grommet. Remove two bolts retaining lower shock absorber pivot to lower control arm and pull absorber assembly and mounting out at bottom of spring housing. Inspect rubber grommets and, if necessary, replace. To install, place rubber grommet retainer and grommet on upper stem of shock absorber and install shock absorber up through lower control arm and spring housing. Index upper stud through mounting hole in top of spring housing. Install retainer nut to upper shock absorber stem and holding stem with ¼" wrench, tighten nut until it bottoms on shoulder of stem. Tighten to 4-6 ft. lbs. torque and stake in place. Install pivot bolts through lower pivot to lower control arm and tighten securely.

SPRING REPLACEMENT (1955): Remove front shock absorber on side spring to be replaced (see above). Raise front end of car off floor and place stand jacks under frame side rails. Lower car on jacks. Remove tire and wheel assembly (*NOTE*–To avoid damage to spherical joints during spring operations). Remove four lower control arm cross shaft bushing bolts. Install Spring Compressor J-5817 through shock absorber

1955 CHEVROLET FRONT SUSPENSION

mounting hole in front cross member and through spring. Install plate, thrust washer and nut and tighten to slightly compress spring. Remove lower spherical joint cotter pin and nut. Loosen stud by hammering on side of steering knuckle joint boss, backing up steering knuckle with heavy hammer. Remove upper spherical joint stud from knuckle in similar manner, and hang drum and knuckle assembly without loading brake hose. Remove four lower control arm inner shaft-to-cross member nuts and bolts. Unscrew spring compressor nut and remove spring. To install, reverse removal procedure. Rotate spring to make certain it fits helical seats in both cross member and lower control arm.

SPRING REPLACEMENT (1956-57): Remove front shock absorber on side spring to be replaced (see above). Raise front end of car off floor and place stand jacks under frame side rails. Lower car on jacks. Remove tire and wheel assembly (*NOTE*–To avoid damage to spherical joints during spring operations). Remove four lower control arm cross shaft bushing bolts. Install Spring Compressor J-6318 through shock absorber mounting hole in front crossmember and through spring. Install nut washer and thrust bearing on Compressor shaft to keep Compressor from falling back through. Index Cross Shaft of Tool J-6318 through eye in Tool. Attach Cross Shaft to shock absorber pivot bar bolt holes in bottom of lower control arm. Use bolts from pivot bar, tighten securely. Tighten upper Compressor nut to slightly compress spring. Remove lower spherical joint cotter pin and nut. Loosen stud by hammering on side of steering knuckle joint boss, backing up the steering knuckle with a heavy hammer. Remove upper spherical joint stud from knuckle in similar manner, and hang drum and knuckle assembly without loading brake hose. Remove four lower control arm inner shaft-to-crossmember nuts and bolts. Unscrew spring compressor nut and remove spring and lower control arm. (*NOTE* - On some models generator may have to be loosened, then raised in order to compress spring compressor). To install, reverse removal procedure. Rotate spring to make certain it fits helical seats in lower control arm and crossmember.

SPRING REPLACEMENT (1958-60): Raise car on a hoist (at frame so control arms are free) and remove wheel, stabilizer bar, and shock absorber. Loosen lower ball joint to steering knuckle nut, and two lower control arm cross shaft bushing bolts. Place Tool J-6874-1 across sixth coil (approx.) and secure Tool J-6874-2 to upper shoe with capscrews and lockwashers. *NOTE - Upper shoe "V" notch and lower shoe raised land should contact spring.* Insert Tool J-6874 through center of spring and attach to upper and lower shoe assembly with bolt and nut. Place spacer under shock absorber mounting hole and against bottom of lower control arm. Install special bearing washer and Tool J-6874-5 and locate bearing against spacer and large washer against bearing. Feed screw into Tool J-6874-5 up through large washer bearing and spacer, then thread into Tool J-6874 and tighten snugly. Center shoe assembly in spring. Tighten screw to lightly compress spring, then tighten the two capscrews securing upper and lower shoes to lock these shoes to spring. Compress spring just enough to clear spring tower and remove lower ball joint to steering knuckle nut. *NOTE - It may be necessary to use pry bar to remove spring.* Disconnect lower ball joint from steering knuckle and lower control arm with spring. IMMEDIATELY release compression on spring and remove tool. *CAUTION - Clear area (people and material) from path of spring when control arm is lowered.*

LOWER CONTROL ARM (Air Suspension Cars): Removal & Installation - Remove air spring (See "*Chevrolet Air Suspension*"), then remove control arm in usual manner.

LOWER CONTROL ARM SPHERICAL JOINT, CROSS SHAFT OR BUSHINGS REPLACEMENT: Remove lower control arm (See Front Spring Removal above).

Spherical Joint Replacement: Chisel or drill heads of rivets retaining spherical joint to control arm and drive out rivets. Discard spherical joint and seal. Install new joint with flange against underside of control arm and retain joint in place with special bolts and nuts supplied with new joint. *CAUTION*– Use only alloy bolts supplied for this operation.

CONTINUED ON NEXT PAGE

1955-60 CHEVROLET (C nt.)

Cr ss Shaft r Bushing R placement: Remove bolt, lock lockwasher and collar from each end of cross shaft Install three-piece spacer of J-5888 Bushing Remover and Installer in control arm Thread a 7/16"-20 capscrew (furnished with J-5888) to bottom of threads in one end of cross-shaft Support control arm in an arbor press, on support detail of Tool J 5888 *(CAUTION*–Be sure bushing flange does not contact support) Press on capscrew until bushing is free of control arm Discard bushing Remove capscrew, insert capscrew in other end of shaft and repeat above operation To install, coat outside sleeve of bushing sparingly with a lubricant *(CAUTION*–Avoid getting lubricant on rubber bushing) With cross-shaft in control arm and three-piece spacer in place, place control arm on support Hand start bushing into control arm and over end of cross-shaft *(CAUTION*–End of shaft with greatest distance from end of shaft to bolt holes should be toward front of control arm) Install collar of Tool J-5888 over bushing Be sure three-piece spacer is not over-lapping bushing holes in control arm Press bushing into control arm until flange contacts control arm Invert arm in press, and repeat above operation on other bushing After installation, cross-shaft should be able to be rotated by hand Install collar, lockwasher, and capscrew in each end of cross-shaft but do not tighten

L w r C ntr l Arm Installation: See "Front Spring - Installation" above Tighten bushing collar bolts to 45-55 ft lbs

UPPER CONTROL ARM SPHERICAL JOINT, CROSS-SHAFT OR BUSHINGS REPLACEMENT: Support vehicle weight at outer end of lower control arm. Remove wheel and tire assembly Remove cotter pin and nut from upper control arm ball stud Loosen stud by hammering on side of steering knuckle joint boss, backing up knuckle with heavy hammer Remove two nuts retaining upper control arm shaft to front cross-member *Not numb r of shims at each bolt.* Remove upper control arm from vehicle

Sph rical J int R plac m nt: Same as spherical joint replacement for lower control arm (above), except that flange of joint is installed on topside of upper control arm and a shield is installed around joint on underside of control arm

Cr ss-Shaft r Bushing Replacement: Same as cross-shaft and bushing replacement for lower control arm, except that one-piece spacer instead of three-piece spacer of Tool J-5888 used and 3/8"-24 capscrew (furnished with J-5888) instead of 7/16"-20 capscrew.

Upper C ntr l Arm Installati n: Reverse removal procedure Tighten bushing collar bolts to 35-40 ft lbs

1955-60 CHEVROLET CORVETTE FRONT SUSPENSION

Ch vrol t Corv tt (1955-60)

DESCRIPTION: Independent, linked parallelogram type with direct acting shock absorbers and coil springs "Threaded Bushing" pivot joints used on upper and lower control arms for connection to steering knuckle. Caster and camber adjustments made by rotating upper control arm pivot bolt (eccentric)

ADJUSTMENT & PARTS REPLACEMENT: *See "1954 Chevrolet Front Suspension"*

Kingpin Inclination: 3½-4½° crosswise Not adjustable

Caster: 0° to Pos 1° (1955-56), Pos 2¼°±½° (1957-60) Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting from rear bushing at outer end of upper control arm, then insert an Allen wrench through hole and turn pivot bolt until correct caster setting secured *NOTE - Pivot bolt must be turned in full turns only for caster adjustment, otherwise camber will be changed*

Camber: 0° to Pos 1° (1955-56), Pos ½°±½° (1957-60) After adjusting caster (above), rotate pivot bolt not more than ½ turn in either direction to secure correct camber Entire range of adjustment is obtained in ½ turn of pivot bolt

Toe-In: 0-1/8" (1955-56), 1/8" (1957-60) Loosen clamps at each end of left hand tie rod and turn tie rod (right hand rod is one-piece non-adjustable type) Tighten clamp bolts to 8-12 ft lbs

Toe-Out on Turns: With outer wheel at 20°, inner wheel should be 23° Not adjustable

1955-58 Spring Application

ℂ - Dot on second coil.

1959-60 Spring Application

Type	Color Code	Part N .
Standard	ℂ	3756540
Heavy Duty	ℂ	3748140

ℂ - Gray stripe on lower 4 coils Free height is 13¾" (Std), 11 1/8" (Heavy Duty)

1958-60 CHEVROLET REAR SUSPENSION (EXCEPT CORVETTE)

Chevrolet Pass. Cars, Exc. Corvette (1958-60)

DESCRIPTION: 1958 Models - Suspension linkage consists of two lower control arms and a single upper control arm Forward ends of lower control arms are attached to brackets on frame side rails and rear ends are attached to brackets on rear axle housing Upper control arm is attached at front to inner side of both frame side rails and at rear to a bracket welded to center of rear axle housing Coil springs are mounted with lower end seated on lower control arm and upper end seated in tower bracket welded to frame side member *NOTE - With air suspension, coil springs are replaced by air springs in same location*

1959-60 Models: Suspension is similar in design to 1958 models except that lower control arm bushings are a new design and the upper control arm is connected to rear axle housing at right hand side on top of axle tube and to bracket on frame right hand side rail A tie-rod is attached to frame left hand side rail and to right hand side of rear axle housing

REMOVAL & INSTALLATION

►*REMOVAL & INSTALLATION NOTE Except where noted, following procedures apply to all models*

SHOCK ABSORBERS (Coil & Air Spring Cars): Removal - Remove lower attaching bolt, lockwasher and spacer, then remove upper two attaching nuts, bolts and washers Pull shock absorber off of lower anchor pin

Installation: Assemble two-piece bushing into eye on shock absorber, then install spacer lockwasher and nut (do not tighten) Install and tighten upper bolts, flat washers, lockwashers, and nuts, then tighten lower attaching nut

Shock Abs rber L wer Anchor Pin: R m val - *NOTE* - Remove rear coil spring (see below), or support rear suspension lower control arm Remove shock absorber from lower mounting, then remove anchor pin nut and lockwasher Install Tool J-7063, and sliding hammer J-2619, and drive pin out of rear suspension lower control arm *(NOTE* - It may be necessary to put a horizontal load on lower control arm rear bushing to keep it from flexing)

Installation: Use chalk and mark flat spot location on anchor pin threads and on corresponding flat on lower control arm bracket *(NOTE* - It is advisable to remove rear wheel to aid in alignment of these two chalk marks) Install Tool J-7063 to anchor pin and enter into lower control arm Attach sliding hammer, Tool J-2619, and drive into place, keeping the two chalk marks aligned Install shock absorber on lower mounting, then install anchor pin lockwasher and nut

REAR COIL SPRINGS: Removal - *(NOTE - For removal of rear air springs, see "Chevrolet Air Suspension")* Place car on a hoist and support it at both frame side rails. Place jack (or post of a twin post hoist) under rear axle. Remove rear shock absorber lower mounting from anchor pin, then remove nut and lockwasher from upper control arm rear pivot By using a tapered punch, tap out pivot bolt but leave punch in its place. Disconnect propeller shaft from differential and loosen center bearing support. Carefully lower rear axle housing until it or the tires (depending on type of hoist used) just hangs clear of hoist. *(CAUTION - Be careful not t damage flexible brake line)* Remove rear spring from seat. *NOTE* - In some cases it may be necessary to remove tapered punch locating control arm to pivot bushing on axle housing to permit hoist to clear axle housing Also it may be necessary to assist the springs out of their seats by using a pry bar or one "screw type" jack stand that will permit raising car frame in relation to rear axle.

Installati n: Place spring in its seat on lower control arm with end of spring not more than ½" from end of

CONTINUED ON NEXT PAGE

1958-60 CHEVROLET REAR SUSPENSION (C nt.)

pocket in seat. Raise rear axle assembly and attach lower shock absorber mounting. Connect propeller shaft to differential assembly If tapered punch was removed, tap the upper control arm to start it over the pivot bushing. Hold alignment of upper control arm and pivot bushing with a pry bar, then remove tapered punch (if installed) and install pivot bolt through upper control arm and bushing. Install lockwasher and nut but do not tighten. Position center propeller shaft bushing, then lower car to floor. Bounce rear end several times and tighten pivot attaching nut to 90 ft. lbs

REAR RIDING HEIGHT (COIL SPRING CARS): Position car on a smooth floor, then bounce and rock car several times and allow it to settle to normal height.

R ar Springs: Measure distance from top of rear axle housing to the frame kick-up. The height should be as indicated in table below. Repeat on opposite side If necessary to correct height, springs must be replaced. Springs do not have flat ends. DO NOT use shims

Taxi	3758764
Station Wgn., Exc. Kingswood (H D)	3744364
Sedan, Spt. Cpe. & Conv. (H D)	3758764

► *COIL SPRING IDENTIFICATION NOTE:* Identified by two stripes of paint as follows· 3777133 (Yellow-Orange), 3777136 (Yellow-Yellow), 3754513 (Blue-Orange), 3744364 (Coral-Yellow), 3765137 (Purple-Lime), 3758764 (Lt. Blue-Lime), 3764330 (Coral-Lime).

UPPER CONTROL ARM (1958): Removal - Use a hoist that will support rear axle housing or wheels, then remove three bolts (each side) attaching upper control arm bracket to frame bracket and remove reinforcement *(NOTE* - This reinforcement was not used on early models, when reassembling, be sure and install reinforcement, Part No 3751601, and two longer attaching bolts). Separate upper control arm bracket from frame bracket, noting the number of shims removed (these shims control driveline angles). Remove arm from car. If control arm bushings (located on axle housing and in forward ends of control arm) are to be removed, use hammer and chisel and drive point of chisel between the two inner bushing surfaces to drive them apart Tap out with a short punch. *(NOTE - On forward bushing, first remove bracket from control arm)*

Installation: *(NOTE - If necessary to replace bushings, see "Bushing Installation" below)* Place upper control arm in position on rear pivot then tap down over pivot and bushings If necessary install a tapered punch through control arm and bushing to aid in alignment. Align forward ends of upper control arm bracket with frame bracket, then install two lower bolts through each bracket assembly Make sure shims and reinforcement are in place (see "Removal" above), then install flatwashers lockwashers and nuts Install upper bolts, lockwashers and nuts with head of bolt pointing toward front of car Install rear pivot bolt through upper control arm and pivot bushing assembly and install lockwasher and nut, but do not tighten Check drive line angles *(see "Chevrolet Special Data")* Lower car to floor, then bounce car several times to settle bushings Tighten rear bushing bolt to 80-90 ft lbs , and the two upper control arm to bracket bushing bolts to 55-70 ft lbs

UPPER CONTROL ARM (1959-60): R m val - Raise car on a hoist that will support rear axle housing or wheels, then remove rear pivot bushing bolt at rear axle housing *NOTE - Rear axle must be supported in such a way as to prevent axle housing from rotating about the lower control arm rear pivot, and to also relieve load on pivot bushings* Remove bolts, lockwashers, and nuts securing upper control arm bracket to frame bracket or crossmember *CAUTION - Note number of shims removed as th y control driveline angle* Remove arm from car, then remove bolt, nut and washer attaching upper

CONTINUED ON NEXT PAGE

1958-60 CHEVROLET REAR SUSPENSION (C nt.)

control arm to bracket and separate control arm from bracket. To remove bushings, proceed as follows: With control arm bushing centered over Tool J-7574-4 and with Tool J-7574-3 in place, support arm at opposite end so it is horizontal, then press or tap bushing from arm with Tool J-7574-1 and Tool J-7079-2. Repeat procedure for opposite end of arm.

Installati n: *NOTE - If necessary to replace bushings, see "Bushing Installation" below.* Tap front of upper control arm into bracket, then install bolt, lockwasher, and nut but do not tighten. Set control arm (with front bracket installed) on axle housing bracket and tap into place. Install bolt (head of bolt must be toward outboard side), lockwasher and nut but do not tighten. Align forward end of upper control arm bracket with frame bracket or crossmember, then install two lower bolts through control arm bracket and frame bracket or crossmember. *CAUTION - Make sure shims removed at disass mbly are r installed in original locations.* Install both nuts and lockwashers. Install upper bolt and flat washer from front of bracket, then install lockwasher and nut. Tighten the three bracket bolt nuts to 60-80 ft. lbs. *NOTE - If a new control arm was installed, check driveline angle (see Chevrolet Special Data).* Lower car to floor, then bounce rear of car several times to settle bushings. Tighten upper control arm nuts to 80-90 ft. lbs.

UPPER CONTROL ARM BUSHING INSTALLATION (1958) Proceed as follows:

R r Bushing: Assemble Tool J-7055-1 to bushings and position both bushings at bracket locations. Place washer and thrust bearing on screw and insert this through bushings and tool. Install nut and draw up finger tight. Position Tool J-7055-2 between bracket flanges to prevent pivot bracket damage, then turn head of tool while turning nut to draw bushings into position. *NOTE - Check for binding during installation. Inner flanges of bushings must be flush with pivot bracket surfaces for proper installation.*

Fr nt Bushings: Assemble Tool J-7055-5 to both bushings and position both bushings at control arm locations. Place washer and thrust bearing on screw and insert this through bushing and Tool J-7055-5. Install nut and draw up finger tight. Position Tool J-7055-4 between channel flanges at bushing to prevent distortion of control arm, then turn screw to draw bushings into position. *NOTE - Check for binding during installation. Inner flanges of bushings must be flush with control arm surfaces for proper installation.* Compress bushing halves with "C" clamp and tap bracket into place. *(NOTE* - Be sure flared portion of bracket is inboard and pivot bolts are installed with head outboard). Install nut but do not tighten.

UPPER CONTROL ARM BUSHING INSTALLATION (1959-60): Proceed as follows:

Front & Rear Bushings: Turn arm to proper side (bushing can only be installed from one direction), then center bushing hole over support, Tool J-7574-4, and install Tool J-7574-3 between flanges at hole location. *NOTE- Tool J-7574-3 will prevent distorting arm during bushing installation.* Fix Tool J-7574-2 on driver handle, J-7079-2, then start bushing into hole and press or tap into place. Check to see that no interference or cocking takes place. *NOTE - Flange of bushing must be seated against arm.* Repeat procedure for opposite end of arm.

LOWER CONTROL ARMS: Removal - Place car on hoist and support frame side rails. Remove shock absorbers, then remove wheels. Remove rear springs. *NOTE* - On Air suspension units, the air spring bellows will remain in place. Remove shock absorber lower anchor pin (see above). *NOTE* - If both rear suspension control arms are to be removed, support rear axle housing to prevent its moving or falling from hoist or jack. Remove parking brake cable hold down clip, then remove attaching nut, bolt, and lockwasher on forward end of control arm and remove arm. If control arm bushings are to be removed, proceed as follows: **1958 Models** - Use Tool J-7053-1, J-7053-3, and J-5888-3 and press out old bushings. **1959-60 Mod ls** - Support control arm horizontally, then center control arm and front bushing over Tool J-7574-4, and with Tool J-7574-3 in place, press or tap bushing from arm with Tool J-7574-5 and J-7079-2. *NOTE - Be sure to place remover tool on end of bushing without the flange.* To remove rear bushing, repeat the above operation on opposite end of arm using Tool J-7574-1 in place of Tool J-7574-5.

Installation: If bushings were removed, proceed as follows: **1958 Models** - Use Tools J-7053-2, J-7053-3 & J-5888-3 to press bushings into control arm. **1959-60 Models** - To install front bushing, fix Tool J-7574-6 onto driver handle, Tool J-7079-2, then start bushing into hole and press or tap into place. Check to see that there is no interference or cocking and make sure bushing flange is seated against arm. To install rear bushing, repeat the above operation using Tool J-7574-2 in place of Tool J-7574-6. **1958-60 Models** - Install forward end of control arm but do not tighten bolt. Swing control arm into place and install shock absorber lower anchor pin, but do not tighten attaching bolt. Install wheel, then install coil springs (see above), and shock absorber. Check drive line angle *(see Ch vrolet Special Data).* Lower car to floor and bounce it several times to settle bushings, then tighten all attaching nuts to 80-90 ft. lbs.

REAR SUSPENSION TIE-ROD (1959-60): Removal - Remove nut, washer and bolt from left hand side, and nut and washer from stud on right hand side that secures tie-rod to brackets, then remove tie-rod.

Bushing Replacement - With tie rod centered over Tool J-7877-2 and with tie rod supported horizontally, press or drive bushing from rod, using Tool J-7877-1 and J-7079-2. With tie rod centered over Tool J-7877-2 and rod supported horizontally, press or drive bushing into arm using Tools J-7877-3 and J-7079-2. *NOTE - To l J-7877-2 should bottom on rod when bushing is fully seated.*

Installation - Mount tie rod to right hand stud, then install nut and special washer but do not tighten. Install bolt, lockwasher and nut to left hand bracket but do not tighten. Lower car to floor and bounce rear end several times, then tighten nuts to 55-70 ft. lbs.

1960 CHEVROLET TRUCK FRONT SUSPENSION

Ch vr l t Trucks (Exc. Fwd. Cont. & 4-Whl. Dr.) (1960)

DESCRIPTION: 10, 20, 30, 40 Series - Front end of each torsion bar is supported in a steel tube in lower control arm and is held in position in hexagon section of tube. Rear end of torsion bar is supported in an adjustable anchor connected to a special crossmember. Upper end of each shock absorber is bolted to a frame bracket and lower end is bolted to lower control arm.

50, 60 S ri s: Front end of each torsion bar is supported in hexagon section of upper control arm. Rear of torsion bar is supported in a bracket attached to outside of frame side rail and is held by hexagon portion of bracket. A pin which passes through the bracket and a notch in torsion bar rear hex locates and locks the bar in position. Shock absorbers are connected between front crossmember and lower control arm.

ADJUSTMENT: *NOTE - Truck curb height must be checked and corrected before making camber and caster adjustment.*

Truck Curb Height: 10, 20, 30, 40 Series - 4½" measured from bottom edge of crossmember to top outer flange of lower bumper bracket at centerline of spindle. Adjust torsion bar rear anchor to obtain correct height.

50, 60 Series - 5 1/16" measured from bottom edge of crossmember to top outer flange of lower bumper bracket at centerline of spindle. No adjustment provided. If dimension not correct, replace torsion bars.

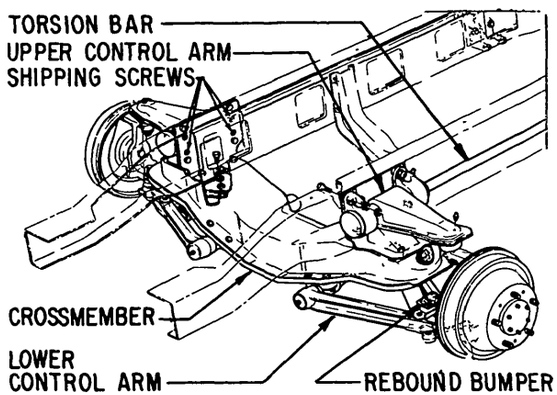
Caster (10, 20, 30, 40 Series): Pos. 1°±½°. *NOTE - Change shims between upper control arm spacer and bracket at eith r fr nt or r ar bolt.* One .0299" shim added to rear bolt changes caster a **minus** 24' and camber a **minus** 1'. One .0299" shim removed from rear bolt changes caster a **plus** 24' and camber a **minus** 2'. *NOTE - .0598" and .1196" shims are available to reduce the number of shims.* The shim pack at each bolt location should not exceed 5/8" (twenty-one .0229" shims). The total difference in shims between front and rear bolts should not exceed .33" (eleven .0299" shims).

Caster (50, 60 Series): Pos. 2½°±½°. *NOTE - Cast r adjustments are made by changing location of low r control arm shafts with reference to notched plat s welded to crossmember.* Check caster to determine amount of change required to obtain Pos. 2½°±½° caster, then mark location of control arm shaft with reference to notched attaching plate. Loosen four shaft-to-crossmember bolts to free shaft from notches in attaching plates, then move shaft rearward to decrease caster or forward to increase caster. *NOTE - Moving shaft a distanc f on notch chang s cast r approximat ly* ½°. Tighten bolts and recheck adjustment.

CONTINUED ON NEXT PAGE

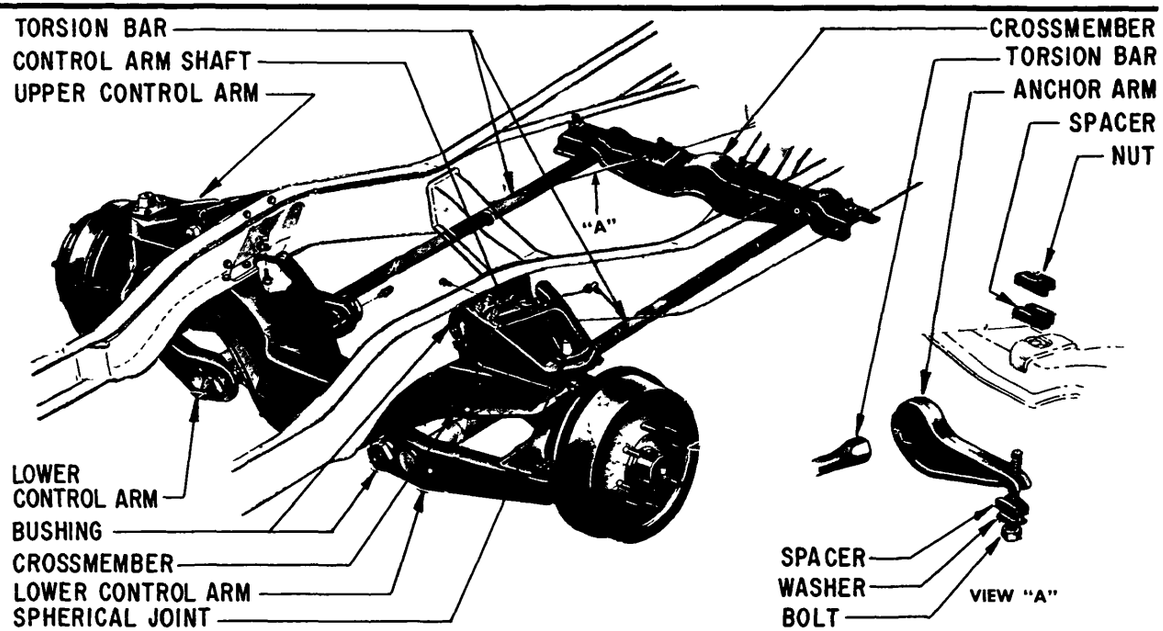
CHEVROLET TRUCK FRONT SUSPENSION (C ntinu d)

Camb r (10, 20, 30, 40 S ri s): Pos. ½°±½°. *NOTE - Change shims between upper control arm spacer and bracket at both front and rear bolts equally.* One .0299" shim added or removed from both bolts changes camber 10'38". Removing shims decreases camber. Adding shims increases camber. *See "Caster" above for available shim thickness and total thickness of shim packs.*



Camber (50, 60 Series): Pos. ¾°±½°. *NOTE - Change shims between upper control bracket and support at both front and rear bolts equally.* One .0299" shim added or removed changes camber approximately ½°. Adding shims increases camber. Removing shims decreases camber. *CAUTION - Make sure that the Phillips type screws (installed during manufacture) located in upper control arm brackets have been removed and discarded. These screws are needed during plant assembly only.* Remove two upper nuts and bolts attaching control arm bracket to frame and loosen two lower nuts. Lift truck at front crossmember until control arm bracket can be pried away from support. Insert or remove shims as required.

►*UPPER & LOWER CONTROL ARM SHAFT & BRACKET NUT TIGHTENING SPECIFICATION CAUTION:* These nuts must be tightened to the following specifications: **Lower Control Arm Shaft Nuts** - 90-115 ft. lbs. (10, 20 Series); 100-135 ft. lbs. (30, 40 Series); 180-240 ft. lbs. (50, 60 Series Exc. H.D.); 315-420 ft. lbs. (50, 60 Series H.D.). **Upper Control Arm Shaft Nuts** - 60-75 ft. lbs. (10 Series); 85-110 ft. lbs. (20 Series); 120-155 ft. lbs. (30, 40 Series). **Upper Control Arm Bracket Nuts** - 125-165 ft. lbs. (50, 60 Series).



T e-In: 1/8"-1/4". Loosen clamp bolts at ends of each tie rod and turn tie rod until proper toe-in is secured and steering gear is on "high point" for straight ahead travel.

Steering Axis Inclination: 8° (10, 20, 30, 40 Series); 6°53' (50, 60 Series). All at 0° camber.

SHOCK ABSORBERS: 10, 20, 30, 40 Series (Removal) - Remove upper bolt at frame bracket, then remove lower pivot nut and washer from inside lower control arm. Remove shock by pulling rearward out of control arm.

CHEVROLET TRUCK FRONT SUSPENSION (50, 60 SERIES)

CHEVROLET TRUCK FRONT SUSPENSION (10, 20, 30, 40 SERIES)

Installation - Insert shock absorber pivot in rear of lower control arm, install opposite end in bracket on frame and install bolt, lockwashers and nuts. Tighten nuts to 65-85 ft. lbs. (upper); 40-50 ft. lbs. (lower).

50, 60 Series (Removal): Remove nuts from mounting bolt at front of crossmember support and lower ball stud arm. Drive out bolts and remove shock absorber.

Installation - Position eye at large end of shock absorber inside crossmember support from below, then align eye with holes in support and install bolt through support and eye from rear of support. Install nut and tighten to 75-90 ft. lbs. Align lower end of shock absorber with hole in ball stud arm, then install bolt (from rear) and nut. Tighten to 95-115 ft. lbs.

TORSION BARS: *CAUTION - Torsion bars are furnished as right and left parts and must be installed on correct side of truck so proper curb height can be obtained. New bars are identified by colored bands located 6" from rear hex, one band indicating right hand bar and two bands indicating left hand bar. When handling bars, be careful to prevent nicks or scratches. Nicks or scratches may cause failure of bar in operation. When a torsion bar is replaced, front end alignment must be checked.*

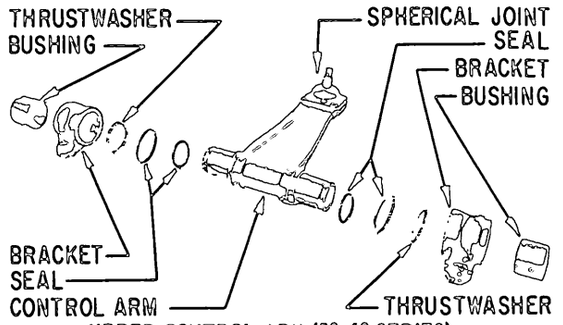
Removal (10, 20, 30, 40 Series): Remove upper control arm bumper from control arm, then raise truck and support frame so control arms are at full rebound position Back off adjusting bolt to unwind torsion bar, until bolt and lower spacer can be slipped out of anchor arm, then pull anchor arm rearward off bar. Pull torsion bar rearward out of front socket.

Installation (10, 20, 30, 40 Series): With front suspension control arms in full rebound position (rebound bumper not installed), install front hex of torsion bar into rear of torsion bar socket in lower control arm and slide forward until bar stops against dimple in socket (this locates fore and aft position of torsion bar). Locate torsion bar anchor spacer and nut so rocker groove of spacer and ridge of nut (long sides of spacer and nut) are parallel to crossmember. Install special washer and lower spacer on bolt, then insert bolt up through crossmember and upper spacer and start into nut. Assemble torsion bar arm to rear hex of torsion bar so spacer and bolt can be slipped into arm when bolt engages about half the threads of the nut. Position arm to bar so rear face of arm is flush with rear of bar (within 1/32"). Check position of spacer and nut to be sure the rocker surfaces are parallel to crossmember, then tighten torsion bar adjusting bolt on each side until truck is at normal curb height: *NOTE - Right and l ft hand adjustments can be made consecutiv ly or simultan lusly.* Install rebound bumper.

Removal (50, 60 Series): Remove rebound bumper and remove shock absorber bolt from lower ball stud support. Remove weight from front suspension by jacking frame until upper control arm contacts crossmember. Drive lock pin up out of torsion bar rear bracket, then pull torsion bar to rear and out of control arm hex and bracket box. Pull torsion bar out through rear bracket. *NOTE - On short wheelbas mod ls, or oth r mod ls with special equipment that limits cl aranc for r arward removal of torsion bar, proc d as follows:* Pull bar forward to remove rear hex from rear bracket, then loosen upper control arm bracket nuts and pull control arm out far enough so torsion bar can clear outside of rear bracket. Pull torsion bar rearward to remove front hex from control arm. Tilt bar and remove through wheel opening. Another method to remove torsion bar is to pull bar to rear to remove hex from upper control arm, then remove upper control arm bracket bolts and swing control arm rearward around ball joint. Pull torsion bar forward to remove rear hex from rear bracket. Tilt bar downward and out forward end of truck.

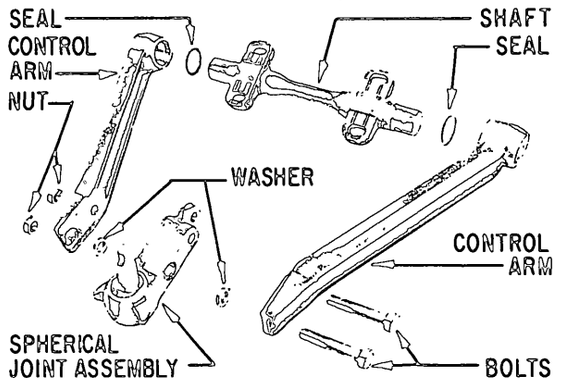
CONTINUED ON NEXT PAGE

1960 CHEVROLET TRUCK FRONT SUSPENSION (Continued)



Installation (50, 60 Series): Pass forward end of bar (end not notched) through bracket and place adjacent to control arm. Align notched corner on rear hex of bar with drilled corner of bracket hex, then slide bar into control arm and bracket hexes. Align notch in bar with lock pin hole in bracket and start lock pin into top of hole, then drive pin in flush with surface. Allow weight of truck to rest on suspension and lubricate control arm. Install shock absorber lower mounting bolt and rebound bumper. *NOTE - On truck models requiring the use of special removal procedure, reverse the removal procedure for installation.*

Torsion Bar Application & Identification



Truck Series	Right Bar	Left Bar	①Ident.	Length
10 (Std.)	3753876	3753875	White	45.70"
10 (H.D.)	3766852	3766851	Red	45.70"
20 (Std.)	3766852	3766851	Red	45.70"
20 (H.D.)	3753878	3753877	Green	45.70"
30 (Std.)	3763502	3763501	Blue	45.70"
30 (H.D.)	3766854	3766853	Yellow	45.70"
40 (Std.)	3766854	3766853	Yellow	45.70"
40 (H.D.)	3766856	3766855	Orange	45.70"
50 (Std.)②	3773110	3773109	White	57.96"
50 (H.D.)②	3773112	3773111	Green	57.96"
50,60 (Std.)③	3773116	3773115	Green	70.45"
60 (Std.)②	3773112	3773111	Green	57.96"
60 (H.D.)③	3773118	3773117	Yellow	70.45"
60 (Std.)④	3773118	3773117	Yellow	70.45"

① - New bars are identified by colored bands located 6" from rear hex, one band indicating right hand bar and two bands indicating left hand bar.
② - Except School Bus Chassis.
③ - With School Bus Chassis.
④ - With 243" Wheelbase School Bus Chassis.

SPHERICAL JOINT: Inspection (All Models) - The spherical joint on the control arm which does not carry the torsion bar (10, 20, 30, 40 Series upper; 50, 60 Series lower) can be checked as follows: Support frame and separate torsion bar from control arm (*see "Torsion Bar" above*), then loosen spherical joint stud nut. Release stud by rapping sides of steering knuckle at flats adjacent to stud, then remove nut, separate stud from knuckle and remove rubber seal. Install stud nut and measure torque required to turn stud in joint assembly. Torque should be at least 2 ft. lbs. (10, 20, 30, 40 Series); 5 ft. lbs. (50, 60 Series). If excessive wear is indicated on this joint, both upper and lower joints should be replaced. *NOTE - Maximum allowable torque, with joint well lubricated, should be 15 ft. lbs. (10, 20, 30, 40 Series); 20 ft. lbs. (50, 60 Series).* If the spherical joint as outlined above is in good condition, inspect joint on control arm which carries the torsion bar (10, 20, 30, 40 Series lower; 50, 60 Series upper) as follows: With joints, control arms and steering knuckles completely installed, support truck weight on wheels or wheel hubs. Use an outside micrometer or caliper and measure distance between end of lube fitting and end of ball stud. Record this dimension. Repeat the procedure on opposite side of truck. On 10, 20, 30, 40 Series, support truck weight at outer end of each lower control arm so wheels are free. On 50, 60 Series, support truck at center of crossmember to let wheels hang free. Again measure the distance between end of lube fitting and end of ball stud. If the difference in dimensions on either side is greater than 3/32", the joint is excessively worn and joints at both sides of truck should be replaced. If measurements do not indicate worn joints, check torque tightness of stud nut at each side as follows: Clean nut and cotter pin and check for evidence of looseness of stud in knuckle. If looseness is not indicated, mark stud and nut to identify relative location, then back off stud nut and retighten to original position. Note the torque reading required to tighten nut. If less than 45 ft. lbs., stud may have been loose in knuckle and should be replaced.

UPPER CONTROL ARM (50, 60 SERIES)

LOWER CONTROL ARM (50, 60 SERIES)

Replacement (10, 20, 30, 40 Series Upper & Lower & 50, 60 Series Upper): With control arm assembly removed from truck, cut rivet heads with a chisel and knock out the rivets. Install new joint on arm and secure with bolts and nuts furnished with service replacement joint. Tighten nuts to 13-19 ft. lbs. (10, 20 Series upper); 18-24 ft. lbs. (30, 40 Series upper); 40-55 ft. lbs. (7/16" bolts); 65-85 ft. lbs. (½" bolts). *CAUTION - Use only alloy bolts furnished for this installation.*

Replacement (50, 60 Series Lower): Remove two joint-to-arm bolts, then spread front and rear arms and remove joint assembly. Remove special washers from joint casting or control arms. Insert joint between ends of arms and install special washer in bolt hole counterbore in each arm. Install bolts and nuts and tighten securely.

CONTROL ARMS: Removal (All Models) - Support frame and separate torsion bar from control arm (*see "Torsion Bars" above*). Loosen spherical joint stud nut, release stud by rapping sides of steering knuckle at flats adjacent to studs, then remove nut, separate stud from knuckle and remove rubber seal. *NOTE - When removing lower control arm on 50, 60 Series, mark location of shaft with reference to attaching plate on crossmember to aid in adjustment when installing control arm.* Remove nuts from mounting bolts at frame or crossmember and lift the assembly from truck. When removing upper control arm, remove and tag shims for use when installing control arm.

Shaft, Bushing and/or Seal Replacement (10, 20, 30, 40 Series Upper & Lower Control Arms): Unscrew bushing from control arm and shaft at each end of shaft and remove shaft. Slide seals off shaft. To reassemble, slide new seal on each end of shaft and insert shaft through openings in control arm. Start new threaded bushings on shaft and into control arm. Turn shaft until it is centered between edges of control arm, then turn bushings in until inner surface of hex bottoms on outer edge of control arm. Tighten bushings to 170-190 ft. lbs. (10, 20 Series upper); 200-220 ft. lbs. (10, 20 Series lower); 200-220 ft. lbs. (30, 40 Series upper); 240-260 ft. lbs. (30, 40 Series lower). Check shaft for free rotation.

Lower Spherical Joint, Control Arm, or Shaft Replacement (50, 60 Series): Remove nuts from joint-to-arm bolts and remove bolts, then spread front and rear arms and remove joint assembly. Remove special washers from joint casting or arm. Unscrew arms from each end of shaft and remove "O" ring seals. To reassemble, lubricate new "O" ring seals and install one in bore in each arm. Carefully start threads into arm to avoid damage to "O" ring seal. Turn arm until threads bottom, then install "O" ring seal in other arm and install arm on shaft in same manner. Back off each arm a minimum of 1/8 turn, then an additional amount necessary for both arms to point in same direction. Place arm and shaft assembly on bench with notches in shaft facing upward. Insert joint between ends of arms and install special washer in bolt hole counterbore in each arm. Install bolts and nuts and tighten to 40-55 ft. lbs. (7/16" bolts); 65-85 ft. lbs. (½" bolts). Check shaft for free rotation.

Upper Control Arm, Brackets & Bushings (50, 60 Series): Pull mounting brackets off ends of control arm and remove "O" ring seals and thrust washers from brackets and control arm. To replace bushings in brackets, remove old bushings, then start new bushing straight in bore in bracket so open end of lubricating grooves in bushing inner diameter face into bracket. Press bushings into bottom of bore in bracket with an arbor press. Install "O" ring seal in groove at each end of control arm, then install thrust washer in counterbore of each bracket and install large "O" ring seal in groove in each bracket. Slide brackets onto control arm, using care to avoid damaging seals.

Installation (All Models): Install mounting bolts on truck and on 10, 20, 30, 40 Series upper control arms, install spacers on bolts so flat side of spacer faces outside of frame. Place control arm assembly in position on truck and install mounting bolts loosely. On upper control arms, install same shims that were removed. On 50, 60 Series lower control arms align notches on shaft and attaching plate with marks made

CONTINUED ON NEXT PAGE

1960 CHEVROLET TRUCK FRONT SUSPENSION (Continu d)

before removal. On all models, tighten mounting bolt nuts to following specifications: **Lower Control Arm Shaft Nuts** - 90-115 ft. lbs. (10, 20 Series); 100-135 ft. lbs. (30, 40 Series); 180-240 ft. lbs. (50, 60 Series, exc. H.D.); 315-420 ft. lbs. (50, 60 Series, Heavy Duty). **Upper Control Arm Shaft Nuts** - 60-75 ft. lbs. (10 Series, 7/16" bolt); 85-110 ft. lbs. (20 Series, ½" bolt); 120-155 ft. lbs. (30, 40 Series. 9/16" bolt). **Upper Control Arm Bracket Nuts** - 125-165 ft. lbs. (50, 60 Series). Install rubber seal on spherical joint and insert stud through steering knuckle. Install nut and tighten to 100-135 ft. lbs. (10, 20 Series, upper); 175-250 ft. lbs. (30, 40 Series, upper & All Series, lower). Install torsion bar.

FRONT SUSPENSION UNIT & WHEEL HUB ASSEMBLY: *NOTE* - If extensive overhaul is necessary to front suspension, the complete unit can be removed and installed as follows:

Removal: Separate both torsion bars from control arms, then support engine and remove front engine mount center bolt. Separate main brake feeder line from crossmember tee. On 10, 20, 30, 40 Series, remove bolts retaining crossmember hangers to frame side rails. On 50, 60 Series, support hub and drum and remove bolts retaining upper control arms. Remove bolts securing crossmember to frame side rail lower flange and lower the assembly from vehicle.

Installation: Jack crossmember into position under frame and install frame side rail lower flange mounting bolts. On 50, 60 Series, secure upper control arm brackets to frame side rails and tighten nuts to 185-235 ft. lbs. On 10, 20, 30, 40 Series, install bolts securing crossmember hanger to frame and tighten nuts to 60-80 ft. lbs. Position engine on front mount and install mounting bolt. On 50, 60 Series, tighten to 70-85 ft. lbs. On 10, 20, 30, 40 Series, tighten to 40-50 ft. lbs. Install torsion bars, then connect front brake main feeder line and bleed brakes. Check and adjust front end alignment.

1960 CHEVROLET TRUCK REAR SUSPENSION

Chevrolet Trucks, Series 10 & 20 (1960)

DESCRIPTION: Two link suspension system with a control arm attached between each end of rear axle housing and central area of frame. A single "U" bolt attaches each control arm to axle housing and a rubber bushing is used to connect forward end of each arm to a bracket on a frame between side rails and tunnel. A pigtailed coil spring is seated and clamped between each control arm and frame forward of the rear axle. Shock absorbers are installed between brackets welded to the frame and brackets held beneath rear of each control arm. A rubber bushed tie rod parallel to axle housing is attached between right side of axle housing and frame left side rail.

SHOCK ABSORBERS: Replacement - Remove shock absorber pivot bolt nuts and washers, pull bolts and remove shock absorber from truck. To install, position eye at large end of shock absorber in frame bracket or crossmember, then install bolt, washer and nut. Align opposite end of shock absorber with anchor bracket at axle. Install bolt, washer and nut and tighten upper and lower nuts to 19-25 ft. lbs.

TIE ROD: Removal - Remove nuts and bolts from each end of tie rod and remove rod from truck.

Inspection: Check rod for deformation by sighting down its length or with a straightedge. Minor defects may be removed by bending. Replace bushings if damaged

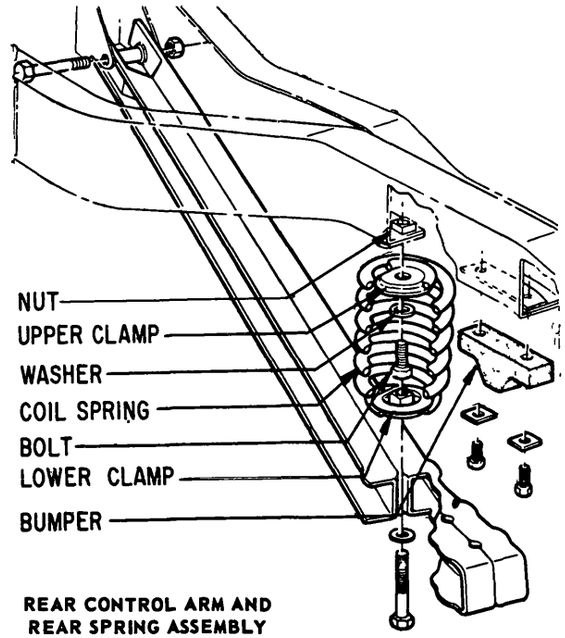
Bushing Replacement: Support end of rod on a suitable support, then index pin end of Tool J-8518-2 in center hole of bushing. Use Tool J-7079-2 and an arbor press and press bushing from rod. Position a new bushing on rod, then use Tool J-8518-1 and an arbor press and press bushing into rod eye until tool contacts rod.

Installation: Position rod ends in mounting brackets at frame and axle, lining up holes with a drift, then insert bolts and install nuts finger tight. Let weight of unloaded truck rest on suspension and tighten pivot nuts to 55-70 ft. lbs.

CONTROL ARM: Removal - Remove load from springs by jacking up frame, then remove parking brake cable from control arm bracket. *NOTE - Mark position of notch in spring clamp in relation to end of spring so it may be reinstalled in the same position.* Remove spring clamp bolt from underside of control arm, then remove "U" bolt nuts and separate shock absorber bracket from control arm. Separate control arm from "U" bolt and lower rear of control arm. Remove pivot bolt and remove control arm from truck.

Bushing Replacement: Insert Tool J-8448-3 in fork of control arm, astride bushing, then rest bushed end of arm on Tool J-5888-3 with bushing flange centered in tool. Place Tool J-8448-2 on top of bushing, indexing pin of tool in center hole of bushing. Use Tool J-7079-2 and an arbor press and press bushing from arm. To install bushing, support arm in same manner as when removing bushing, then center a new bushing with flanged side up over control arm hole. Place Tool J-8448-1 on top of bushing. After seating bushing in tool, press bushing into arm until flange contacts arm wall.

Installation: Position bushed end of control arm in pivot yoke between tunnel and frame, align holes with a drift and insert pivot bolt. Tighten nut on bolt finger tight. Position clamp inside spring so notch in clamp is in original position as marked at removal, and so it seats freely on spring end without hanging up. Raise control arm to the spring, then pass bolt, with flat washer installed, up through control arm and clamp. Install lockwasher and nut and tighten to 40-50 ft. lbs. Place arm adjacent to axle, then install "U" bolt over axle and through holes in arm. Place shock absorber bracket on ends of "U" bolt and tighten nuts to 175-250 ft. lbs. Install parking brake cable in control arm fitting and slide rubber cover into position on conduit. Lower truck to put full weight of unloaded truck on front and rear suspension, then tighten control arm pivot bolt nuts to 175-250 ft. lbs.



COIL SPRINGS: Removal - Remove shock absorber bolt from mounting bracket on axle, then remove truck weight from rear suspension by jacking up frame and adjust axle-to-frame height so that spring is relaxed or very slightly compressed. *NOTE - Mark position of notch in spring lower clamp in relation to end of spring so it may be reinstalled in its original position.* Remove upper and lower clamps from spring by backing out lower bolt from underside of lower control arm, and upper bolt from inside spring. Lower control arm sufficiently to permit removal of spring.

Installation: Place spring clamp inside spring, then position clamp in its original position as marked at removal so it seats freely on spring without any hang up. Pass clamp bolt with washer up through hole in control arm and hole in clamp, then install nut, but do not tighten. Position upper clamp inside spring and secure to frame with bolt and washer. Connect shock absorber to bracket at axle and tighten to 19-25 ft. lbs. Tighten spring clamp bolts to 40-50 ft. lbs.

Rear Spring Application

Series	Part No.
10, exc. 4-Whl. Drive (Std.)	3762207
20, exc. 4-Whl. Drive (H.D.)	3762263

REAR CONTROL ARM AND REAR SPRING ASSEMBLY

1954-56 CHRYSLER, DE SOTO, DODGE, PLYMOUTH

All Models (1954-56)

►CHANGES & CORRECTIONS

DESCRIPTION: *Independent "Parallelogram" type with coil springs.* **1955-56 Models have shock absorbers mounted inside coil springs.**

CHECKING & ADJUSTMENT: Before adjustments made, check wheel and tire balance and run-out, front wheel bearing adjustment and king pin bushing clearance, steering gear adjustment, and shock absorbers. See that springs and shock absorbers in normal position (grasp bumper and work front end of car up and down several times). Then check following points first:

Front Spring Height: With car on level floor, tires inflated to recommended pressure, measure vertical distance from inner and outer ends of lower control arm to floor (center of control arm pin at outer end, center of grease fitting in control arm pivot bar on inner end). See table below for allowable variations. Make measurements at right and left sides of car and compare. If the measurements differ more than ¼", check each front spring for correct installation at top and bottom. If springs are correctly installed and measurements made at left and right sides still differ by more than ¼", insert spacers at top of spring between seat and silencer. *If more than two spacers required to make correction for a spring, replace spring.* If measurements taken above for allowable difference as shown in table below are not within limits, check rear end of car for unequal spring heights by measuring from spring plate to frame on each side (front spring height will be affected if rear spring heights differ more than ¾").

►*NOTE:* In the following table a plus (+) sign indicates the inner end of lower arm is higher than outer end and a minus (-) sign indicates that it is lower.

CHRYSLER	Allowable Difference
1954-55 C62, C67 (Exc. 8 Pass.)	+1¼" to -¼"
1954-55 C62, C67 (8 Pass.)	+¾" to -¼"
1954-55 C63, C68 Sedan & Coupe	+1" to -0"
1954-55 C63, C68 Town & Country	+1¼" to -¼"
1954-55 C63, C68 8 Pass.	+¾" to -¼"
1954-55 C64, C69	+0" to -1"
1954-55 C66, C70	+¾" to -¼"
1955 C300	+1¼" to -¼"

1954 Sta. Wgn. & 8 Pass. Sed.	+¾" to -¼"
1955 6 Pass, Sed, & Cpe.	+1" to -0"
1955 Station Wagon	+1¼" to +¼"
All (Exc. S23 Sta. Wgn.)	+1" to —0"
S23 Sta. Wgn.	+1¼" to +¼"

DODGE	Allowabl Diff rence
1954 (All Models)	+1¼" to +¼"
1955 D55, D56 (Exc. Suburban)	+0" to -1"
1955 D55, D56 Suburban	-½" to -1¼"
All (Exc. Suburban)	+0" to —1"
Suburban	-¼" to —1¼"

PLYMOUTH	Allowable Difference
All Models	①

①—No allowable variation given. Follow procedure as given above (except for allowable variations).

Tire Inflation (1954-56): Check and inflate tires to 24 lbs. (Cold), 27 lbs. (Warm) on all models before checking front end alignment.

Kingpin Inclination

1954-55 (Exc. Chrysler C53, 59, 66, 67, 70)	5-6½°
1954-55 (Chrysler C53, 59, 66, 70)	6½-8°
1955 (Chrysler C67)	5½°
1956 (Chrysler C70)	7°
1956 (Chrysler Other Models)	5½°
1956 (DeSoto & Plymouth)	5-6½°
1956 (Dodge)	5½°

Caster: *NOTE - All Models set alike.*

1954 (Chrysler & DeSoto) - Neg. 2° preferred. Limits Neg. 1° to Neg. 3°.

1954 (Dodge & Plymouth) - 0° preferred. Limits Neg. 1° to Pos. 1°.

1955-56 (All Cars) - Neg. 2° to 0° (Neg. 2° preferred with manual steering, 0° preferred with power steering). Left side should be 0° to ¾° greater than right side within these limits.

To Adjust - Caster controlled by distance knuckle support upper pivot pin bushing (eccentric camber adjustment) turned in on upper control arm. *See Camber Adjustment.*

Camber (1954): Neg. 3/8° to Pos. 3/8°. *See Note.*

1955 (Chrysler & Plymouth) - Neg. 1/8° to Pos. 5/8° (Left side Pos. ½°, Right side 0° preferred).

1955 (DeSoto & Dodge) - Pos. 1/4°±3/8° (Left side Pos. ½°, Right side 0° preferred).

1956 (Chrysler, DeSoto, Dodge) - Pos. 1/4°±3/8° (Pos. ½° on left, 0° on right preferred).

1956 (Plymouth) - Neg. 1/8° to Pos. 5/8° (Neg. 1/2° on left, 0° on right preferred).

►*NOTE: 1954-55 Cars. Camber on left side of car should be ¼-½° greater than right side of car.*

►*TOOL NOTE:* Special tool (narrow wrench designed to fit between knuckle support and upper control arm fork so as to engage eccentric bushing) must be used for camber adjustment. Tool No. C-829 (1 7/16"), C-830 (1½"), or MT-269 (1 5/16") are used with any standard ½" square socket wrench extension.

To Adjust—Loosen clampscrew in upper end of knuckle support, turn eccentric bushing in upper end of knuckle support not more than ½ revolution from place where correct caster is secured (bushing eccentric and entire range of adjustment secured in ½ turn). Bushing must not be turned so as to bind on upper control arm.

►*CAUTION:* Bushing must not be turned so as to bind against either side of upper control arm (keep bushing centered in control arm as nearly as possible).

►*ADDITIONAL RANGE OF ADJUSTMENT:* If correct camber cannot be secured by turning eccentric bushing within limits given above, not more than two spacer shims can be installed at top of each front spring. Each shim will increase camber approximately ½°.

Toe-In (1954-55): 0" preferred. Limits 0" to 1/16" (Exc. 1954-55 Plymouth), 1/8" (1954-55 Plymouth).

(1956) 3/32-5/32" (3/32" preferred on Dodge, 1/8" preferred on all others).

Check toe-in with wheels turned to straight ahead position, measure between center of tire treads hub high, at front and rear of wheels.

To Adjust—Loosen clamp bolts on each tie rod (long rod right side, short rod left side, or both rods of equal length), turn both tie rods equally. Make certain that ball studs at each end of rod are against same side (to permit angular rotation of rod on ball studs when making turns), and see that clamp bolt on inner (left) end of long tie rod is beneath the rod (to prevent interference on turns).

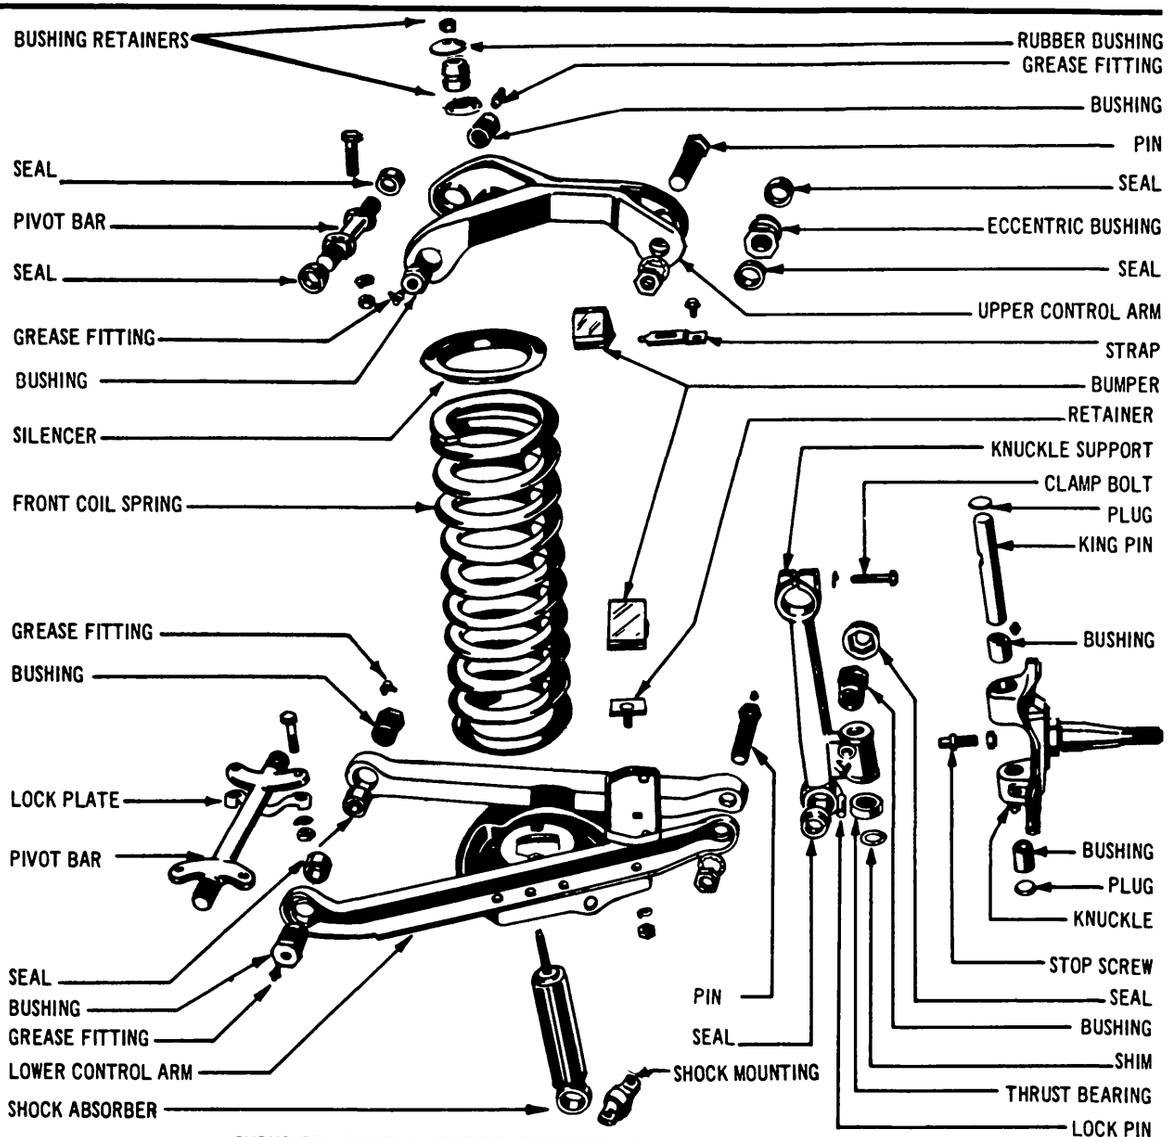
Toe-Out on Turns: (All Models)—With outer wheel turned **20°, inner wheel should be turned 21½°±1° (Exc. 1956 Plymouth). 1956 Plymouth - With inside wheel at 20°, outside wheel should be 17½-19°.**

OVERHAUL: Steering Knuckle & Kingpin Bushings—To remove, remove wheel and hub assembly. Block brake pedal so it cannot be depressed, then remove nuts and bolts that fasten brake support to steering knuckle, remove steering knuckle arm from steering knuckle. Remove brake hose and connections, lift off brake support. (*CAUTION*—Do not allow brake support and shoe assembly to be supported by flexible brake hose). Remove kingpin locking pin. Drive a punch into upper steering knuckle welch plug and pry out of steering knuckle. Drive kingpin downward, forcing out lower welch plug. (*NOTE*—A soft brass drift should be used when driving against head of kingpin). Remove steering knuckle upper bearing or bushing with Tool C-328. Remove steering knuckle lower bushing with same tool if of stationary type (See Note below). Install new lower bushing and line-ream with special tool using pilot in place of upper bearing (When upper bushing not used). If upper bushing used, install bushing from top making sure slot or identification line is between outer end and grease fitting and line-ream both bushings at same time. Install upper bearings from top with trade mark at top and oil hole in bearing lined up with oil hole in steering knuckle. Lower bushings should be installed with oil hole in bushing lined up with oil hole in steering knuckle (*NOTE*—On cars equipped with Power Steering and Disc Brakes, kingpin bushings should be installed with open end of oil groove leading toward "O" ring seals).

Upper Control Arm & Bushings: Install as follows: Use new bushings when installing pivot bar and use special spreader tool C-608 to maintain correct control arm spread while bushing being installed. Install pivot bar (with seal on each end of bar) in control arm, install spreader tool on inner ends of control arm and bolt pivot bar to tool using two capscrews and

CONTINUED ON NEXT PAGE

1954-56 CHRYSLER, DE SOTO, DODGE, PLYMOUTH (C nt.)



nuts. (*CAUTION*—Spreader tool has two sets of mounting holes to accommodate all sizes of pivot bars—make certain that correct holes used). Make certain that spreader tool jaws seat firmly against inner faces of control arm ends, expand tool until it is just snug against inside of the control arm. Start bushings on both ends of the pivot bar, lubricate bushings with tapping compound or other suitable lubricants (bushings cut own threads), turn bushings in until shoulder of bushings contact surface of control arm on car. With pivot bar correctly installed, only a moderate grip should be required to turn it. To correct slight centering error, the pivot bar may be rotated one turn in either direction.

Knuckle Support Upper Pivot Pin—Consists of a bolt threaded through both eyes of upper control arm from rear with nut on forward end. Seals are installed on pin at each side of eccentric bushing which is threaded on pin within control arm fork (bushing is clamped in upper end of knuckle support by clampscrew). With pin installed, over-all width of control arm fork (from front face of front eye to rear face of rear eye) should be 3 1/8" on all models. Eccentric bushing should be centered in fork on all models.

Lower Control Arm & Bushings: Control arms and spring seat are riveted assembly. Bushings at inner end (frame connection) are self-threading type and new bushings should be used when a new control arm assembly is installed as follows:

Control Arm Pivot Bar Bushings—(*NOTE*—Due to relocation of lower control arm pivot bar mounting bolt locations beginning 1955, Tool C-594 cannot be used for centering lower pivot bar, but can be used to maintain set dimensions of control arm. On 1954 models, tool can be used to center the bar). Install dust seals on pivot bar and position bar in control arm. Assemble Tool C-594 to bar. (*NOTE*—When Tool C-594 used on **1955-56 models, remove guide studs from tool**). **Lubricate self-threading bushings with light oil, start on both ends of pivot bar, thread into control arm until shoulders of bushings contact. Torque to 165 ft. lbs.** minimum (1954), 180 ft. lbs. minimum (1955-56). Check **pivot bar for free movement.** *NOTE* - **Rotating pivot bar will change setting. On the 1955-56 models** bar can be rotated one turn in either direction to correct a slight centering error. For correct centered position of arm as measured from rear face of arm to centerline of rear pivot bar mounting hole, see table below.

Knuckle Support Lower Pivot Pin & Bushing—Tighten pin nut to 100 ft. lbs. minimum. Install bushing in knuckle support (head to rear), then position knuckle support so that distance from rear face of support to rear face of support pin boss on rear arm is as shown in table below.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH FRONT SUSPENSION (TYPICAL)

Car Model	Arm Centered Position	Support Position
1954 (Exc. 8 Cyl. & 8 Pass.)	2 5/32"	15/16"
1954 (8 Cyl. & 8 Pass.)	2 7/32"	1 1/32"
1955 (Exc. Chrysler C69, 70, 8 Pass.)	1 11/16"	.15/16"
1955 (Chrysler C69, 70, All 8 Pass.)	1.74"	1 1/32"

FRONT SPRING: Removal—Raise front of car and place stands under frame side members behind suspension arm. Remove shock absorbers (see below) and place jack under lower control arm pivot bar where it is attached to frame crossmember. Raise jack and relieve pressure on pivot bar bolts and remove bolts (place tapered drift in each hole to keep pivot bar lined up until bolts are removed). Lower jack slowly allowing lower control arm to come down, and remove front spring.

Installation—Place spring on end in lower control arm spring seat (flat end up). Lay upper silencer on spring and install lower silencer (if so equipped).

CONTINUED ON NEXT PAGE

1954-56 CHRYSLER, DE SOTO, DODGE, PLYMOUTH (C nt.)

Install spring and upper silencer in frame crossmember, turn spring until it indexes with lower spring seat and bring lower control arm up to hold it in position. *(NOTE*–Some models have lower end coil ground flat and have flat spring seat). *Look up through spring, using a bright light, to see if upper end of spring is position correctly. Also determine (by feel) if lower end is in position.* Raise jack to align pivot bar and frame bolt holes and attach bar to frame. Tighten nuts to 60 ft. lbs.

FRONT SHOCK ABSORBER (1954): Removal - Remove nuts from upper and lower mounting studs and remove shock absorber.

Installation–Assemble new bushings in shock absorber eyes and install inner bushing retainers. Install shock absorber on studs, assemble outer bushing retainers and stud nuts. Tighten nuts to 60 ft. lbs

FRONT SHOCK ABSORBER (1955-56): Removal - Disconnect shock absorber pushrod and the lower mounting. Pull assembly, with lower bushing washer, out through lower control arm.

Installation–If it is necessary to install a new upper rod mounting bushing, wet the bushing, press it into place and install spacer. To install lower mounting assembly in shock absorber eye, position assembly so that mounting holes are at right angles with shock absorber. With Tool C-3413, and a vise, press assembly into eye until centered *(CAUTION–To avoid damaging the assembly, always press against steel sleeve).* Place lower mounting washer on rod of shock absorber and push shock into position from lower side. Install upper washer and nut, and tighten down to spacer. Install lower mounting screws and tighten to 35 ft. lbs.

1957-60 CHRYSLER, DE SOTO, DODGE, PLYMOUTH "TORSION-AIRE"

Chrysler, DeSoto, Dodge, Plymouth (1957-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*1957 PLYMOUTH FRONT SUSPENSION BALL JOINT SEAL INSTALLATION CAUTION:* Failure to install seals and seal retainer in proper position will result in dirt and moisture entering ball joint and cause loss of lubricant and noisy front suspension. Seals and retainer positions are shown in front suspension assembly.

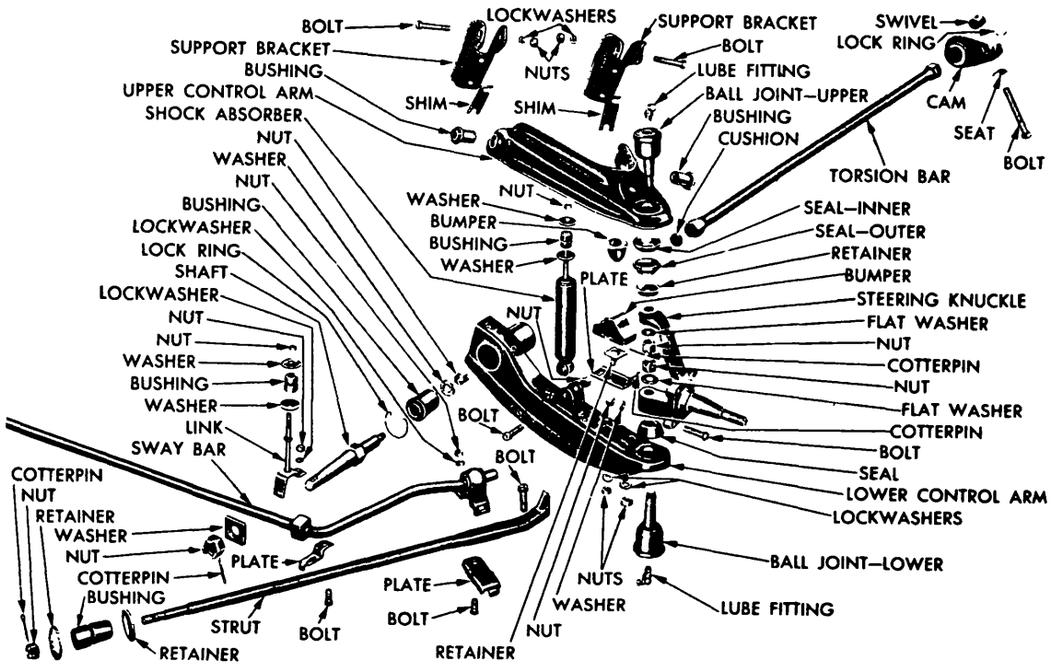
►*TORSION-AIRE SUSPENSION NOISE CORRECTION:* To properly lubricate ball joints, raise car so weight is on both lower control arms to unload lower ball joint and move upper control arm rebound bumper away from frame bracket. Use grease with not to exceed 10% lead powder and apply grease intermittently to cause ball joint action. When noise not corrected by lubrication, rotate ball joint stud ¼ turn as follows: Mark ends of both upper and lower ball joint studs and steering knuckle bosses. Start to remove knuckle or until stud-knuckle tapers are separated, then rotate studs 90° or ¼ turn from marked position. Retighten studs to specifications and thoroughly lubricate joints.

►*LOWER BALL JOINT FREEPLAY NOTE:* With suspension hanging freely, lower ball joints are loose. This is a design feature as joints are assembled without preload. No steps should be taken to eliminate this freeplay.

►*1957-58 LOWER BALL JOINT SEAL REPLACEMENT NOTE:* When replacing a lower ball joint, use new improved seal which is neoprene bonded to a steel shell.

►*1957-58 TORSION BAR REAR ANCHOR SEAL INSTALLATION:* New type seals are available for installation on these models to prevent corrosion and entry of dirt into rear anchor cavity. *See "Torsion Bar" below.*

►*1959 TORSION BAR REAR ANCHOR SEAL BOOT SERVICING: See "Torsion Bar" below.*



►*TORSION BAR SERVICE CAUTION:* When clamping torsion bar in a vise use soft blocks (copper plates or wood) on vise jaws to prevent any nicking or scarring of bar, which can result in torsion bar failure.

DESCRIPTION

DESCRIPTION: 1957-58 Models - Suspension consists of a new rubber mounted ball joint type system using torsion bars instead of front coil springs. Torsion bar springs, one on each side, are indexed with the lower control arm at inner pivot point, the other end of bar is indexed in an anchor connected to frame side rail below drivers compartment. Steering knuckles are connected to upper and lower control arms by ball joints, eliminating the kingpins. Upper control arms are attached to brackets bolted to frame side rails, and shim packs between brackets and side rails control camber and caster settings at each wheel. The lower control arm pivot point is set in replaceable rubber bushings located on back side of intermediate front crossmember. Shock absorbers are connected to lower control arm and to a frame tower. Two struts, one on each side, prevent fore and aft movement of lower control arm, and a sway eliminator bar is connected between the two struts. The forward end of the strut is attached to a frame crossmember forward of the control arms, and the other end is attached to the lower control arms.

1959-60 Models: Front suspension assembly design is similar to that used on 1957-58 Models except for new upper control arms and frame brackets. Camber and caster adjustment is made with eccentric type bolts at inner ends of upper control arms in place of the "shim" method used on 1957-58 Models. Upper control arms are attached to brackets welded to frame by special bolts having an integral cam at head of bolt. A matching removable cam is installed at threaded end of bolt. Control arm attaching brackets are provided with

CONTINUED ON NEXT PAGE

1957-58 CHRYSLER, DESOTO, DODGE, PLYMOUTH "TORSION-AIRE" ASSEMBLY

Form 53 B

1957-60 "TORSION-AIRE" (C nt.)

slotted holes and each bracket has cam retainers welded to its front and rear faces to engage cams on upper control arm attaching bolts. Rotating head of cam bolts causes upper control arm to move in slots provided in bracket. Turning one bolt will move upper control arm ball joint fore or aft to affect caster (more than camber). Turning both bolts on one side an equal amount in same direction will move upper ball joint in or out to affect camber.

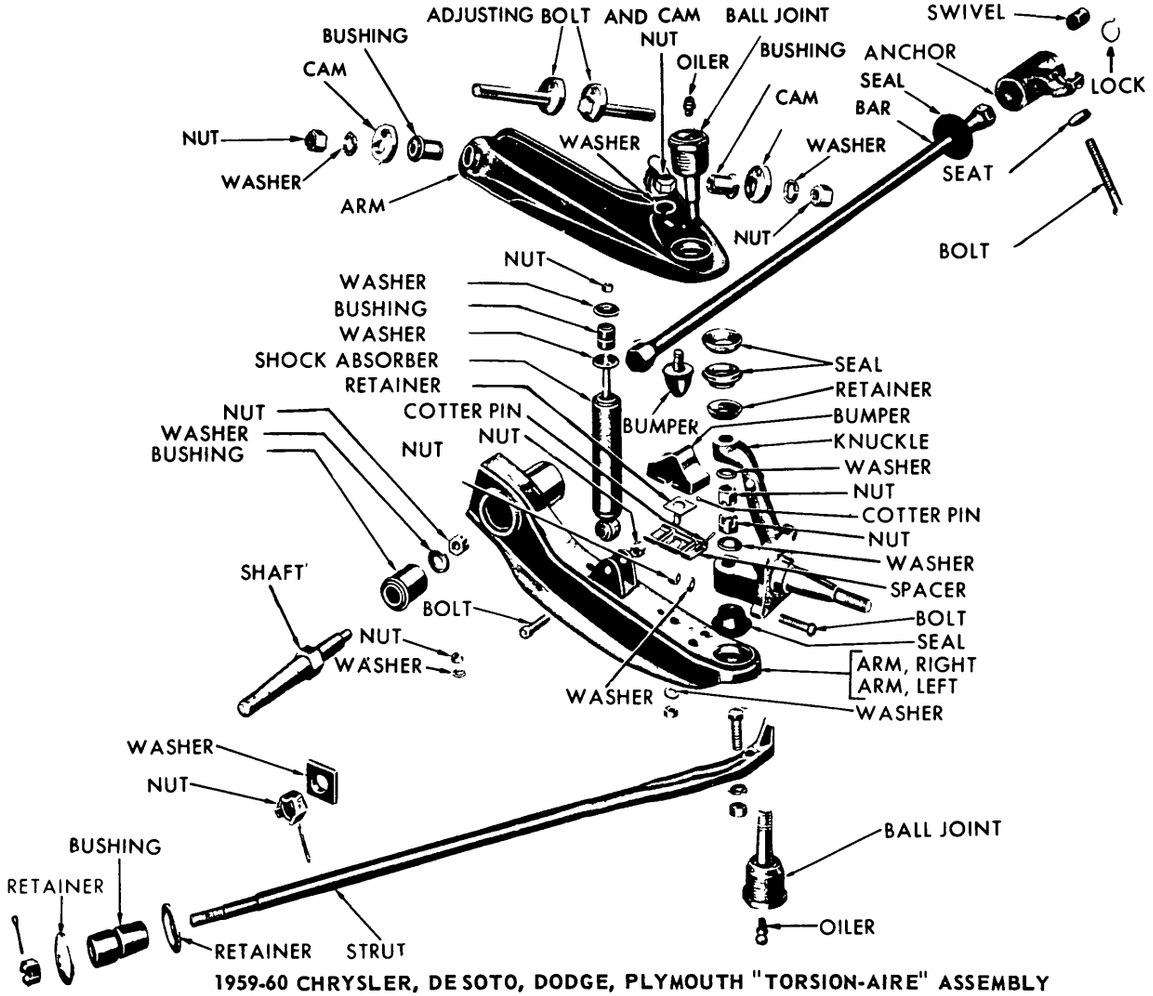
ADJUSTMENT

ADJUSTMENT NOTE: Procedures for camber and caster adjustment on 1957-58 model is different than on 1959-60 Models.

ADJUSTMENT: Before checking front wheel alignment inflate all tires to recommended pressure. Check adjustment of front wheel bearings, upper and lower ball joints, tie rod ends and idler arm for excessive loosemess. Check for bent frame and rear spring "U" bolts for tightness or shifted axle housing. Grasp front and rear bumper at center and jounce car up and down several times to place torsion bar springs and shock absorbers in their normal "unloaded" position. Make adjustments in the following order:

1957-58 MODELS

Camber: 0°±¼°, 0° preferred (right wheel); Pos. ½° to 0°, Pos. 3/8° preferred (left wheel). The addition of shims at both front and rear brackets will decrease positive camber. Shims are furnished in 1/16" and 1/32" thicknesses. One shim (1/16") at each bracket will decrease positive camber approximately 5/16°. *NOTE - Shim pack at either front or rear bracket must not exceed 9/16".* To install or remove shims, raise front wheel off floor with a jack placed under lower control arm as near to wheel as possible. Loosen upper support bracket bolts and add or remove shims.



Caster: Neg. ¾°±¾° (Manual Steering); Pos. ¾°±¾° (Power Steering). The removal of shims at rear bracket or addition of shims at front bracket will decrease positive caster. Shims are furnished in 1/16" and 1/32" thicknesses. One shim (1/16") will change caster approximately 3/8°. *NOTE - Shim pack at either front or rear bracket must not exceed 9/16".* To install or remove shims, see "Camber Adjustment" above.

Steering Axis Inclination: (Chrysler) - 5° to 7°. **(DeSoto)** - 5½° to 7°. **(Dodge & Plymouth)** - 6½°. No adjustment provided. If camber can be adjusted within recommended limits it is unnecessary to check steering axis inclination. *CAUTION - Do not heat parts in order to straighten.*

Toe-In: 1/8"±1/32". 1/8" preferred. Lengthen or shorten tie-rods an equal amount until wheels toe-in specified amount.

NOTE - Steering wheel hub, steering gear arm, steering tube and steering gear roller shaft are machined with master serrations to place front wheels in straight ahead position when steering wheel is centered. Do not alter these serrations to change position of these parts. Improper position of steering wheel must be corrected by adjusting tie rod lengths.

Toe-Out on Turns: With outer wheel at 20°, inner wheel should be 21½°±1° (Chrysler, DeSoto, Dodge). With inner wheel at 20° outer wheel should be 17½-19° (Plymouth). *CAUTION* - Replace parts that are bent, DO NOT straighten by heating.

1959-60 CHRYSLER, DE SOTO, DODGE, PLYMOUTH "TORSION-AIRE" ASSEMBLY

1959-60 MODELS

Steering Axis Inclination: 6½° at 0° camber (1959); 5½ to 7½° (1960). No adjustment.

Caster: 1959 Models - Neg. ¾°±¾° (Manual Steering); Pos. ¾°±¾° (Power Steering).

1960 Models - Neg. ½°±½° (Manual Steering); Pos. ¾°±½° (Power Steering).

Adjustment - Adjust caster by turning one eccentric bolt at a time as necessary to obtain the correct setting. *NOTE - Turning both eccentric bolts in opposite directions affects caster with a minimum amount of change in camber.*

Camber: 1959 Models - 0°±¼°, 0° preferred (right wheel); Pos. ½° to 0°, Pos. 3/8° preferred (left wheel).

1960 Models - Pos. 3/8°±¼°, Pos. 3/8° preferred (right wheel); Pos. 1/8°±¼°, Pos. 1/8° preferred (left wheel).

Adjustment - Adjust camber by turning both eccentric bolts equally in same direction as necessary to obtain correct setting. *NOTE - Turning both eccentric bolts in the same direction affects camber with a minimum amount of change in caster.*

Toe-In: 3/32-5/32" (1/8" preferred).

Toe-Out on Turns: 1959 Models - With inner wheel at 20°, outer wheel should be 18°46' (Chrysler Windsor, DeSoto Firesweep, Dodge & Plymouth); 18°26'(Chrysler, except Windsor); 18°30' (DeSoto, Except Firesweep). No adjustment.

1960 Models - With outer wheel at 20°, inner wheel should be 21½±1°.

Front Suspension Height: Checking - Make sure the car is on a level floor, tires inflated to recommended pressure, and car at curb weight (full gas tank, no passengers or load). Measure from lowest point of lower support arm ball joint to floor and from underside of lower

CONTINUED ON NEXT PAGE

1957-60 "TORSION-AIRE" (C nt.)

control arm bushing (at center line of bushing housing) *(NOTE - Under car weight, the bushing housing will always be higher than the ball joint housing)* The difference between these two measurements should be as specified in table below If the difference in measurements between the two sides of the car are less than ¼" (1957-59), 1/8" (1960) of each other and are within the limits specified, suspension height is correct If these measurements differ more than ¼" (1957-59), 1/8" (1960), or if one or both of them are outside specified limits, then torsion bars must be adjusted

1957 Front Susp nsion Height Limits

M del	① Height Difference
Chrysler (All Models)	2 1/8-2 1/4"
DeSoto (Exc Sta Wgn)	2 1/8-2 1/4"
DeSoto (Sta Wgn)	2 5/8-2 3/4"
Dodge (Sed & Coupe)	1 7/8-2 3/8"

"TORSION-AIRE" SUSPENSION SYSTEM

Adjustment - Tighten or loosen the adjusting bolt at rear end of each torsion bar until measurement differences are as specified *NOTE - Always jounce front and rear after making adjustment prior to a height check Also when torsion bar spring adjustment is made, check alignment of front wheels and headlight aiming*

REMOVAL & INSTALLATION

SWAY BAR: (Removal) - Remove sway bar link retaining nuts and washers and the two sway bar cushion retaining bolts (one on each strut) Slide sway bar out through control arm struts and away from car *NOTE* - Sway bar cushions are not serviced separately

Installation: Dip new sway bar link bushing in water, install in opening in frame bracket, using a twisting motion When installed properly, the groove in bushing will index with opening in frame bracket Thread sway bar into position over top of lower control arm struts Engage sway bar cushion housing with struts and install lock plates Insert bolts and lockwashers and tighten to 25 ft lbs Install washers over ends of links (concave side up), then slide links up through bushings Install washers (concave side down), over ends of links and down on bushings Install nuts and tighten to 15 ft lbs

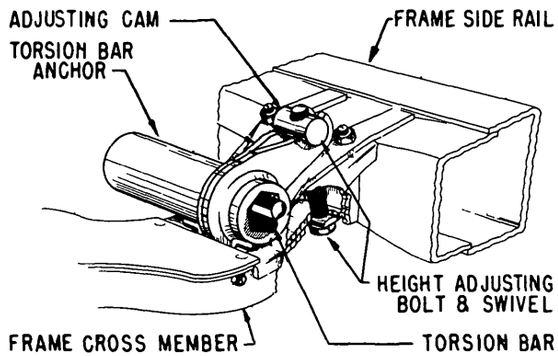
LOWER CONTROL ARM STRUTS: (Removal) - Remove bolts attaching sway bar bushing housing to struts Disconnect sway bar from struts Remove the strut-to-lower control arm mounting bolts and nuts Remove cotter pin nut and bushing retainer from forward end of strut at front crossmember Slide strut and inner bushing retainer from bushing in frame Cut old bushing out of frame with a knife

Installation: Dip new bushing in water and with tapered portion toward rear of car, install in opening in frame using a twisting motion until groove in bushing indexes with frame With cupped side out slide washer over threaded end of strut Push strut through bushing in frame Slide outer washer over end of strut (cupped side in) Install nut and tighten sufficiently to install strut to lower control arm mounting bolts Install bolts, lockwashers, and nuts and tighten to 65 ft lbs Tighten strut nut to 30 ft lbs and install cotter pin Check caster and camber

STEERING KNUCKLE: (Removal) - Remove wheel, tire and drum Cover brakes with a clean cloth and remove cotter pins, nuts and lockwashers attaching steering arm and brake dust shield to steering knuckle Remove steering arm and brake assembly from steering knuckle (leave brake hose attached) (Do not allow assembly to hang by the brake hose) Remove ball joint studs from steering knuckle (see "Upper & Lower Ball Joints" below) Lift steering knuckle up and away from car

Installation: Slide upper and lower ball joints into steering knuckle and install lockwashers and nuts Tighten ball joint stud to 135 ft lbs Install cotter pins Slide brake assembly over knuckle and into position Install lockwashers and nuts on upper rear and lower front bolts Install upper front and lower rear bolts through dust shield and steering knuckle, then slide steering arm over bolts Install lockwashers and nuts and tighten evenly to 55 ft lbs Install cotter pins Remove covering from brake shoes, replace wheel and drum assembly Adjust front wheel bearings.

UPPER & LOWER BALL JOINTS: (Removal) - *(CAUTION - Upper and lower ball joints are not interchangeable The Upper joint is preloaded and should not be used in the lower control arm)* Remove wheel assembly, and remove upper and lower ball joint stud nuts (Install Tool C-3564 (with threaded end upward to remove lower joint, and with threaded end downward to remove upper joint) Apply load to studs and rap knuckle at ball joint boss sharply with a hammer to loosen stud *(CAUTION Do not attempt to hammer stud out of knuckle)* Reverse position of tool to remove the opposite ball joint and



CONTINUED ON NEXT PAGE

1957-60 "TORSION-AIRE" (C nt.)

repeat the above procedure Remove tool and disengage ball joint from knuckle Remove dust cover and grease seal Remove lubrication fittings Use a suitable tool (C-3560, C-3561 or equivalent) and unscrew ball joint from control arm

Installation: *CAUTION - When installing new ball joints, make sure that ball joint threads squarely engage threads in control arm* With lubrication fittings removed, screw ball joint into control arm using a suitable tool (C-3560, C-3561 or equivalent) and tighten until ball joint housing is seated in control arm Tighten to a minimum of 250 ft lbs Install seal and dust cover in position over stud and place stud in steering knuckle Install cotter pin and lubrication fitting, then lubricate ball joint with chassis lubricant

TORSION BAR: (Removal) - *(CAUTION - Torsion bars are not interchangeable, side for side Torsion bars are*

TORSION BAR ANCHOR & ADJUSTMENT

marked "L" (Left), "R" (Right), stamped on one end of the rod These stamped markings must always be toward rear of car) Raise car off floor *by jacking under front crossmember* Release load from torsion bar by unscrewing the cam adjusting bolt partly out of swivel *(CAUTION - To prevent swivel from falling into frame bracket, do not loosen swivel bolt all the way out until torsion bar is removed)* Remove seal assembly (if so equipped) from rear end of torsion bar anchor, then remove lock ring from anchor Slide torsion bar rearward sufficiently to disengage from lower control arm, then slide bar forward and down to disengage it from anchor Remove anchor adjusting bolt, swivel and seal

Installation: 1957-58 Models - Replace anchor bolt and swivel with new parts, then tap rear anchor to loosen all dirt and thoroughly clean socket in rear anchors *NOTE - If there is moisture in cavity, rinse with methanol type anti-freeze and blow dry with air* Check torsion bar cushion in lower control arm housing and make sure it is in place at end of lower control arm pivot shaft With cam bolt barely entered in cam swivel, slide torsion bar into rear cam, then rotate cam and torsion bar until cam is positioned as close to floor pan as possible Engage front of torsion bar in lower control arm shaft assembly as far as bar will go (up against cushion) *NOTE - Unless anchor is positioned properly, it will be impossible to adjust front suspension to proper specifications* Install lock ring in rear of cam housing and tighten cam bolt until approximately 1" of threads show above anchor bolt swivel Force approximately 1/3 lb of short fibre wheel bearing grease into cavity between anchor and torsion bar *NOTE - This can be done by holding a cloth firmly against mouth of anchor and applying grease with a high pressure gun until entire cavity is full and grease is forced out of cavity* Install Torsion Bar Seal Package, Part No 2196067 (small size torsion bar), Part No 2196068 (large size torsion bar), as follows Place new type seal on torsion bar with tapered end toward rear anchor (split side must be on bottom of anchor), then push tapered end of seal into annular grease filled space in anchor Use a ¼" wide, blunt ended non-metallic tool and gently force seal into opening by pushing on the outer diameter, compressing seal and packing it into the opening *NOTE - This should be done in many steps around outside of seal until it is uniformly packed into the anchor and is flush with forward face of anchor* Wrap plastic clamp around the bar with "Teeth" toward the outside, then thread flat end through the loop and slide plastic seal clamp tight against rubber seal Pull flat end until clamp is tight around bar Check and adjust suspension height, caster, and camber

1959 Models - Installation procedures are the same as for 1957-58 models except that it is not necessary to install Torsion Bar Seal Package If original seal boot is damaged, replace with a new boot, Part No 1613388, as follows Coat each end of torsion bar with wheel bearing grease, then install boot on bar, small diameter toward front of car Install torsion bar and slide boot over end of anchor Adjust suspension height, caster, and camber

1960 Models - *NOTE - A new adjusting bolt and swivel must be installed* Slide new rear anchor end seal over torsion bar with cup side toward rear Apply a liberal coating of wheel bearing grease around each end of torsion bar *NOTE - Rear end of bar should be coated equal to depth of anchor hub socket* Install torsion bar and position end seal in groove on anchor hub Turn torsion bar until anchor end is positioned 120° (eight o'clock position) down from frame *CAUTION - If anchor end is not in proper position when installing torsion bar it will be impossible to adjust front suspension height correctly* Install plastic seal into rear end of anchor Slide new adjusting bolt swivel into position on frame and hold in position while installing new adjusting bolt and seal, then tighten bolt until 1" of threads are showing out of swivel Lower car to floor and adjust suspension height, caster, and camber

►**1957-60 TORSION BAR SEAL REPLACEMENT (WITHOUT REMOVING TORSION BAR).** On 1957-58 Models, remove rear anchor to torsion bar seal (if installed), then forcibly tap anchor to loosen all dirt and scale accumulated between inside diameter of anchor and torsion bar Blow out space between bar and anchor *NOTE - If moisture is present in the cavity, rinse with methanol-type anti-freeze and blow dry with air* Force approximately 1/3 lb of short fibre wheel bearing grease into cavity between anchor and torsion bar by holding a cloth firmly against mouth of anchor and applying grease with a high pressure gun until cavity is full Install Torsion Bar Seal Package, Part No 2196067 (small size torsion bar), Part No 2197068 (large size torsion bar), as follows Place new type seal on torsion bar with tapered end toward rear anchor (split side must be on bottom of anchor), then push tapered end of seal into annular grease filled space in anchor Use a ¼" wide, blunt ended non-metallic tool and gently force seal into opening by pushing on outer diameter, compressing seal and packing it into the opening *NOTE - This should be done in many steps around outside of seal until it is uniformly packed into the anchor and is flush with face of anchor* Wrap plastic clamp around bar with "Teeth" toward outside then thread flat end through the loop and slide plastic seal clamp tight against rubber seal Pull flat end until clamp is tight around bar On 1959-60 Models, the 1957-58 seal packages may be used to replace balloon type seal if only the seal is to be replaced and torsion bar is not to be removed from car

UPPER CONTROL ARM: (Removal) - *Place jack under lower control arm and raise front wheel off floor,* with jack placed as close to wheel as possible Remove wheel Remove cotter pin, nut and washer from upper ball joint stud Install tool C-3564 and remove ball joint (See "Upper & Lower Ball Joints" above) Remove upper control arm front and rear pivot bolts Remove control arm from support mountings (do not remove brackets from frame)

Upper Control Arm Bushing Replacement: Remove bushings by pressing them out with Tool C-3558 (1957-58) C-3710 (1959-60) *NOTE - A hammer and suitable drift may be used to remove bushings if support arm is properly supported and care is taken not to damage bushing surface in control arm* When installing new bushings, make sure control arm is supported at point bushing is pressed in Position flange end of bushing in Tool C-3558 (1957-58), C-3710 (1959-60) then use an arbor press and install bushing until flange is seated against arm

Installation: Position upper control arm in frame mounting bracket and install mounting bolts, washers and nuts With control arm in normal position, tighten nuts to 65 ft lbs (1957-58 Models), 55-65 ft lbs (1959-60 Models) Place upper ball joint in steering knuckle and install washer and nut Tighten to 135 ft lbs (1957-58), 100 ft lbs (1959-60 Chrysler Windsor, DeSoto Fireflite, Dodge & Plymouth), 135 ft lbs (Other 1959-60 Models), then secure with a cotter pin

LOWER CONTROL ARM: (Removal) - Raise car by placing jack under frame crossmember Remove torsion bar (see "Torsion Bar" above) Remove shock absorber lower eye attachment nut and bolt from mounting bracket Push lower portion of shock absorber up into frame opening Remove strut to lower control arm mounting bolts Remove lower ball stud from knuckle (see "Upper & Lower Ball Joints" above) Remove cotter pin nut and washer from lower control arm shaft assembly With washer removed, reinstall nut (to protect threads) until it is flush with end of shaft, (shaft is a tapered fit in crossmember) Use a hammer and brass drift for loosening then remove nut from shaft Slide lower control arm and shaft assembly from rear crossmember *(CAUTION - Do not lose torsion bar spring cushion located in shaft assembly)*

CONTINUED ON NEXT PAGE

1957-60 "TORSION-AIRE" (C nt.)

Installati n: Position shaft and lower arm assembly in crossmember in normal position, and install washer and nut. Tighten to 175-200 ft lbs and secure with a cotter pin. Position lower ball joint stud in steering knuckle and install washer and nut. Tighten nut to 135 ft. lbs. and secure with a cotter pin. Place shock absorber in position in lower mounting bracket and install bolt and nut and tighten to 40 ft. lbs. Install wheel. **Do not lower front of car until torsion bar spring is installed.** See "Torsion Bar" above.

LOWER CONTROL ARM PIVOT SHAFT BUSHING RE. PLACEMENT: (Disassembly) - Remove lock ring from end of bushing housing. Support lower control arm assembly in an arbor press, then using a brass drift, press shaft and bushing assembly from control arm. Remove cotter pin, nut and washer; and slide bushing from shaft.

Reassembly: Position new bushing (flanged end of bushing first) on shaft and install washer and nut. Tighten nut to 100-150 ft. lbs. and install cotter pin. With lower control arm supported, install shaft and bushing assembly by using Tool C-3556 or C-3557 and pressing bush- into lower control arm until flange portion of bushing is seated all the way into control arm. Install lock ring making sure it is properly seated in ring groove. Install torsion bar spring cushion in control arm.

UPPER CONTROL ARM SUPPORT MOUNTING BRACK-ETS: *CAUTION - 1959-60 brackets are welded to frame and cannot be removed. On 1957-58 Models, brackets are bolted to frame and should not be removed unless damaged due to accident.* On 1957-58 Models, when removing mounting brackets, care should be taken not to lose alignment shim pack located between bracket and frame side rail. In the event a shim pack is lost, a selection of shims 5/16" thick, **may be used as a starting point when reassembling.**

VALIANT "TORSION-AIRE" FRONT SUSPENSION

Valiant (1960)

DESCRIPTION: Independent type with torsion bars instead of conventional type coil springs. Upper control arms are attached to brackets which are welded to shock absorber tower and to body horizontals (side rails). Lower control arms are attached to the "K" type front suspension crossmember which is connected to body horizontals (side rails). Ball joints are used to attach both upper and lower control arms to steering knuckles. Torsion bars are anchored at rear to engine rear support member in the body and at the front to lower control arm. Eccentric bolt assemblies at upper control arms control camber and caster adjustments. Car riding height is controlled by a lever assembly at front end of each torsion bar.

TIRE INFLATION: Tir s Cold - 24 lbs. (Front, All Models); 24 lbs. (Rear, Sedan & 2-Seat Sta. Wgn.); 28 lbs. (Rear, 2 & 3-Seat Sta. Wgns. With Captive Air Tires). *NOTE - Captive Air Tires are standard on 3-S at and optional on 2-Seat Station Wagons.*

ADJUSTMENT: With car at curb weight (fuel tank full but with no luggage or passenger load), tires at recommemded pressure (see above) and with front suspension and steering linkage in good condition, make adjustments in the following order:

►*NOTE: Jounc car up and down several times at center of bumpers (r ar bump r first) prior to taking each m asur m nt. Car should be jounced the same number of tim s and th bump r should be released at the same point in cycl ach tim .*

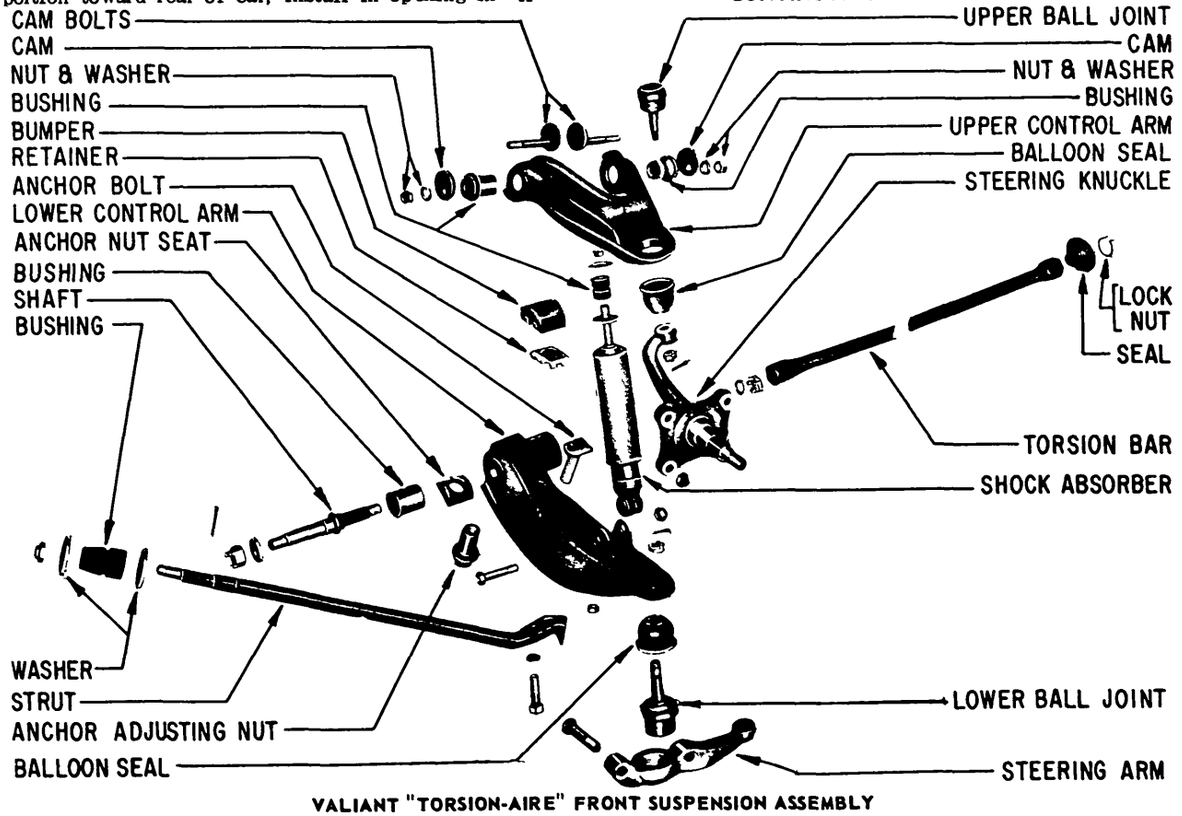
Front Riding H ight: Jounce car and measure from lower ball joint to floor and from control arm torsion bar spring anchor housing to floor. Subtract first measurement from second measurement. The difference should be 1¾" ± 1/8". The difference from one side of car to the other should not exceed 1/8". To adjust, turn nut on lower side (inner end) of lower control arm clockwise to increase height and counterclockwise to decrease height. After adjusting, jounce car and recheck height.

Cast r: Neg. ½° ± ½° (Manual Steering). Pos. ¾° ± ½° (Power Steering). Adjust caster by turning **one** eccentric bolt at a time as necessary to obtain correct setting. *NOTE - Turning both eccentric bolts in opposite directions aff cts caster with a minimum amount of chang in camber.*

Camb r: Right Wheel - Pos. 1/8° ± ¼° (Pos. 1/8° preferred); Left Wheel - Pos. 3/8° ± ¼° (3/8° preferred). Adjust camber by turning both eccentric bolts equally in the same direction as necessary to obtain correct setting. *NOTE - Turning both ecc ntric bolts in th sam dir ction aff cts camb r with a minimum amount f chang in caster.*

T e-In: 1/8" ± 1/32". Turn both tie rod adjusting tubes equally with steering wheel centered and steering gear on "high point" for straight ahead travel. *NOTE* - Before tightening clamps, turn tie rod assembly so sockets are either against front or back sides of studs. Tighten bolts to 15 ft. lbs.

Steering Axis Inclination: 6½° to 8½°. Not adjustable.



Toe-Out on Turns: With inner wheel at 20°, outer wheel should be at 17° 40' ± 1°.

LOWER CONTROL ARM STRUT: Removal - Remove strut to lower control arm mounting bolts and nuts, then remove nut and bushing retainer from forward end of strut at crossmember. Slide strut and inner bushing retainer from bushing, then pry bushing out of "K" member.

Installation: Dip new bushing in water and, with tapered portion toward rear of car, install in opening in "K" member, using a twisting motion until groove in bushing seats properly with support member. With cupped side out, slide bushing retainer over threaded end of strut. Push strut through bushing in crossmember, position outer bushing retainer over end of strut (cupped side in) and install nut finger tight. Install strut-to-lower control arm mounting bolts, lockwashers and nuts and tighten to 100 ft. lbs. Lower car to floor, then with full body weight on wheels, jounce car to permit bushing to assume its normal position on strut. Tighten nut on forward end of strut to 40 ft. lbs.

TORSION BARS: *NOTE - Torsion bars are not int r-changeable side for side. Bars are marked with eith r*

CONTINUED ON NEXT PAGE

VALIANT "TORSION-AIRE" FRONT SUSPENSION ASSEMBLY

VALIANT "TORSION-AIRE" FRONT SUSPENSION (C ntinu d)

"L" or an "R" stamped n ne nd of bar r by a number consisting of the last three digits of the part number. An even numbered bar is for right hand side. An odd numbered bar is for left hand side.

R m val: Raise car so front suspension is in full rebound position (under no load). *NOTE - If a hoist is used, make sure car is lifted on body. If a jack is used, place jack under center of "K" member.* Release load from torsion bar by backing off anchor adjusting nuts located on lower side (at inner end) of lower control arm, then remove adjusting nut and swivel bolt. Remove strut (see above), then remove lock spring from rear of torsion bar rear anchor. Install Tool C-3728 on torsion bar and remove bar rearward by holding tool firmly and hitting striking pad with a hammer. *CAUTION - Do not apply heat to front or rear anchors and do not mar or scratch torsion bar during removal or installation.* Remove tool and slide rear anchor balloon seal off front end of bar, then remove bar by sliding it rearward and out through rear anchor.

Installation: Remove all foreign matter from hex openings in front and rear anchors and from hex ends of torsion bars. Insert torsion bar through rear anchor, then slide rear anchor balloon type seal over torsion bar with large cupped side of seal facing to rear. Coat both ends of torsion bar with multi-purpose grease. When inserting torsion bar into lower control arm, position adjusting arm approximately 60° below plane of control arm (otherwise adjustment of front suspension to correct height will not be possible). Install lock ring in rear anchor, then move torsion bar rearward until bar contacts lock ring. Position swivel bolt on control arm and hold in place while installing adjusting nut and seat. Tighten adjusting nut approximately 10 turns before lowering car to floor. Pack annular opening in rear anchor with multi-purpose grease, then slide rear anchor balloon type seal into position over rear anchor until lip of seal indexes with groove. Install strut (see above), then lower car to floor and adjust front suspension height (see above).

UPPER BALL JOINTS: Removal - Place jack under lower control arm as close to wheel as possible, then raise wheel off floor and remove wheel. Remove upper ball joint stud nut, then place Tool C-3711 down on flat section of lower control arm and turn threaded portion of tool, locking it securely against upper stud. Spread tool enough to place upper stud under pressure. Strike steering knuckle sharply with a hammer to loosen stud. *CAUTION - Do not try to force stud out of knuckle with tool alone.* Remove tool, then disengage ball joint from knuckle. Remove ball joint balloon type seal by prying metal retainer edge loose with a screwdriver. Use Tool C-3714 and unscrew ball joint from upper arm.

Installation: *CAUTION - When installing a new ball joint, it is very important that ball joint threads contact and engage those of the control arm squarely. Always replace balloon type seals with new ones once th y have been removed.* Screw ball joint squarely into control arm as far as possible by hand, then use Tool C-3714 and tighten until ball joint housing is seated on control arm. Tighten to a minimum of 125 ft. lbs. Slide a new balloon type seal up into position over stud, and install seal with Tool C-3713. Position stud in steering knuckle, install washer and tighten nut to 55 ft. lbs. then install cotter pin. Lubricate ball joint with chassis lubricant and install wheel.

LOWER BALL JOINTS: R moval - Place jack under lower control arm and raise car, then remove wheel and brake drum as an assembly. Disconnect tie rod from steering arm, then remove nut and loosen stud by striking arm sharply while "backing up" with a heavier hammer. Remove bolts attaching steering knuckle arm assembly to brake backing plate and support brake backing plate to eliminate strain on brake hose. Use Tool C-3646 to disconnect lower ball joint from lower control arm, then remove steering arm assembly. Place the assembly in a vise and remove balloon seal, then use Tool C-3714 and remove ball joint from steering arm.

Installation: *CAUTION - When installing a new ball joint, it is very important that ball joint threads engage those of steering arm squarely. Always replace balloon type seals with new ones once they have been removed.* Screw ball joint into steering arm as far as it will go by hand, then use Tool C-3714 and tighten ball joint housing to a minimum of 300 ft. lbs. until ball joint is seated in steering arm. Slide a new ball joint balloon seal onto ball joint being careful not to pinch rubber or deform metal retainer of seal. Lubricate ball joint with chassis lubricant, then install steering knuckle arm assembly on brake support plate and connect ball joint to lower control arm and the tie rod end to steering knuckle arm. Tighten ball joint stud nut to 90 ft. lbs. and tie rod end nut to 50 ft. lbs.

LOWER CONTROL ARM & SHAFT: Removal - Place a jack under "K" member and raise car until both front wheels are off the floor. Disconnect strut from lower control arm, then remove torsion bar (see above). Remove wheel and drum as an assembly, disconnect shock absorber at lower control arm bracket, then push shock absorber up out of way. Disconnect lower ball joint stud from lower control arm with Tool C-3646. Support brake backing plate to remove strain from brake hose. Remove cotter pin, nut and washer attaching lower control arm shaft to "K" member, then with cotter pin and washer removed, reinstall nut until flush with end of shaft to protect threads. Use a hammer and brass drift and loosen shaft (shaft is a tapered fit in "K" member), then remove nut. Slide lower control arm and shaft out from rear of crossmember.

Disassembly: Place lower control arm in an arbor press with torsion bar hex opening up. Use a brass drift through opening and press shaft and nut out of lower control arm bushing. Cut and remove rubber portion of bushing from control arm, then cut and collapse bushing shell and remove it from control arm. Remove cotter pin, nut, washer, and remainder of bushing from shaft.

Reassembly: Position new bushing over shaft (flange end first) and seat on shoulder of shaft. Install nut and washer and tighten to 90 ft. lbs. *NOTE - Hold shaft securely in a vise, using protector jaws, when tightening nut.* Install cotter pin. Press lower control arm shaft and bushing into lower control arm assembly with an arbor press and, using Tool C-3712, press in until flanged portion of bushing is seated past lock groove.

Installation: Clean mounting surface thoroughly, then position shaft and control arm in "K" member in approximate operating position. Install washer and nut finger tight. Connect upper ball joint to steering knuckle and tighten to 55 ft. lbs. Connect shock absorber to its bracket on lower control arm and tighten nut to 55 ft. lbs. Install torsion bar, strut, and wheel assembly. Lower car to floor and with full body weight on wheels, jounce car, adjust front suspension height, then tighten lower control arm shaft nut to 160 ft. lbs. and install cotter pin.

UPPER CONTROL ARMS: R m val - Place a jack under lower control arm as close to wheels as possible, then raise car until wheels clear floor. Remove wheel, then remove upper ball joint stud from steering knuckle with Tool C-3711. Remove nuts, lockwashers, cams and cam bolts that attach upper control arm and bushings to front and rear supports. Lift upper control arm up and away from supports.

Disassembly: Remove balloon seal by prying retainer loose with a screwdriver, then remove ball joint with Tool C-3714. Assemble Tool C-3710 over bushing and press out of arm. *NOTE - Press from insid arm.*

Reassembly: *NOTE - When installing new bushings, support control arm squarely at point wh r bushing is being pressed in. Do not use oil or gr ase to aid in installation.* Position flange end of new bushing in Tool C-3710, then support control arm squarely and force bushings into control arm (from outside of arm) until tapered portion of bushing seats on arm. Install ball joint into arm with Tool C-3714 and tighten until it is seated (125 ft. lbs. minimum). *NOTE - Ball joint will cut threads in a new control arm during tightening operation. Install a new seal with Tool C-3713.*

Installation: Slide upper control arm into position and install control arm cam bolts, removable cams and nuts and tighten nuts in preparation for final adjustments. Slide upper ball joint stud into position in steering knuckle and install washer and nut. Tighten nut to 55 ft. lbs. and install cotter pin. Install a new ball joint seal with Tool C-3713. Check and adjust car height and front suspension alignment, then tighten control arm cam bolt nuts to 65 ft. lbs.

STEERING KNUCKLES: Rem val - Place jack under lower control arms as near to wheel as possible and remove wheel and brake drum as an assembly. Disconnect upper ball joint stud from steering knuckle with Tool C-3711. Remove nuts and bolts attaching brake support plate assembly to steering knuckle and steering knuckle arm assembly, then remove steering knuckle. *CAUTION - Do not allow brake support assembly to hang by brake hose.*

Installation: Position steering knuckle and steering knuckle arm assembly on brake support assembly and install mounting bolts and nuts. Tighten upper nuts to 55 ft. lbs. and lower nuts to 50 ft. lbs. Position upper control arm ball joint stud in steering knuckle and install stud nut and tighten to 55 ft. lbs., then install cotter pin.

FRONT SUSPENSION CROSSMEMBER ("K" MEMBER): Removal - Disconnect engine front supports from "K" member, then remove carburetor air cleaner and throttle rod. Attach engine lifting plate, Tool C-3804 to cylinder head, then attach lifting fixture, Tool C-3809 to lifting plate and lift engine off "K" member. Raise car and support it under flat sections of side members forward of the crossmember under transmission, leaving front suspension in full rebound position. Remove both struts, then back off torsion bar anchor adjusting nuts. Remove idler arm from "K" member, then remove lower control arm pivot shafts from "K" member. Remove "K" member bolts and move forward and down, tapping lower control arm pivot shafts with a plastic hammer.

Installation: Lift "K" member into position, guiding both lower control arm shafts into "K" member. Install attaching bolts but do not tighten. Install lower control arm shafts and tighten nuts to 160 ft. lbs. Install idler arm and tighten to 85 ft. lbs. Install struts and tighten to 40 ft. lbs. at crossmember and to 100 ft. lbs. at lower control arms. Tighten torsion bar anchor adjusting nuts, temporarily, approximately 8-10 turns. Tighten "K" member attaching bolts to 150 ft. lbs., then remove body supports. Lower engine and install front support bolts and remove lifting tools.

COMET & FALCON FRONT SUSPENSION

Comet (1960)
Falcon (1960)

►CHANGES, CAUTIONS, CORRECTIONS

►*FRONT SUSPENSION LOWER CONTROL ARM STRUT SERVICE REPLACEMENT NOTE & ADJUSTMENT CAUTION:* A new kit, Part No. CODZ-3468-A which includes a new longer spacer, insulators, strut, and attaching parts is available for service replacement. Strut adjustment specifications are different when the new kit is installed. *See "Lower Control Arm Strut Adjustment" below.*

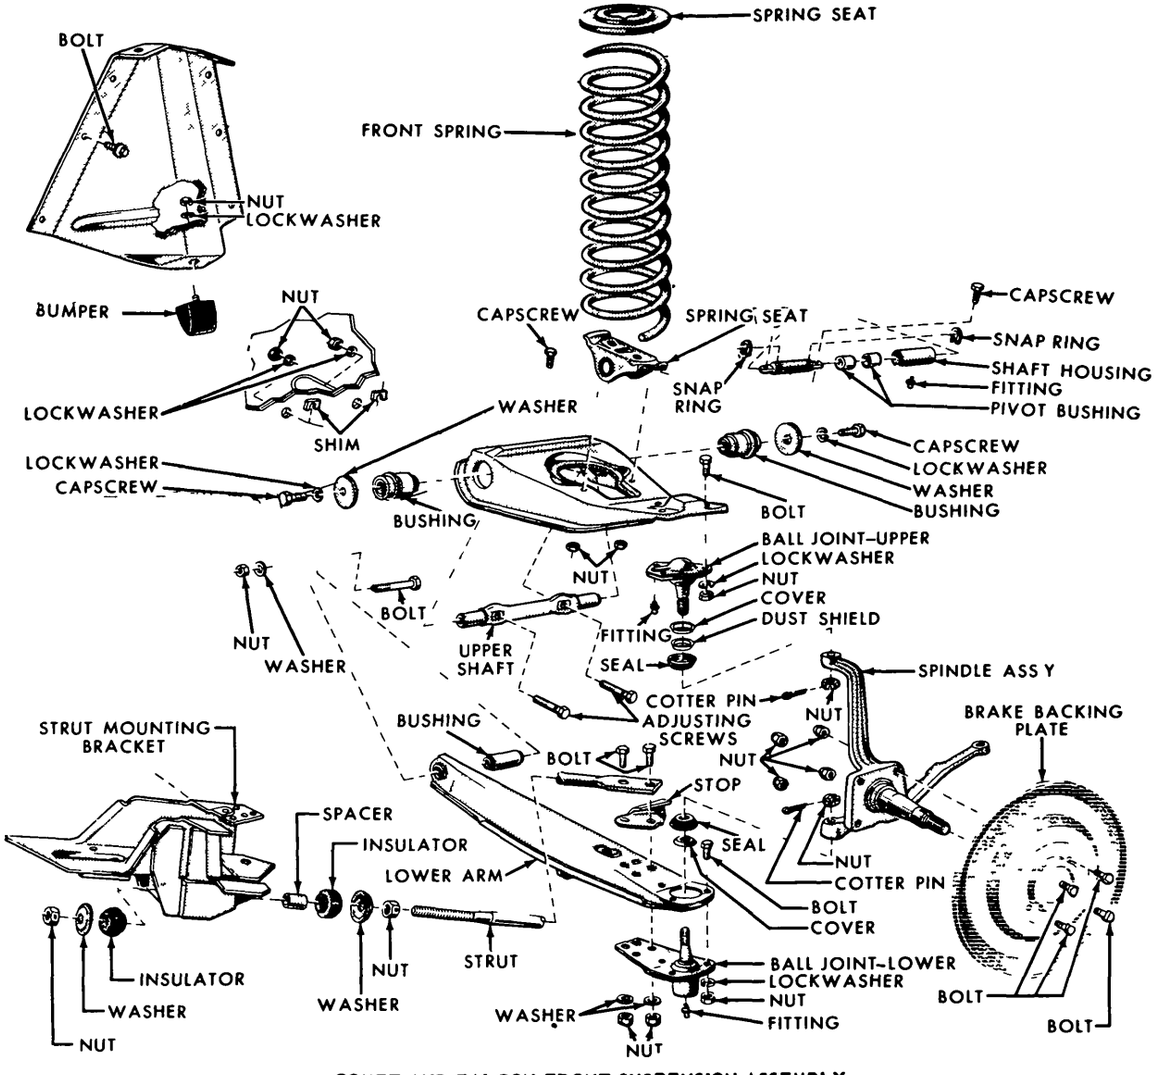
DESCRIPTION: "Ball-Joint" type suspension with front coil spring and shock absorber mounted between upper control arm and tower in wheel housing. Lower control arm is connected to underbody with a mounting bolt. A strut connected between outer end of lower strut and bracket at forward end of underbody prevents horizontal movement of lower control arm. Shims located between upper control arm inner shaft and mounting bracket control camber and caster adjustments.

CHECKING & ADJUSTING: Before adjusting front end alignment, inflate tires to specified pressure (see below). Raise front of car and check front suspension ball joints for looseness, wear, or damage. *CAUTION – Do not raise car with jack under lower suspension arms.* Check steering gear mountings and all linkage for looseness. Adjust front wheel bearings. Check tracking of front and rear wheels.

►*ADJUSTMENT NOTE: Previous adjustment specifications are superseded by the following:*

Tire Inflation: Falcon - (Sedan) 24 lbs. front & rear. (Station Wagon) 22 lbs. front, 30 lbs. rear. (Ranchero) 24 lbs. front, 30 lbs. rear.
Comet - 22 lbs. front, 26 lbs. rear.

Caster: 0° to Pos. 1°. Preferred setting is ½° (Comet), 0° (Falcon). *NOTE - Maximum variation from side to side should not exceed ½° (¼° preferred).*



Camber: 0° to Pos. 1° (½° preferred). *NOTE - Maximum variation from side to side should not exceed ½° (¼° preferred).*

Toe-In: ¼" to 5/16" (9/32" preferred).

Toe-Out on Turns: With outer wheel turned 20°, inner wheel should be 20¾°.

Shimming Procedure: Camber and caster adjustments are made by adding or removing shims between upper control arm inner shaft and mounting pad. To change caster, remove or add shims at one of the mounting bolts. The removal of shims at front bolt or installation of shims at rear bolt will cause ball joint on upper control arm to move forward. Reversing this procedure will cause joint to move to rear. A 1/32" change of shim thickness at either bolt will change caster angle ½°. *NOTE – The difference between shim thicknesses at the two bolts should not exceed 1/16" and the maximum thickness of shim stack at each bolt must not exceed 9/16".* To adjust camber, remove or install equal shim thicknesses at both bolts. Removal of shims at both bolts will move upper ball joint inward, and installation of shims will move upper ball joint outward. A 1/16" change in shim thickness at both bolts will change camber angle 1/3°.

Lower Control Arm Strut Adjustment: Adjust length of strut by turning front and rear nuts securing strut to frame body member to a length of 17¾" (cars with early type 1.42" long insulator spacer); 17 5/8" (cars with later type 1.58" long insulator spacer), measured from back face of rear insulator washer to center strut-to-lower control arm front attaching bolt. The correct distance between insulator washers when the strut rod nut is tightened to 40-50 ft. lbs. is 1.15" (short spacer); 1.30" (long spacer). *NOTE - If the distance between insulator washers with nuts tightened to 40-50 ft. lbs. is .88", the spacer has been omitted and must be installed before operating car.*

COMET AND FALCON FRONT SUSPENSION ASSEMBLY

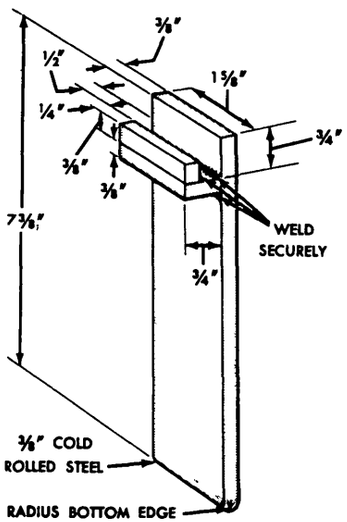
SHOCK ABSORBER REPLACEMENT: Removal - Raise front of car and place supports under both suspension lower arms (make sure lower end of shock absorber is accessible). Disconnect shock absorber lower retaining nuts from spring lower plate, then remove shock absorber upper mounting bracket nuts. Lift bracket and shock absorber out of coil spring. Remove bushings and washers from shock absorber stud and remove shock absorber from bracket.

Installation: Install bushings on lower stud, then install washer and upper bushing. Install bracket, bushing, washer, and retaining nut. Extend shock absorber and install on spring lower retaining plate. Install lower bushings and washers and tighten nuts to 12–17 ft. lbs. Install upper mounting bracket on body and tighten nuts to 8–13 ft. lbs. Tighten shock absorber-to-mounting bracket nut to 15–25 ft. lbs.

FRONT SPRING REPLACEMENT: Removal - Raise car and remove wheel assembly, then remove shock absorber. *CAUTION - Install a safety stand under front end of underbody.* Install Tool 5310-B (Comet), T60K-5310-A (Falcon) in shock absorber lower mounting holes and use tool to compress the spring ½-1". Remove spring lower plate retaining nuts, then lift spring

CONTINUED ON NEXT PAGE

COMET & FALCON FRONT SUSPENSION (Continued)



and plate and remove plate. Guide spring and tool down and out forward end of wheel housing.

Installation: If spring is to be replaced, measure spring height compressed in tool. Place tool nut in vise and remove nut by rotating the spring by hand. Install tool in new spring, then with tool nut in a vise, rotate spring until the previously measured spring height is attained. Guide spring into position (spring lower end installed outside of spring plate). Install spring lower plate retaining nuts, then loosen spring removal tool nut until spring is seated properly, then remove tool. Install shock absorber, wheel and tire, and lower the car.

UPPER BALL JOINT REPLACEMENT (CONTROL ARM IN CAR): Removal – Raise car high enough to provide working space, and place a support under upper arm (see "Support Tool Note" below). Remove wheel and tire, then use a large chisel to cut off the three upper ball joint retaining rivets. Remove upper ball joint from spindle, *see "Front Wheel Spindle Replacement" below.*

Installation: Clean end of arm and remove all burrs from hole edges. Check for cracks in metal at holes, and replace arm if it is cracked. Attach new ball joint to upper arm using the specified bolts, nuts and washers. *CAUTION – DO NOT attempt to rivet new ball joint to arm.* Tighten ball joint attaching nuts to 12–17 ft. lbs.

FRONT WHEEL SPINDLE REPLACEMENT: Removal – Raise car until front wheels clear floor, then place upper assembly support under arm (see "Support Tool Note" below). Remove wheel and drum, then remove backing plate from spindle. *NOTE – Support plate to prevent damage to brake hose.* Disconnect spindle connecting rod end from spindle arm, then remove cotter pins from both ball joint stud nuts, and loosen nuts one or two turns. DO NOT remove nuts from studs at this time. Place a box wrench over lower end of ball joint remover tool, and install tool between upper and lower ball joint studs. Make sure tool seats firmly against ends of both studs and not against stud nuts. Turn wrench until studs are under tension, then tap spindle near studs to loosen them in the spindle. *CAUTION – Do not loosen studs in spindle with tool pressure alone.* Remove stud nuts and spindle from both studs.

UPPER CONTROL ARM SUPPORT TOOL

Installation: Install spindle on both ball joint studs and install stud nuts. Tighten upper and lower stud nuts to 35–65 ft. lbs. Continue to tighten both nuts until cotter pin holes and slots line up, then install new cotter pins. Connect spindle connecting rod end to spindle arm. Install brake backing plate on spindle and tighten bolts to 25–35 ft. lbs. Install wheel and drum and adjust wheel bearing, then check and adjust front wheel alignment.

UPPER CONTROL ARM: Removal – Raise car until front wheels clear floor, then place upper arm support tool under the arm, see "Support Tool Note" below. Remove wheel and tire, then disconnect spindle arm from upper ball joint *(see "Wheel Spindle Replacement" below).* Remove spring, then remove upper arm inner shaft retaining nuts (from engine compartment), and remove upper arm. Measure and note total shim thickness at each inner shaft bolt. *NOTE – Do not wash ball joints with a solvent.*

Inspection: Inspect arm and shaft for cracks, bends, or other damage. Check condition of bushings and rubber seal on ball joint stud. Install the nut on ball joint stud, and turn stud in ball joint with a torque wrench. If turning effort is not within 20–30 inch-pounds, replace the ball joint.

Bushing & Inner Shaft Replacement: *NOTE - Always replace both upper arm bushings if either bushing is worn or damaged.* Remove bolts and washers from both ends of inner shaft, then rotate shaft so that retaining studs can be removed with a soft mallet. Place Tool 3044-AB (Comet); T60K-3044-A3 (Falcon), around inner shaft with rounded end against bushing to be removed and install tool retaining bolts and nuts. *NOTE - Shaft and tool may have to be rotated so tool retaining bolts will not bind on upper arm brace.* Remove bushing from shaft with Tool 3044-AB and 3069-H (Comet); T60K-3044-A2 (Falcon). *NOTE - Be sure tool cup rests squarely against upper arm.* Remove other bushing from shaft using same procedure. Clean ends of shaft and install shaft-to-body retaining studs and install shaft in upper arm. Position Tool 3044-AB (Comet); T60K-3044-A4 (Falcon), on inner shaft with retaining studs through tool and tool tab against upper arm inner edge. Place bushings on each end of inner shaft, then using Tool 3044-AB, 3068 and 3069-H (Comet); T54P-3044-A and details 7 & 8 (Falcon), install bushings with arbor press. Install washers and bolt at each end of shaft and tighten to 40-55 ft. lbs.

Upper Ball Joint Replacement: Remove ball joint from arm. If ball joint is riveted to arm, drill a 1/8" pilot hole completely through each rivet, then drill off rivet head through the pilot hole with a 3/8" drill. Drive rivets out of holes. Clean ends of arms and remove all burrs from hole edges. Check for cracks in metal at holes, and replace arm if it is cracked. Install a new ball joint on arm. *CAUTION – Use only the specified bolts, nuts and washers. DO NOT attempt to rivet the new ball joint to arm.* Tighten ball joint retaining nuts and bolts to 12–17 ft. lbs.

Installation: Position upper arm on underbody mounting bracket, and install but do not tighten the nuts and lockwashers on two inner shaft retaining bolts. *CAUTION – The specified keystone-type lockwashers must be used.* Install adjusting shims on both bolts between inner shaft and underbody. *NOTE – Install the same shim thicknesses that were removed from both bolts during disassembly.* Tighten nuts to 65–90 ft. lbs. Install wheel spindle (see "Wheel Spindle Replacement" above). Tighten bolts on ends of inner shaft to 40–55 ft. lbs.

LOWER CONTROL ARM: Removal – Raise car and remove wheel and tire, then install support tool under upper control arm, see "Support Tool Note" below. Disconnect spindle from lower ball joint stud (see "Wheel Spindle Replacement" above). Remove stabilizer bar and link retaining nut, then remove strut-to-lower arm retaining nuts and bolts. Remove lower arm-to-underbody retaining bolt and remove lower arm.

Inspection: Check ball joint and socket, bushings, and rubber seal on ball joint stud. Inspect rubber bumper on arm. If parts are cracked, worn or damaged, replace them.

Lower Ball Joint Replacement: Remove and install lower ball joint in same manner as for upper ball joint (see above). Tighten lower ball joint attaching bolts to 28–45 ft. lbs. *NOTE – If lower joint must be drilled for strut retaining bolts, use the lower arm holes as a guide, being careful not to elongate holes in lower arm.*

Installation: Position lower arm on underbody, then connect stabilizer bar and link, lower ball joint to spindle, and strut to lower arm. Tighten strut-to-lower arm bolts to 40–55 ft. lbs. and spindle stud nut to 35–65 ft. lbs. Tighten lower arm retaining bolts to 30–40 ft. lbs. Lubricate lower ball joint (do not lubricate lower arm bushings), then remove upper arm supporting tool. Check and adjust front wheel alignment.

STABILIZER REPLACEMENT: Raise car and place supports under both front wheels, then disconnect stabilizer from both lower arms. Disconnect both stabilizer retaining brackets, and remove front crossmember guard, then remove stabilizer. To install, coat necessary parts of stabilizer with a suitable rubber lubricant and slide new insulators onto stabilizer. Connect stabilizer retaining brackets and connect stabilizer to both suspension arms. Tighten capscrews to 12–17 ft. lbs. and the nuts for the special 5/16" bolt to 12–17 ft. lbs. Install front crossmember guard, then remove supports and lower car.

►*UPPER CONTROL ARM SUPPORT TOOL NOTE:* A tool as shown in illustration can be fabricated locally to support upper control arm when removing other parts of the front suspension system. Tool should be installed between underbody ledge and opening in upper control arm, adjacent to ball joint.

CORVAIR FRONT SUSPENSION

C rvair (1960)

DESCRIPTION: Spherical (ball) joint type suspension with ball and socket joint connecting upper and lower control arms to steering knuckles. Coil springs are mounted between lower control arm and tower in front crossmember. Shock absorbers are mounted within coil spring on lower control arm and connected at top to tower in front crossmember. Strut rods are connected between outer ends of lower control arms and brackets that trail back from front crossmember. Caster adjustments are made with this strut rod.

TIRE INFLATION PRESSURE: Cold Tire - 15 lbs. (front), 26 lbs. (rear). **H t Tir** - 18 lbs. (front), 30 lbs. (rear).

ADJUSTMENT: Adjust front wheel alignment using the following sequence:

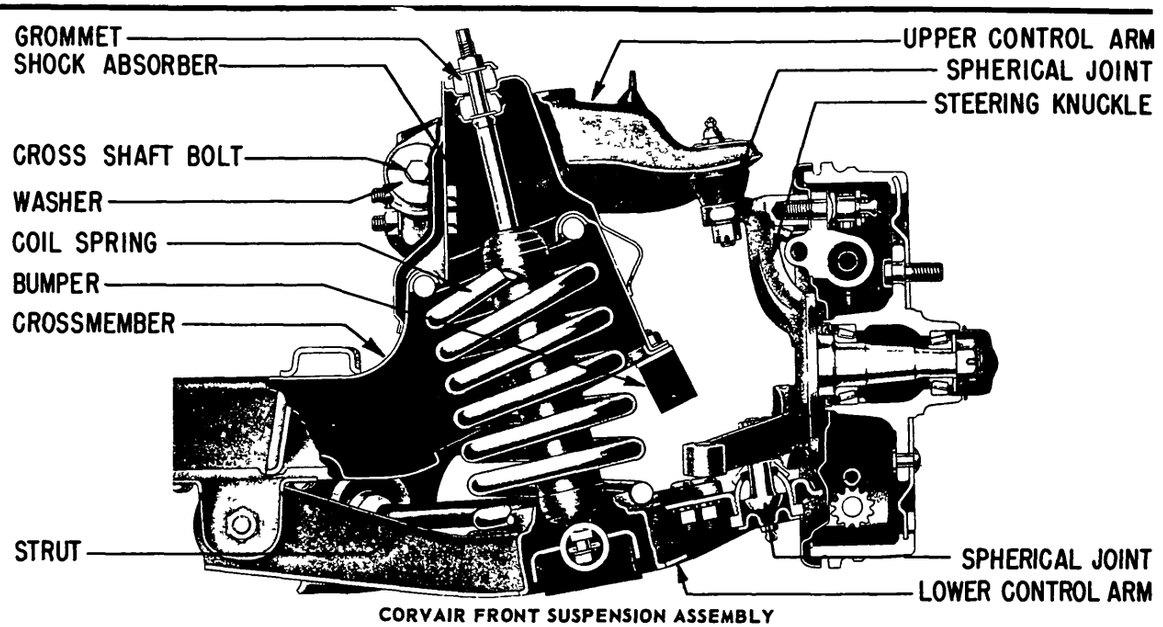
Camb r: Pos ½° ± ½°. Equal within ¼° on both sides of car. Loosen upper support shaft-to-crossmember bolts and add or remove shims as necessary. *NOTE - Shimming must be don equally at both front and rear bolts. Adding shims at both front and rear of support, shaft will d creas positiv camber.*

Cast r: Pos. 4° + 0°, − ½°. Equal within ¼° on both sides of car. Adjust by turning the two nuts at rear of strut rod. Lengthening this rod by turning the nuts increases caster. Shortening the rod by turning the nuts decreases caster. *NOTE - Because of manufacturing tol ranc s, it is p ssibl t run out of threads on strut rod r caus front coil spring to be cocked in its seat and rub spring tow r. Only when this happens is it permissabl to shim un v nly at upper control arm. If shims ar chang d, r ch ck camber.*

Toe-In: 3/16" + 0", − 1/16" (one wheel). 3/8" + 0", − 1/8" (two wheels). Loosen clamp bolts at each end of each tie rod and turn each tie rod sleeve as necessary to obtain proper toe-in with steering gear on "high point" for straight ahead travel.

► *TOE-IN NOTE (REAR WHEELS): A rear wheel toe-in adjustment is n c ssary on these cars. See "Corvair R ar Suspensi n".*

T -Out n Turns: With inner wheel at 33¾°, outer wheel should be at 30°. Not adjustable.



Steering Axis Inclination: 7° at 0° camber. Not adjustable.

Riding H ight: With car at curb weight (full tank of gasoline but an empty front compartment except for spare tire), position car on a smooth, level floor, then bounce and rock car several times and allow it to settle to normal position. Measure distance from floor to bottom of rocker panel 27 inches back from centerline of the front wheel. This measurement should be 9 3/8" ± ½". Measure opposite side of car in the same manner. The difference between the two measurements must not exceed ½". To correct riding height, replace springs. *CAUTION - Th se springs do not have flat ends and shims must not b used.*

► *RIDING HEIGHT NOTE: The above check should be used in conjunction with rear end riding height. See "Corvair R ar Suspension".*

SHOCK ABSORBERS: R m val - Raise front of car so front suspension hangs free and there is sufficient clearance on lower control arms for removal of shock absorbers. Hold shock absorber upper stem on flat section and remove nut, washer and grommet. Remove two lower attaching bolts and withdraw shock absorber.

Installati n: Install cup washer and new grommet on shaft, then pull out shaft to its full length. Install shock absorber up through lower control arm and through coil spring. Make sure shaft protrudes out of small hole in top of spring tower. Install both lower attaching lockwashers and bolts, then hold upper flat and install and tighten nut.

CORVAIR FRONT SUSPENSION ASSEMBLY

SPHERICAL JOINTS: *NOTE - For removal and installation, see below.*

Inspection (Upper): Support car weight at outer end of lower control arm, then remove wheel and tire assembly. Remove cotter pin and nut from upper control arm ball stud and remove stud from steering knuckle with Tool J-6627. Raise control arm to clear knuckle, then install a stud nut on stud and measure the torque required to rotate stud in the assembly with a torque wrench. This should be a minimum of 2 ft. lbs. If excessive wear is indicated in upper joint, both upper and lower joints should be replaced. *NOTE - The maximum allowable torque is 5 ft. lbs. with joint well lubricated.*

Lower - *NOTE - Lower joint is a loose fit in the assembly when not connected to steering knuckle.* If inspection of each upper joint indicates them to be within limits, inspect each lower joint for excessive wear as follows: Support car weight on wheels (or wheel hubs), then with an outside micrometer, measure distance from top of lubrication fitting to bottom of ball stud, and record the dimension for each side. Support car weight at outer end of each lower control arm, so that wheels or hubs are free, then repeat the measurement. If difference in dimension on either side is greater than 3/32", the joint is excessively worn and both lower joints should be replaced. If measurements do not indicate worn joints, check torque tightness of stud nut at each side as follows: Clean nut and cotter pin and check for evidence of looseness of stud in knuckle. If looseness is not indicated, mark stud and nut to identify relative location, then back off stud nut and retighten to original position. Note the torque reading required to tighten nut. If less than 45 ft. lbs., stud may have been loose in knuckle and should be replaced.

FRONT COIL SPRINGS: R m val - Place car on a suitable hoist or jackstands. *NOTE - Front c ntrol arms must be allowed to swing free but must be positioned so they may be raised or lowered with the hoist or a jack.* Remove shock absorbers, then remove the two strut rod-to-control arm nuts and lockwashers (the studs are pressed into end of strut rod). *NOTE - Th strut rods are under slight tension from the rubber grommet on opposite end.* **Loosen but do not remov lower control arm inner pivot nut.** *CAUTION - Do not remove pivot bolt and nut at this time.* Place jack or hoist under control arm and take up slightly on spring compression. If jack is used, place it under inner end of control arm on bushing. Remove control arm pivot nut and lockwasher and tap out pivot pin. Carefully lower hoist until spring is free, then withdraw spring. *NOTE - A bar placed through control arm and into spring tower will retain spring and keep it from slipping until free. Otherwise, keep clear of suspension until all compression is removed from spring.*

Installation: Set rubber spacer in place on top of coil spring and secure with friction tape. *NOTE - Step in spacer must contact end of coil spring.* Place spring on control arm with rubber spacer at top. Rotate spring until upper end of coil makes contact with its seat, then using a jack, raise control arm, line up arm, and bracket and install bolt (from front), nut and washer. DO NOT tighten at this time. *NOTE - A bar placed up through control arms and into tower will retain spring and keep it secure until pivot bolt is installed.* Attach strut rod to control arm and tighten nuts. Install shock absorber, then lower car to floor. Bounce front end several times and tighten lower control arm pivot bolt and nut.

LOWER CONTROL ARM & SPHERICAL JOINT: Removal - Remove coil spring, see above, then remove nut from lower spherical joint. Tap on control arm to remove it and the joint from steering knuckle. If spherical joint is to be removed, place control arm in a vise and use a six point 1 5/8" wrench to remove self-tapping joint from lower control arm. *NOTE - If prop r size wrench*

CONTINUED ON NEXT PAGE

CORVAIR FRONT SUSPENSION (C ntinu d)

is not available, hold joint in a vise and rotate control arm.

Control Arm Bushing Replacement: Use Tools J-7079-2, J-8346-2, J-8346-I, & J-5888-3 and press or hammer bushing out of control arm. *NOTE - Be sure to press on end of bushing that does not have the large collar on outer shell.* To install, use same tools used for removal, entering bushing in control arm from front side.

Installation: If spherical joint was removed, start into control arm by turning, as it is self-tapping. Secure in place with proper size wrench. *NOTE - A small hand press will help to steady spherical joint on installation.* Install lube fitting in bottom of joint and lubricate with chassis lube. Place rubber cap over stud. Install coil spring (see above).

UPPER CONTROL ARM & SPHERICAL JOINT: Removal - Support car weight at outer end of lower control arm, then remove wheel and tire. Remove upper control arm ball stud with Tool J-6627. Remove two nuts retaining upper control arm cross shaft to front crossmember. Note number and thickness of shims at each cross shaft bolt.

Spherical Joint Replacement: Drill through heads of the four rivets securing joint to arm, then use a sharp chisel and cut off rivets, being careful not to enlarge holes in control arm. Tap out rivets and remove from control arm. To install new joint, position it against top side of control arm and secure in place with the special alloy nuts and bolts furnished with service replacement joint. Tighten nuts to 20-25 ft. lbs. *CAUTION - Use only alloy bolts supplied for this operation.*

Cross-Shaft & Bushings: Removal - Remove bolts, washers, and collars from both ends of cross-shaft, then remove rubber spacer from rear end of shaft. Install a same size but longer bolt in end of cross-shaft (opposite side from bushing that is installed outside of arm). *NOTE - This bolt is furnished with Tool J-8345.* Set arm in place in Tool J-5888-3 and press bushing out with an arbor press. Turn control arm over and press out bushing with Tools J-8345-3 and J-7079-2, using Tool J-5888-3 as a support.

Installation - Set control arm in place on Tool J-5888-3, then press bushing into place with Tools J-7079-2 and J-8345-2. *NOTE - Start with bushing that has to be installed from inside of arm.* Install cross shaft in arm, invert in press and press in second bushing with Tools J-8345-1, 8345-2 and J-7079-2. *NOTE - This bushing must be installed from outside arm.* Check to see that cross shaft can be turned by hand. Install rubber spacer on rear end of shaft, then install collar, washer, and bolt in ends of cross-shaft but do not tighten bolt.

Installation (Control Arm): Install new upper control arm shaft-to-front crossmember studs, then install control arm. Install same number and thickness of shims that were removed at disassembly on each bolt. Install a new rubber seal on ball stud and install ball stud through knuckle. Tighten nut securely and install cotter pin. Install wheel assembly and lower car to floor. Bounce front end of car several times to centralize bushings, then tighten cross-shaft bolts to 35-40 ft. lbs. *NOTE - If a new spherical joint was installed or if proper number of shims w r not reinstalled, recheck caster and camber.*

FRONT CROSSMEMBER: *NOTE - Crossmemb r may b removed as either a compl t ass mbly or aft r components have been removed.*

Removal: Raise and support car so front suspension will swing free, then remove both brake pipes from brake hoses and remove hoses from body brackets. Remove nuts securing inner ends of tie rods to relay rods. Support crossmember with a jack or other means that will allow raising and lowering it, then remove the three bolts at each side that attach crossmember to frame (one of the bolts at each side is installed up through strut rod bracket). *CAUTION - B car ful that crossmember does not slip or fall from its supp rt.* Lower crossmember to floor.

Installation: Raise crossmember into position, then align bolt holes with a tapered punch and install the six bolts. *NOTE - Do not tighten any on bolt until all bolts are in position.* Tighten bolts securely. Remove crossmember support or jack and install tie rod studs into relay rod and tighten the nuts securely. Install brake hoses to body brackets and install brake pipes to hoses. Bleed brakes and position hoses properly.

CORVAIR REAR SUSPENSION

Corvair (1960)

DESCRIP TION: Independently sprung with individual single control arm at each side of car. Coil type rear springs are mounted between control arm and frame crossmember. Rear shock absorbers are mounted within coil springs.

ADJUSTMENT: Toe-In: 0" to ¼". *NOTE - If drive-on type equipment is used, reverse car and back it into position. Toe-In (overall) will be read as toe-out (readings taken from rear of tires rather than front).* To adjust, add or remove shims equally at each side of front edge of transmission case (with engine rear support loosened). *CAUTION - Shims must be added or removed qually from each side of transmission. DO NOT attempt to adjust one wheel at a time.* A shim added to each side will increase toe-in. Removal of shim from each side will decrease toe-in. *NOTE - Because of manufacturing tolerances and parts "stack-up" it is possible to have toe-out on one wheel and toe-in on opposite wheel. In this case, adjust the wheel with toe-out as close to specifications as possible but not letting opposite wheel go out of specifications. If for example, one wheel toes-out by ¼", then opposite wheel must toe-in enough to give 0" to ¼" overall toe-in.*

Camber: 1½°±½°. Not adjustable. If camber is not within limits, either the crossmember is out of alignment with the body or has become distorted due to collision.

Rear Riding Height: With car at curb weight (full tank of gasoline but an empty front compartment except for spare tire), position car on a smooth, level floor, then bounce rear end several times and allow it to settle to its normal height. Measure distance from floor to bottom of the rocker panel 29" ahead of centerline of rear wheel. This measurement should be 9" ±½". Measure opposite side of car in the same manner. The difference between the two measurements must not exceed ½". To correct riding height, replace springs. *CAUTION - These springs do not have flat ends and shims must not be used.*

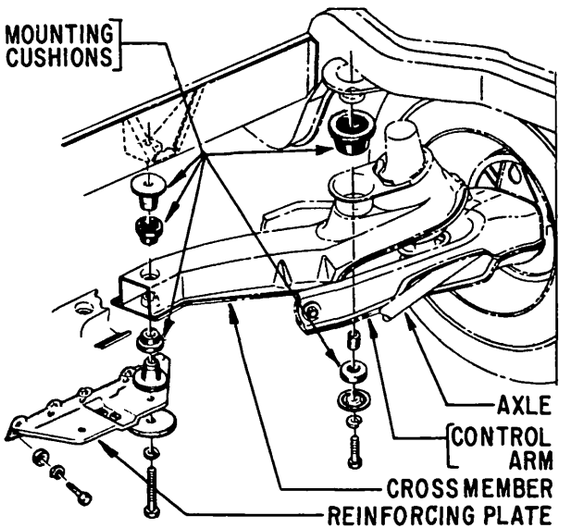
► *RIDING HEIGHT NOTE: The above check should be used in conjunction with front end riding height. See "Corvair Front Suspension".*

COIL SPRING: Removal - Raise car by body side rails so control arms swing free. *NOTE - Raise car high enough for a rolling floor jack to be placed under the brake drum.* Loosen control arm cross-shaft bolts (in ends of shaft), then remove bolt that holds brake hose bracket to underbody. *NOTE - It may be necessary to disconnect and plug fuel line and heater fuel line (on left side only).* Remove wheel, then replace wheel stud nuts to hold drum in place. Position axle shaft so side surface of universal joint yoke is at an angle of 45° to centerline of axle case (this must be done to allow axle shaft and control arm to swing down far enough to remove spring. Otherwise, universal joint yoke would strike axle case or side bearing adjusting nut). Place a rolling floor jack under brake drum and flange, then raise jack slightly to place a light load on coil spring. Remove two bolts and lockwashers securing bottom of shock absorber to control arm, then remove upper attaching nut, washer and grommet. Remove shock absorber. Carefully lower floor jack until spring is free. *CAUTION* - Do not remove or lower jack too far as this places too much strain on axle shaft and/or brake hose.

Installation: Set spring in place on lower control arm and rotate spring until it seats against step in crossmember. Extend shock absorber shaft, then place it up through control arm and spring and attach bottom of shock absorber to control arm. *NOTE* - Installing shock absorber at this time will give safer working conditions in case jack was not securely placed. Raise control arm until shock absorber top attaching nut, washer and grommet may be installed. Connect fuel line and heater supply line (if removed) and attach brake pipe bracket to underbody. Remove floor jack and install wheel. Lower car to floor and bounce rear end several times with full weight on suspension control arms, then tighten cross-shaft bolts to 45-55 ft. lbs.

SHOCK ABSORBERS: *CAUTION - Th r ar shock absorbers hold all of the rear spring compr ssion. For this reason, the weight of th car must b r sting n the tires during removal. If an attempt is mad to support car on rear suspension low r control arms, and unless proper support is giv n to control arm, it is possible that when shock absorbers ar removed the car may tend to rise up at the rear or control arms may be forced downward, causing car to slip from support. If car is supported at body sid rails and no support is given to wheels and control arm, and the shock absorber is removed, spring pr ssur would force control arm downward and inward with extrem forc .*

Removal: Place car on drive-on (ramp) type hoist, frame contact hoist, or place jack stands under the body at each side rail, just forward of rear wheel openings. The body should be raised high enough so that wheels hang free and so that a floor jack can be placed under tire. With a second jack, raise tire so that it is in its normal position (this will allow shock to be removed without interfering with floor). Hold shock absorber upper stem on flat section and remove upper attaching nut, cup washer and grommet. Remove shock absorber lower attaching bolts, then withdraw shock absorber.

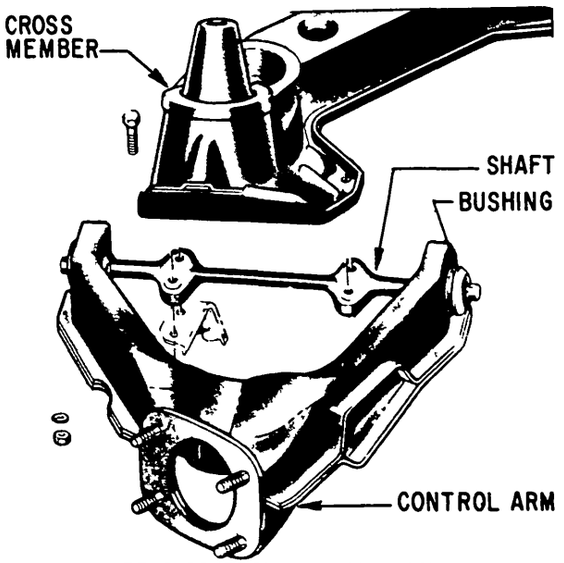


Installation: Install cup washer and new grommet on shaft, then pull out shaft to its full length. Install shock absorber up through control arm and through coil spring. Make sure shaft protrudes through small hole in top of spring tower. Install both lower attaching bolts and lockwashers, then hold upper flat and install and tighten nut.

CONTINUED ON NEXT PAGE

CORVAIR REAR SUSPENSION (C ntinu d)

CONTROL ARM: R m val - Remove coil spring, see above, then before removing jack from under brake drum, support control arm with a suitable jack stand. *CAUTION - D not place a strain on brake hose.* Remove wheel nuts from axle shaft and remove brake drum. Place upper end of brake shoe (still assembled and attached to backing plate) onto brake anchor (this will allow axle flange plate and axle shaft to be pulled out past parking brake strut). Line up hole in axle shaft flange with nuts retaining backing plate to lower control arm, then remove these four nuts and lockwashers. Pry between axle flange plate and backing plate until axle shaft and universal joint assembly can be pulled out of axle case. Remove nuts and washers securing universal joint "U" bolts and remove "U" bolts. Remove bolt, washer, and flat spacer from end of axle shaft. Remove universal joint yoke with Tool J-5504 and withdraw axle shaft. Remove backing plate from control arm studs and wire backing plate to crossmember. Remove bolts, nuts, and lockwashers attaching control arm to crossmember and remove control arm. *NOTE - A parking brake cable bracket is retained by tw of th s bolts.*



Bushings & Cr ss-Shaft: Removal - Remove bolt, lockwasher and collar from each end of shaft, then thread large bolt (furnished with Tool J-8347) to bottom of threads in one end of cross-shaft. Support control arm in press on Tool J-5888-3 and install Tool J-8347 between arms of control arm assembly, then press on bolt until bushing is free of control arm. Remove bolt from end of shaft and insert it in opposite end and invert control arm on Tool J-5888-3, then press bushing out of control arm and remove cross-shaft. *NOTE - Be sure that bushing flang does not contact support tool during pr ssing op ration.*

REAR SUSPENSION ASSEMBLY MOUNTING

Installation - With cross-shaft in control arm and Tool J-8347 in position, Place control arm on Tool J-5888-3. Hand start bushing into control arm and over end of cross-shaft. Install Tool J-7052-5 over bushing (be sure that Tool J-8347 is not overlapping bushing holes in control arm), then press bushing into control arm until flange contacts control arm. *NOTE - In some instances it may be necessary to shim under Tool J-8347 to assure proper contact with both flanges of control arm.* Invert arm in press and repeat the above process on opposite bushing. After installation, cross-shaft should be free enough to turn by hand. Install collar, lockwasher, and bolt in each end of cross-shaft. DO NOT TIGHTEN NUTS until after coil spring installed.

Installation (Control Arm): Set control arm assembly in place on crossmember, then install attaching bolts, lockwashers and nuts. *NOTE - Be sure to attach parking brake bracket to front two attaching bolts.* Replace jack stand under control arm. Remove brake backing plate from crossmember and check to make sure axle shaft oil slinger is in place (small drain hole at bottom), then install backing plate on studs in end of control arm. Temporarily install two nuts on studs. Install axle shaft through backing plate and control arm, then install yoke on end of axle shaft. Install flat spacer, lockwasher and bolt that retains yoke to shaft. Install universal joint "U" bolts, nuts and lockwashers. Remove the two temporarily installed backing plate nuts, then install universal joint spline into axle housing (be careful of seal). *NOTE - Properly position brake shoe on anchor.* Line up holes in axle bearing flange plate with studs on end of control arm, then install lockwashers and nuts through hole in axle shaft flange. Install drum onto axle flange being certain that holes (not stud holes, but machine holes) in drum DO NOT line up with hole in axle flange. Temporarily install wheel nuts to hold drum in plate. Install shock absorber and coil spring (see above).

REAR CONTROL ARM ASSEMBLY

REAR SUSPENSION CROSSMEMBER: R m val - Remove both shock absorbers and coil springs (see above), then support control arms with jack stands. Disconnect parking brake cable at rear equalizer and disconnect transmission linkage or remove clutch cross-shaft. Remove brake pipe from brake hose (both sides) and remove speedometer cable bracket on underbody. Remove four bolts attaching control arm to crossmember (let parking brake cable bracket hang free), then remove jack stands from under control arms. Support control arm assembly by hand, then pull control arm (with drum and axle shaft still assembled) outward to remove axle assembly from axle case. Repeat for opposite side of car. Place a hydraulic floor jack under axle housing to support power train when front (toward front of car) mounting is removed. Remove two inner crossmember-to-body attaching bolts, lockwashers and thick metal washers. *NOTE - The rubber and metal conical shaped spacers will probably remain with crossmember.* Remove four bolts retaining mounting bracket to transmission and note the number of shims removed at each point. Remove two nuts and lockwashers attaching bracket to crossmember and remove bracket. Remove reinforcing plate between crossmember and body, noting the number of shims removed at plate mounting. Remove bolt, lockwasher, large "dished" washer and rubber spacer from both sides of crossmember, then carefully lower crossmember to floor by "rolling" it slightly forward and pulling (not bending) transmission accelerator control rod to one side (if so equipped).

Installation: If necessary, tape crossmember outer mounts in place, then set crossmember in place and install outer mounts to body (do not tighten). Install reinforcing plate between body and crossmember (do not tighten). Loosely install power plant brace to crossmember, then install four bolts and tighten to 20-30 ft. lbs. *NOTE - Coat threads with "anti-seize compound" and install the same number of shims as removed at each bolt location.* Tighten crossmember outer mounting bolts securely, then install and tighten inner attaching mounts. Tighten the two bolts attaching brace and mounts to crossmember. Replace the same number of shims between body and reinforcing plate as removed. *NOTE - Shims are available in 1/32", 1/16", 1/8" sizes to fill gap between body floor pan and reinforcing plate.* Tighten attaching bolts on reinforcing plate between body and crossmember. Remove jack from under axle housing, then install clutch and transmission linkage except accelerator control rod (if used). Install speedometer cable bracket to underbody, then place two rear control arm assemblies under car (these are still attached together by parking brake cable). Pick up one control arm assembly (axle shaft assembly and brake assembly still attached) and place universal joint into axle case being careful not to damage seal. Place a jack stand under the control arm to support it and install four control arm attaching bolts, lockwashers and nuts (make sure parking brake bracket is in place) and tighten to 40-50 ft. lbs. Pull parking brake cable (one attached to each brake assembly) up over transmission accelerator control and hook up control. Install opposite arm assembly in same manner as for first assembly (see above). Install transmission or clutch linkage (if removed), then hook up brake pipe and position brake hose. Install rear coil springs and shock absorbers (see above). Bleed brakes and check rear wheel toe-in.

1954-56 FORD PASS. CARS LINCOLN, MERCURY

Continental (1956)
Ford Pass. Cars (1954-56)
Lincoln (1954-56)
Mercury (1954-56)
Thunderbird (1955-56)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 FORD LOWER ARM BUMPER ASSEMBLY INSTALLATION CAUTION:* Bumpers are supplied as right-hand (AD-3019-B) and left-hand (AD-3020-B) and are designed to point slightly inboard when correctly installed If right-hand bumper installed on left side or vice versa, bumper will not contact frame on rebound and serious damage to the suspension may result

►*1955 FORD CAR & THUNDERBIRD LOWER ARM MOUNTING BOLT BUSHING INSTALLATION CAUTION* Double-shoulder front suspension lower arm mounting bolt bushing (Part No B4A-3069-D) was released for use on Ford cars and Thunderbird but **was not** used in production Bushing used in production is single-shouldered The front bushing is pressed in from the inside of the lower arm front leg

►*1955 FORD FRONT SPRING SHIM INSTALLATION (When Air Conditioning Unit Installed):* Spring shim and rubber insulator (Part No AD-5355-A) should be installed on top of front springs when air conditioning unit is installed in the field in order to maintain front end and ride height

►*1955 FORD STABILIZER & SHOCK ABSORBER LOCKNUT PRODUCTION CHANGE* To prevent possibility of locknut (45218-S) from coming loose from stabilizer link and shock absorbers, locknut has been eliminated and a lockwasher (34920-S7) has been added. Torque nut and lockwasher to 15-25 ft lbs. Specification for locknut (45218-S) remains 25-35 ft lbs.

►*LUBRICATION CAUTION* DO NOT use any type of lubricant on rubber bushings at inner ends of upper and lower control arms Upper and lower ball joint assemblies are only points requiring lubrication

►*1955-56 FORD LOOSE UPPER SUSPENSION ARM CORRECTION:* When loose upper suspension arm bolts are found, remove old lockwashers and install reverse keystone lockwashers (Part No 357626-S7) Tighten bolts to 65-90 ft. lbs.

►*1955 FORD UPPER BALL JOINT STUD TIGHTENING CORRECTION (Due to Too Short Ball Joint Stud):* To correct, use Lockwasher, Part No. 34850-S7, as a spacer between nut and spindle. Tighten nut to 60-80 ft. lbs.

►*1954-56 LINCOLN REBOUND "THUMP" CORRECTION:* Install Bumper, Part No LD-3025-A These bumpers have a flat surface on top and are designed to correct "thump" condition Replace bumpers in pairs only

DESCRIPTION: "Ball-Joint" type with direct acting shock absorbers mounted within front coil springs

CHECKING & ADJUSTMENT: Check wheel bearing adjustment, wheel spindle wear, tire inflation pressure, wheel runout and balance Check steering linkage, and steering gear for excessive looseness or play, then place car on level floor and check front end specifications with car at curb weight

►*ADJUSTMENT CAUTION Due to differenc s in mounting of upper support arm shaft and location of adjusting shims, all models are not adjusted exactly alike. See Adjustment data following:*

Tire Inflation Pressure For each tire size and model (Cold)

FORD

Model	Tire Size	Lbs. Press. Front	Rear
Conv with Fordomatic (1954)	7 10x15-4	24	21
Victoria, Fordomatic (1954)	7 10x15-4	24	21
Fairlane 8, Fordo (1955)	6 00x16-4	28	25

C — 30 lbs at sustained high speed

►*THUNDERBIRD CASTER & CAMBER ADJUSTMENT: Addition or removal of shims for caster and camber adjustment on Thunderbird cars produces effect reverse to that on other Ford cars.*

Kingpin Inclination: 6-7° (Ford & Thunderbird). 7°10" (Lincoln), 7° (Continental & Mercury) with Pos. ¾° camber.

Caster: Continental - Pos 1°±¼° with ½° variation limit. Ford (1954-55) - 0° to Pos 1°, (1956) Pos ½° to Pos 1½° with ½° variation limit Lincoln & Mercury - 0° to Neg 1½° with ½° variation limit

Adjustment (Ford)—Loosen two bolts attaching upper support arm shaft to frame bracket, remove or insert shims at one or the other mounting bolt. **These shims located between inner side of shaft and frame bracket.** To INCREASE POSITIVE CASTER, add shim at front bolt or remove shim at rear bolt. To INCREASE NEGATIVE CASTER, remove shim at front bolt or add shim at rear bolt. A 1/16" shim thickness change at either point will change caster ½°. Shims furnished in thicknesses of 1/32" & 1/16". Check Camber. After adjustments completed, tighten shaft bolts to 65-90 ft. lbs.

►*CAUTION—Difference in thickness of shim pack at front and rear bolts must not exceed 1/8".*

Adjustment (Lincoln & Mercury)—Loosen two bolts attaching upper support arm shaft to frame bracket, insert shims at one or the other mounting bolt **These shims locat d b tw n uter sid f shaft and fram brack t.** For POSITIVE CASTER INCREASE, add shim at rear bolt (or remove shim at front bolt), for NEGATIVE CASTER INCREASE, add shim at front bolt (or remove shim at rear bolt) A 1/16" shim thickness change will change caster ½°. Shims furnished in thicknesses of 1/32" and 1/8" (also 1/64" and 1/16" for Lincoln). Check Camber After adjustments completed, tighten shaft bolts to 75-90 ft. lbs. (Lincoln), 70-80 ft. lbs. (Mercury).

Camber: Continental Pos. ¾°±¼°. Ford Pos. ¼° to Pos. 1¼° with variation limit of ¼°. Lincoln & Mercury 0° to Pos. ¾° with ¼° variation limit.

Adjustment (Ford)—Procedure is same as for Caster Adjustment above except that shims should be added or removed equally at both front and rear bolts. For POSITIVE CAMBER INCREASE, add shims equally at both bolts; for NEGATIVE CAMBER INCREASE, remove shims equally at both bolts. A 1/16" shim thickness change will change camber ¼°. After adjustment completed, tighten shaft bolts to 65-90 ft. lbs. torque.

►*CAUTION—Total shim pack thickness at each bolt should not exceed 9/16".*

Adjustment (Lincoln & Mercury)—Procedure is sam as for Caster Adjustment above xcept that shims should be added or removed equally at both front and rear bolts. For POSITIVE CAMBER INCREASE, remove shims equally at both bolts; for NEGATIVE CAMBER INCREASE, add shims equally at both bolts. A 1/16" shim thickness change will change camber ¼°. After adjustment completed, tighten shaft bolts to 75-90 ft. lbs. (Lincoln), 70-80 ft. lbs. (Mercury).

Toe-In: 3/32-5/32" (Continental & Mercury), 1/16-1/8" (Ford), 3/32-3/16" (1954-55 Lincoln), 1/8-3/16" (1956 Lincoln)

►*1954-56 MERCURY POWER STEERING CONTROL VALVE INTERFERENCE CAUTION:* Use caution when installing the left hand drag link adjusting sleeve. Clamps should be installed with the bolts in a vertical position and forward of the steering link. If clamps are installed with bolts to the rear, or horizontal, it is possible for them to interfere with the power steering valve assembly

Adjustment (All Models)—Loosen clamp bolts n adjusting sleeve at outer end of each tie rod, turn both adjusting sleeves equally f r correct toe-in (turn sleeves in opposite directions).

►*CAUTION—On Power Steering cars, run engine whil adjusting toe-in to insure contr l valv being properly centered in pitman arm end f steering arm-to-idler arm rod.*

Toe-Out on Turns: Inner and outer wheel angles are shown below. No adjustment.

Toe-out Sp cificati ns

	Inn r	Outer
Continental (1956) G	36°	26°
Lincoln (1954-55)	23½°	20°
Lincoln (1956) G	36°	26°
Mercury (1954)	24°	20°
Mercury (1955)	24°9'	20°
Mercury (1956 Exc Conv) G	38°	27°40'
Mercury (1956 Conv) G	36°	26°50'

G - Maximum turning angle

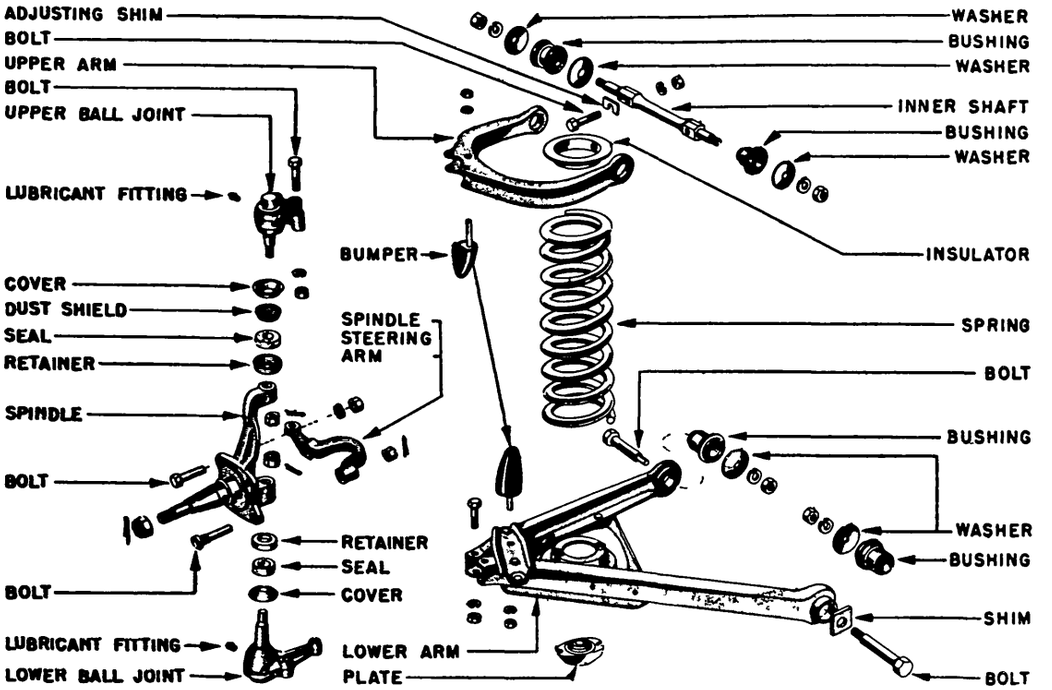
1954-56 FORD PASS. CARS LINCOLN & MERCURY (C nt.)



SHOCK ABSORBER REPLACEMENT: Not necessary to disturb front suspension assembly. Remove two nuts on mounting studs which hold shock absorber mounting plate on under side of spring seat on lower control arm. Remove nut on shock absorber stud at upper end of shock absorber, lower shock through hole in spring seat.

Installati n: Reverse removal procedure. Make certain that rubber bushings and washers installed in correct position, tighten shock absorber stud nuts to 20-35 ft lbs. (Ford), 20-30 ft. lbs. (Lincoln & Mercury). Tighten shock absorber mounting plate-to-lower support arm capscrews to 12-20 ft lbs. (Ford), 13-18 ft lbs. (Lincoln & Mercury).

COIL SPRING & LOWER SUSPENSION ARM REPLACEMENT (Rem val): Raise front of car and place support stand under each frame side rail to rear of lower suspension arm. Remove front wheel, hub, and drum as an assembly. Remove shock absorber (above), disconnect stabilizer bar from lower suspension arm. Loosen lower ball-joint to wheel spindle stud nut approximately two turns and loosen ball-joint (see "Ball-Joint Removal" below) Place a jack under lower suspension arm and raise arm until rebound bumper on upper arm is clear of the frame. Remove nut from lower ball-joint stud and lift wheel spindle up and off the stud. Lower jack until spring tension is relieved and spring can be removed. Remove coil spring, rubber insulator and retainer ring (Note location of these parts to insure correct reassembly). To remove lower suspension arm, take out the two bolts attaching arm to frame. Inspect bushings on inner end of each member and replace if necessary.

Bushing R plac m nt (Lincoln & Mercury)—Position Split Adapter Ring Tool 3069-F on inside of inner end of rear (short) arm and place Tool 3069 to fit into groove of Tool 3069-F. Place Tool 3069-G over the bushing. Press bushing from arm with an arbor press to remove bushing from the front (long) arm, position flange of inner bushing in Tool 3069 and place Tool 3069-G over the bushing. Press bushing from arm To install bushings, center bushings in arm hole and place bushing flange on Tool 3069-A (Lincoln), 3069-E (Mercury), then place Tool 3069 over arm Press bushings in place Tool 3069 over the arm Press bushings into place until shoulder ribs of bushing bottom on suspension arm (do not attempt to press bushing beyond edge of shoulder ribs or raised section of outer sleeve as distortion will result). *CAUTION—Under no circumstances should only on bushing be replaced .*

Bushing Installati n (F rd)—Use Tool T54P-3044 to install bushings (this tool is composed of a number of various parts and each part is referred to as a "Detail #6" etc.). Position both halves of Detail #12 on inside of inner end of rear (short) arm and place Detail #6 to fit into groove of Detail #12 Place Detail #5 over the bushing and press bushing from arm with an arbor press To remove bushing from front (long) arm, position flange of inner bushing in Detail #6 and place Detail #5 over bushing and press bushing from arm. To install bushings, center the bushings in the arm hole and place bushing flange on Detail #7, and then place Detail #6 over the arm. Press bushing into place until shoulder ribs of bushing bottom on suspension arm (Do not attempt to press bushing beyond edge of shoulder ribs or raised section of outer sleeve as distortion will result). *CAUTION—Under no circumstances should only* one bushing be replaced.

LINCOLN & MERCURY "BALL JOINT" FRONT SUSPENSION

Installation: Install the lower arm rear leg to frame cross member and tighten attaching nuts to 55-75 ft lbs torque Add enough shims between forward arm and frame to fill the existing space, and tighten nut finger tight Loosen nut on rear arm and run it up finger tight With the arm in curb load position (approximately horizontal with outer ends slightly lower than inner) torque the attaching nuts to 55-75 ft lbs Place coil spring and upper rubber insulator in position With a jack under the lower suspension arm, raise arm to compress coil spring Care must be taken so that both upper and lower ends of spring are properly seated Guide the spindle boss over ball joint stud Install nut and torque to 100 ft lbs , continue to tighten until cotter pin hole is lined up install cotter pin Remove jack from under suspension arm, and install shock absorber Secure stabilizer to lower suspension arm with spacer, insulator, washers, and bolt Install wheel and hub assembly and adjust front wheel alignment

BALL-JOINT REMOVAL (Upper & Lower): Ball-joints are furnished as assemblies except for seals and related parts assembled on ball-joint stud. Raise front of car with a jack placed under lower control arm, then place a support under frame side rail to rear of suspension arm. Remove front wheel and remove cotter pin in ball-joint stud (NOTE—If both ball-joints are to be removed, free the lower stud first). Loosen stud hex nut approximately 2 turns and install Tool 3006-A with the screw end resting against lower stud nut. Turn screw of tool and apply sufficient pressure to place ball-joint under tension Strike the spindle sharply at a point opposite the stud bore to pop it loose Increase tension and strike again if necessary *(CAUTION—Spindle or tool may be damaged if pressure only is used to free stud)* Repeat this procedure with other stud if it is to be removed Ball-joint assembly can be removed from suspension arm by taking out the three attaching bolts

Servicing—Remove retainer, seal, and covers from stud, inspect parts for wear or damage and replace if necessary If new rubber seals being installed, see that they are pushed down into retainer cup before cup

CONTINUED ON NEXT PAGE

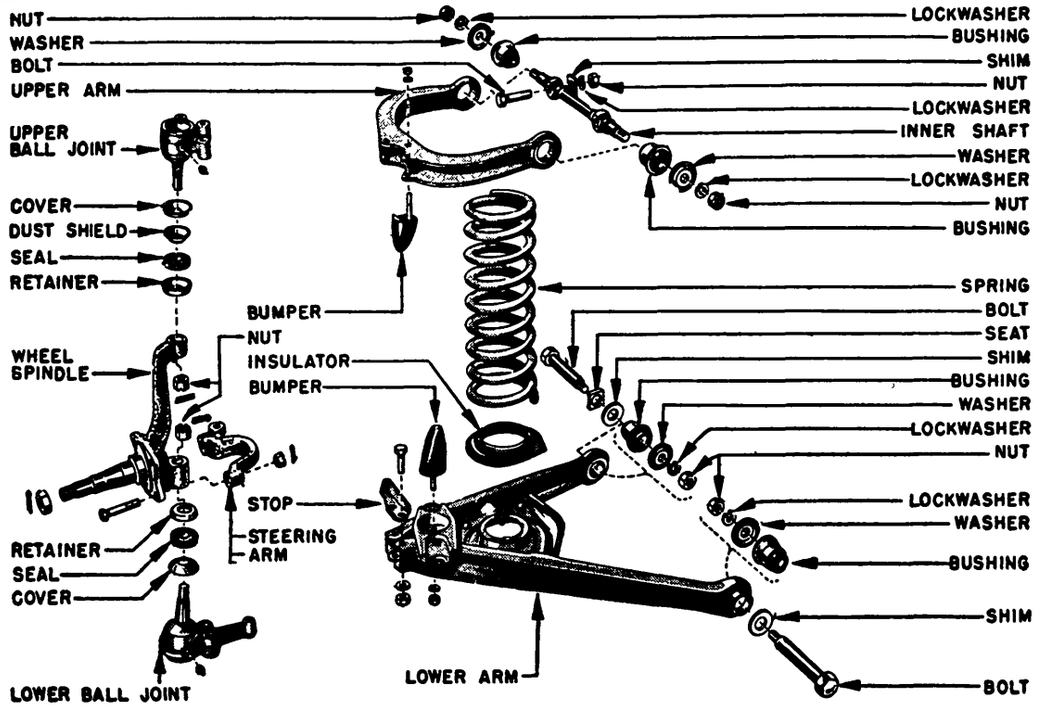
1954-56 FORD PASS. CARS LINCOLN & MERCURY (C nt.)

is installed on stud. Reassemble all seal parts in original position.

►*CAUTION—Do. not wash ball-joint assemblies with solvent which may remove lubricant.*

Installation—Reverse removal procedure as given above. Tighten to following torques:

Ball-Joint Assembly Mounting Bolts



Car	Upper	Lower
Ford	28-43 ft. lbs.	65-90 ft. lbs.
Lincoln & Mercury	30-40 ft. lbs.	70-90 ft. lbs.

Ball-Joint Mounting Stud Nuts—Tighten stud nuts to minimum torque of 80 ft. lbs. (upper ball-joint), 100 ft. lbs. (lower ball-joint), and then continue to tighten until cotter pin holes line up.

UPPER SUSPENSION ARM REPLACEMENT (Removal): Place jack under lower suspension arm near ball joint mounting and raise lower arm until some of the tension has been removed from the upper bumper. Remove wheel and tire assembly. Wire spindle to frame to avoid damage to brake hose. Remove cotter pin from ball-joint stud and loosen nut approximately two turns. Loosen ball -joint stud (see "Ball-Joint Removal" above), then remove ball-joint stud hex nut. Remove the two bolts securing inner shaft to frame (NOTE—Check the number of shims removed from between shaft and frame (Lincoln & Mercury), or between nut and frame (Ford), at each end of bolt locations). Remove upper suspension arm.

Bushing Replacement (Lincoln & Mercury)— Install Tool 3044-B on the inner shaft and place Tool 3069 over bushing. Press bushing from arm. Remove inner shaft and steel washer. To remove the opposite (double shoulder) bushing, on the rear upper arm, insert Tool 3069-F into flange of arm, then place Tool 3069 over bushing and into recess of Tool 3069-F. Center bushing over Tool 3069-G and press out. (NOTE—Tool 3069-G will shear rubber until steel shell is contacted). To install double shouldered bushing in rear of upper arm, lubricate rubber portion of bushing for easier installation. Position Tool 3069 on inner side of rear arm. Install bushing in hole from outer side of arm, position tool 3068 (Lincoln), 3068-C (Mercury) over bushing. Press bushing into arm to shoulder stop. Install long machined end of inner shaft, with washer on shaft, into bushing. Install bushing on front arm, positioning it over end of shaft and pressing it into place with Tool 3068. With both bushings in place, install washer and nut on each end of shaft and tighten finger tight. Position shaft in suspension arm so that holes are parallel with shaft and tighten nuts to 55-75 ft. lbs. torque. *CAUTION—Under no circumstances should only one bushing be replaced.*

►*FORD TOOL T54P-3044-A (Detail #10) REWORK TO AVOID INTERFERENCE:* If interference between upper suspension arm rod and "Detail#10", correct by grinding a 1/8" radius on bottom inner edge of each half of tool, blending it into the flat portion of tool. A pencil type grinder should be used for this purpose.

FORD "BALL JOINT" FRONT SUSPENSION

Bushing Replacement (Ford)—Remove front bushing first. Install Tool 3044-A Detail #10 (see Note above) on the inner shaft and place Detail #6 over bushing. Press bushing from arm. Remove inner shaft and steel washer. To remove opposite (double shoulder) bushing, on the rear upper arm, install Detail #6 over bushing and center bushing over Detail #9. Press bushing from arm. To install double shouldered bushing in rear of upper arm, install Detail #6 on inner side of rear arm. Install bushing in hole (entering it from outer side of arm), and position Detail #9 over bushing. Press bushing into arm until shoulder stop is reached. Install long machined end of inner shaft, with washer on shaft, into bushing. Install bushing on front arm, positioning it over end of shaft and pressing it into place with Detail #8. With both bushings in place, install washer and nut on each end of shaft and tighten finger tight. Position shaft in suspension arm so that holes are parallel with shaft and tighten nuts to 55-75 ft. lbs. torque. *CAUTION—Under no circumstances should only one bushing be replaced.*

Installation: Position the upper suspension arm on frame cross member. Install inner shaft-to-frame bolts and insert the same number of shims that were originally used between shaft and frame cross member (Lincoln & Mercury), between inner shaft attaching nut and frame cross member (Ford). Tighten bolts to 70-90 ft. lbs. torque. Place ball joint stud in spindle and install the the nut. Tighten to 80 ft. lbs. minimum, then continue to tighten until cotter pin holes line up.

1957-60 EDSEL, FORD, MERCURY

Eds l (1958-60)
F rd (1957-60)
Mercury (1957-60)
Thunderbird (1958-60)

►CHANGES, CAUTIONS, CORRECTIONS

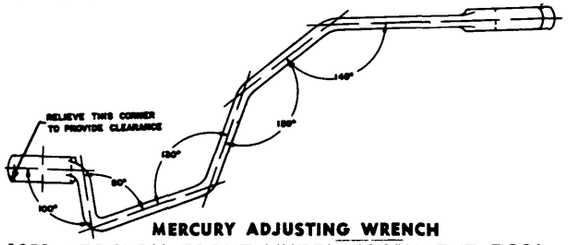
►*1957 LOWER BALL JOINT CHANGE & CHECKING NOTE.* Lower ball joints are not spring loaded and as a result, when there is no load on wheel, a slight looseness will be apparent that is entirely normal *See "Lower Ball Joint" below.*

►*1957 MERCURY STABILIZER BAR INTERFERENCE WITH FRAME CORRECTION.* Loosen the two stabilizer bar-to-frame brackets and slide the two rubber mounting insulators along stabilizer bar as necessary to center the bar Tighten clamps and check clearance between bar and frame. If clearance cannot be obtained in the above manner, replace stabilizer bar *CAUTION - Do not apply heat to bar.*

►*1957 MERCURY "RUBBING" NOISE CORRECTION:* A metallic rubbing noise in front suspension may be caused by the coil spring upper shim being installed without a shim locator allowing shim and spring to shift out of frame pocket Check clearance between outboard side of coil spring and spring pocket by jacking car up with the jack placed under car frame or crossmember (spring extended) If spring is found to be contacting the spring pocket, remove spring and shim and reinstall with a shim locator

►*1958 FORD FRONT COIL SPRING SQUEAKING CORRECTION* This condition may be caused by interference between side of spring seat depression in lower control arm and spring Correct by hammering the the point of interference down sufficiently to allow spring to seat in control arm

►*1958 EDSEL UPPER CONTROL ARM INNER SHAFT PIVOT BUSHING PRODUCTION CHANGE* The rubber bushings formerly used at this location have been changed to permanently lubricated steel threaded type bushings Removal procedures for later type bushings are as indicated below For removal and installation of early type bushings, see "Ford (Except Thunderbird) and Mercury Front Suspension" in 1957 Annual Data



►*1958 MERCURY FRONT SUSPENSION NOISE CORRECTION & PRODUCTION CHANGE* On cars built before December 10, 1957, install a teflon washer, Part No 371139-S between lower suspension arm front bushing and front mounting shim bolt to prevent bushing sleeve rubbing on lower arm Cars built after the above date have the teflon washer installed

►*1958 MERCURY LOWER SUSPENSION ARM FRONT MOUNTING BOLT NOISE CORRECTION* This bolt may be rubbing on front stabilizer bar due to the bolt being too long On some early cars, a 7½" bolt was used at this location, instead of a 7 11/32" bolt Correct by cutting 5/32" from end of bolt

►*1958 MERCURY LOWER CONTROL ARM BALL JOINT NOTE* This ball joint is not spring loaded and will appear to have excessive movement when wheel is shaken (car on a jack) This movement is normal and does not affect operation of joint

►*1958 MERCURY FRONT UPPER CONTROL ARM SQUEAK CORRECTION & "O" RING SEAL PRODUCTION CHANGE* A squeak at this point may be caused by lubricant loss at the threaded pivot bushing due to damage to the "O" ring seal To correct, install "O" ring Seal, Part No 370367-S100 which is being used in later production cars If squeak is not corrected with the new "O" ring replace threaded bushing. *CAUTION - Excess grease at this point can caus seal failure*

►*1958 MERCURY CAMBER & CASTER ADJUSTMENT TOOL NOTE* A special wrench can be made from a 10-12" long 3 4" box end wrench (see illustration below) to aid in reaching the upper arm inner shaft-to-frame bolts

MERCURY ADJUSTING WRENCH

►*1959 MERCURY FRONT WHEEL ALIGNMENT TOOL NOTE* A tool made from a battery hold down bolt, Part No B5A-10756-BUP can be made as indicated in illustration The use of this tool will eliminate the necessity of holding the adjustment bolt during alignment adjustments *NOTE - On some early cars, the holes in frame bracket are ¼" diameter and the tool cannot be used See "Adjustment" below*

►*1959 MERCURY FRONT SUSPENSION "CLUNKING" NOISE CORRECTION* This condition may be caused by interference between stabilizer bar attaching bolt and jounce bumper bracket If stabilizer bar attaching bolt and rubber bushing show signs of wear caused by interference with bracket, measure the distance between bracket and frame gauge hole (gauge hole is approximately ¾" diameter and is located on front face of front suspension crossmember), this distance, measured on a straight line, should be at least 12¾" If bracket is out of location, carefully chisel off and relocate 12¾-13¼" from frame gauge hole Arc weld to frame front, rear, and outside edges

►*1959-60 MERCURY UPPER SUSPENSION ARM SPACER TOOL NO. 3082-A REWORK:* This tool which is designed for previous models may be reworked for use on 1959-60 models as follows Elongate each of the bolt holes at end of tool with a ½" round file Edge of hole should be extended to a point 2 20" from end of tool Grind or file a 1/8" notch (using a round file) in edge of each of the four washers

DESCRIPTION: "Ball-joint" type suspension with shock absorbers mounted adjacent to coil spring between lower control arms and brackets on frame side rails Rubber type bushings are used to connect lower

CONTINUED ON NEXT PAGE

1957-60 EDSEL, FORD, MERCURY (C ntinu d)

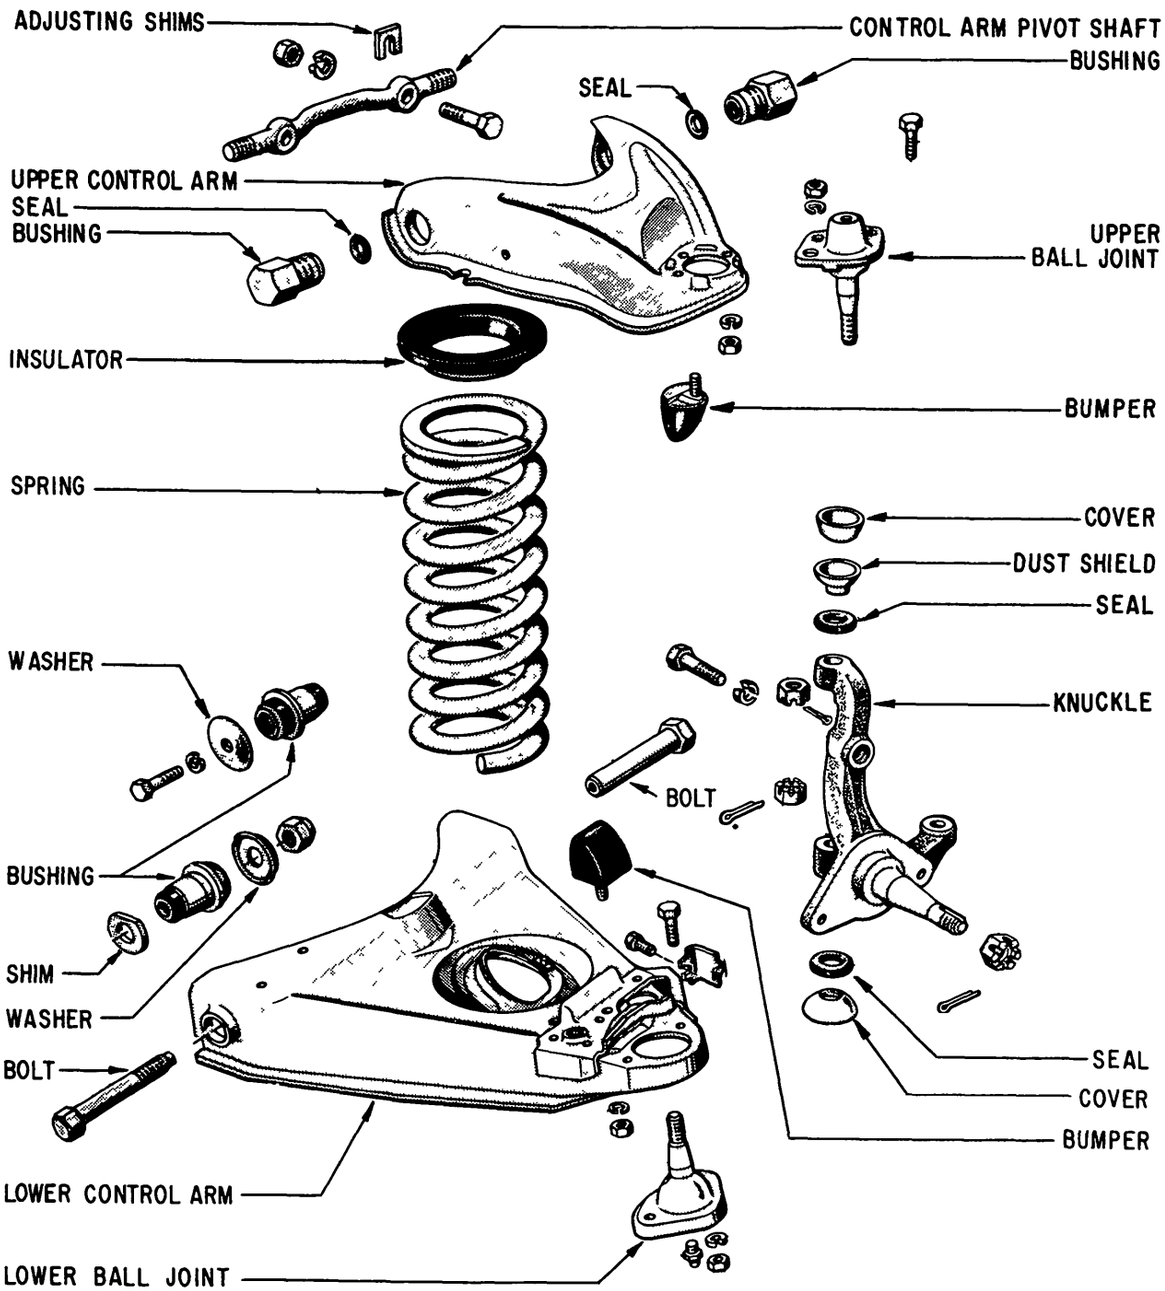
control arms to inner pivot shaft on all models. Upper control arms on 1957 Ford and Mercury, 1958-60 Thunderbird, and early 1958 Edsel are connected to inner pivot shafts by rubber type bushings. All other models have upper control arms connected to inner pivot shaft by threaded steel bushings. *NOTE - On cars with threaded steel bushings, threads in upper control arm pivot bushing holes are cut by steel bushing when bushing is installed.* On 1959-60 Mercury models, the upper control arm inner pivot shaft is mounted directly on top of frame member (not on brackets) and front wheel adjustments are accomplished by moving pivot shaft mounting bolts in elongated holes in frame member (shims not used for camber and caster adjustment).

ADJUSTMENT

CHECKING & ADJUSTING: Before adjusting front end alignment, inflate tires to correct pressure, then raise front of car and check front suspension ball joints for looseness, wear or damage. *NOTE - Lower ball joint is not spring loaded and a slight normal looseness will be found when car is raised and wheel is hanging free. See "Lower Ball Joint Checking" below).* Check steering gear mounting and all linkage for looseness. Adjust front wheel bearings. Check tracking of front and rear wheels.

► *LOWER BALL JOINT CHECKING:* Raise front of car with a jack placed under lower control arm. Adjust front wheel bearing, then, using a dial indicator perpendicular to wheel, measure the in and out travel of wheel (Dial indicator should be clamped to front suspension lower control arm with indicator button contacting edge of the wheel rim). The total travel from extreme inboard to outboard position should be less than .125" (1/8"). Replace ball joint if in excess of this specification.

Caster Specifications



Model	Caster
Ford (1957)	Pos. ½° to Pos. 1½°
Ford (1958-59 Exc. T-Bird)	0° to Pos. 1°
Ford (1960)	ℂ Pos. ¾° to Pos. 1¼°
Thunderbird (1958-60)	Pos. ½° to Pos. 1½°
Mercury (1957-60)	0° to Neg. 1½°
Edsel (1958) ②	0° to Neg. 1½°
Edsel (1959-60)	0° to Pos. 1°

℃ - Supersedes previous specifications of Neg. ½° to Pos. ½°.
② - Corsair & Citation. Pos. ½° to Pos. 1½° (Ranger, Pacer & Station Wagon).

Camber Specifications

Model	Camber
Ford (1957-59)	Pos. ½° to Pos. 1½°
Ford (1960)	ℂ Pos. ½° to Pos. 1°
Thunderbird (1958-60)	Pos. ½° to Pos. 1½°
Mercury (1957-60)	0° to Pos. ¾°
Edsel (1958) ②	0° to Pos. 1½°
Edsel (1959-60)	Pos. ½° to Pos. 1½°

℃ - Supersedes previous specifications of Pos. ½° to Pos. 1½°.
② - Corsair & Citation. Pos. ½° to Pos. 1½° (Ranger, Pacer & Station Wagon).

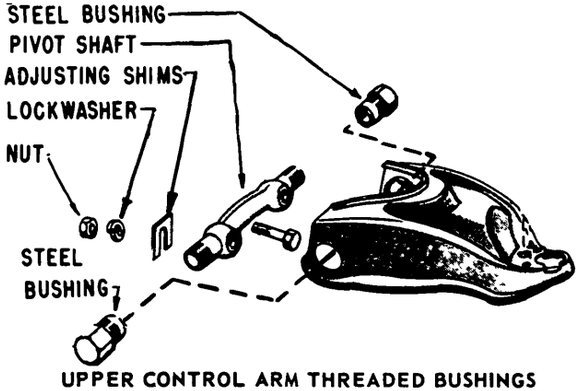
1960 FRONT SUSPENSION ASSEMBLY (TYPICAL)

►*NOTE:* Maximum camber variation between wheels must be less than ½° with ¼° preferred. *See "Shimming Procedur " below.*

T -In: *Se "Toe-In Specification Tabl " below.* To adjust, place front wheels in straight ahead position and

CONTINUED ON NEXT PAGE

1957-60 EDSEL, FORD, MERCURY (C ntinu d)



loosen two clamp bolts at each spindle connecting rod sleeve. If steering wheel spokes are in their normal position, lengthen or shorten both rods equally to obtain correct toe-in. If steering wheel spokes are not in their correct position, make necessary rod adjustments to obtain correct toe-in and steering wheel spoke alignment. *NOTE* - On left hand sleeve turn sleeve **downward to incr as l ngth.** On right hand sleeve turn **upward to increas l ngth.**

Toe-In Sp cifications

Mod l	Toe-In
Ford (1957-59)	1/16-1/8"
Ford (1960)	①1/8-1/4"

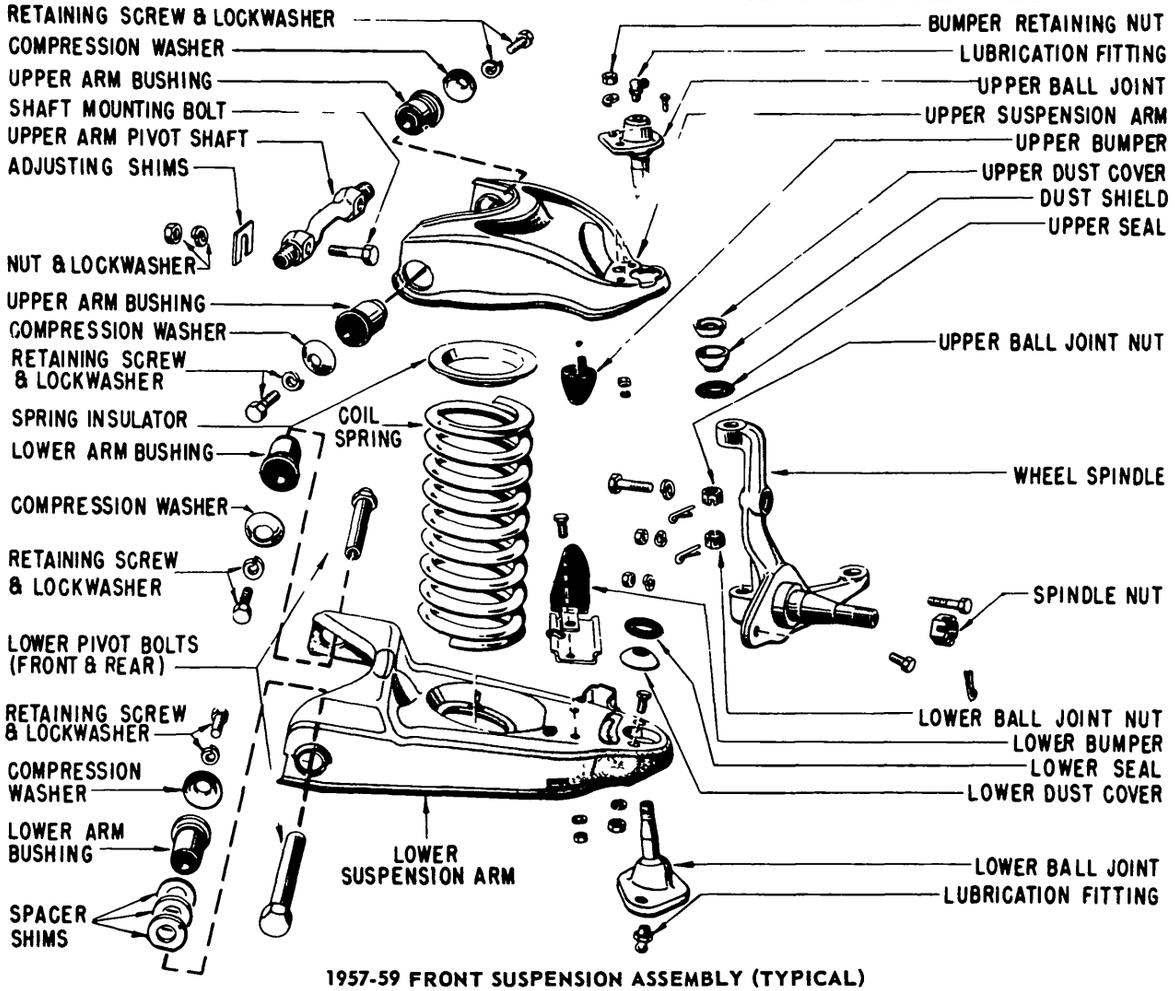
Mercury (1957)	②3/16-5/16"
Mercury (1958)	3/16-5/16"
Mercury (1959-60)	1/16-3/16"
Edsel (1958)③	1/16-3/16"
Edsel (1959-60)	1/16-1/8"

① - Supersedes previous specification of 1/8-5/32".
② - Supersedes previous specification of 1/16-3/16".
③ - Corsair & Citation. 1/32-1/8" (Ranger, Pacer & Sta. Wgn).

T e-Out on Turns: F rd (1957-60) - With **outer** wheel turned 20°, **inner** wheel should be 24¼°.
Thunderbird (1958) - With **inner** wheel turned 20°, **outer** wheel should be 17°7'.
Thund rbird (1959) - With **uter** wheel turned 20°, **inner** wheel should be 24¼°.
Thunderbird (1960) - With **inn r** wheel turned 20°, **outer** wheel should be 17 1/8°.
M rcury (1957-58) - With **inner** wheel turned 20°, **outer** wheel should be 17°6' (Manual Steering); 17°20' (Power Steering).
M rcury (1959-60) - With **inn r** wheel turned 20°, **outer** wheel should be 17°30' (Manual Steering); 17°18' (Power Steering).
Eds l (1958) - With **ut r** wheel turned 20°, **inner** wheel should be 24¾° (Corsair & Citation); 23½° (Ranger, Pacer & Station Wagon).
Eds l (1959-60) - With **outer** wheel turned 20°, **inner** wheel should be 24½°.

UPPER CONTROL ARM THREADED BUSHINGS



CAMBER & CASTER SHIMMING PROCEDURE (EXC. 1959-60 MERCURY): Caster & Camber adjustments are made by adding or removing shims between upper control arm mounting shaft and frame mounting bracket. To change caster, remove or add shims at one of the mounting bolts. The removal of shims at the front bolt or installation of shims at the rear bolt will cause ball joint on upper control arm to move forward. Reversing this procedure will cause joint to move to rear. A 1/16" change of shim thickness at either bolt will change caster angle ½° *(NOTE - The difference between shim stack thicknesses at the two bolts should not exceed 1/8" and the maximum thickness of shim stack at each bolt must not exceed 9/16").* To adjust camber, remove or install equal shim thicknesses at both bolts. Removal of shims at both bolts will move upper ball joint inward, and installation of shims will move upper ball joint outward. A 1/16" change of shim thickness at both bolts will change camber angle ¼°. Shims are available in 1/32" & 1/8" thicknesses. Tighten control arm shaft mounting nuts to 65-90 ft. lbs.

CAMBER & CASTER ADJUSTMENT (1959-60 MERCURY): *NOTE - On early 1959 models with ¼" holes in frame bracket, insert ¼" x 1½" x 20 bolts through holes in bracket. On later 1959 & 1960 models, insert 5/16" x 1½" x 18 bolts through holes in bracket, then install nuts on bolts (between frame bracket and pivot shaft - see illustration).* With bolts installed in bracket, loosen both bolts securing pivot shaft to frame and move shaft by threading bolt in or out as required. See illustration for number of turns of bolts to change camber and caster. When adjustments are correct, tighten pivot shaft bolts to 100-110 ft. lbs., and remove adjusting bolts.

REMOVAL & INSTALLATION

SHOCK ABSORBER REPLACEMENT: Removal - Raise car and place stands under both lower control arms,

CONTINUED ON NEXT PAGE

1957-59 FRONT SUSPENSION ASSEMBLY (TYPICAL)

1957-60 EDSEL, FORD, MERCURY (Con.inued)

making sure that shock absorbers are accessible for servicing Disconnect shock absorber from lower control arm and mounting bracket on frame Free lower stud and bushing from arm by removing one mounting bolt and loosening the other. Remove bushings and washers.

Shock Absorber Lower Bushing Replacement - Remove bushing, using Tool T57P-18201-A1 & A5, and pressing it out of shock absorber with an arbor press. To reinstall bushing, apply a vegetable soap solution to bushing and press it into shock absorber, using Tool T57P-18201-A1, A4, & A5. *NOTE* - One quick drive of the press ram should be used to position bushing

Installation: Place bushings and washers on studs in their correct order. Extend shock absorber and install it inside coil spring with upper stud inserted through hole in mounting bracket. Install and tighten lower bolts to 12-15 ft. lbs Install upper bushing and washer on upper stud and tighten nut to 25-29 ft lbs. Install and tighten locknut.

COIL SPRING REPLACEMENT: *See "Lower Control Arm" below.*

① - Use two or four Shims, Part No. MB-5355-B and two Locators, Part No. MG-55328 also.

UPPER CONTROL ARM: R moval - Raise car and place a stand under lower control arm. Remove wheel and tire and remove cotter pin from nut on upper ball joint stud, tnen loosen nut one or two turns (do not remove nut at this time). Place a box wrench over lower end of ball joint remover, Tool T57P-3006A (Ford), then install the tool between upper and lower ball joints, making sure that tool seats firmly against ends of both studs and not against stud nuts. Turn wrench until tool places studs under tension, then tap spindle near upper stud with a hammer to loosen stud in spindle (do not loosen stud in spindle with tool pressure only). If both arms are being removed, loosen lower stud in same manner as upper stud. Remove nut from upper stud and remove stud from spindle. Support spindle to prevent damage to brake hose. Remove nuts from retaining bolts on upper arm inner shaft (*CAUTION - These bolts are pressed into inner shaft and should not be turned when removing the nuts).* Remove upper control arm from mounting bracket (*CAUTION* -Measure and note thickness of shim pack at each inner shaft bolt).

Inspection: Inspect upper arm and inner shaft for cracks, bends, or other damage. Check condition of bushings, rubber seal on ball joint stud, and rubber bumper on arm. Replace as necessary. Install nut on ball joint stud, then turn stud in ball joint with a torque wrench. If turning effort is not within 25-40 inch pounds, replace the ball joint.

Upper Arm Bushing & Inner Shaft Replacement (All 1957 Models, Early 1958 Edsel, 1958-60 Thunderbird - With "Rubber-Type" Bushings) -With upper control arm assembly removed from car, remove bolts and washers from ends of inner pivot shaft. Use Bushing Remover, Tool T54P-3044-A10 and T54P-3044-A6 at front bushing and press bushing out of arm with an arbor press. Remove inner shaft from rear bushing, then press rear bushing out of arm with Tool T54P-3044-A5 and T54P-3044-A6. Use Tool T54P-4044-A6 and T54P-3044-A9 to press rear bushing into control arm (flange of bushing at outside of arm). Insert end of pivot shaft in rear bushing and press front bushing into arm with Tool T54P-3-44-A. Press all bushings into arm until shoulder ribs of bushings bottom on control arm. *CAUTION - Do not press bushings beyond edge of shoulder ribs or raised section of outer sleeve.*

Upper Arm Bushing & Inner Shaft Replacement (1958-60 Ford & Mercury, Late 1958-60 Edsel - With "Steel-Type" Bushings) - With upper control arm removed from car, hold shaft in a vise and turn bushing off shaft and out of control arm. Install a new "0" ring seal in each bushing, then coat inside of each bushing with a small amount of multi-purpose lubricant (coat outer threads also). *CAUTION - An excessive amount of lubricant inside bushing will force "0" ring seal out of place when bushing installed.* Insert inner shaft in upper control arm, making sure that "bow" in shaft is facing upward (except 1959-60 Mercury); toward center of car (1959-60 Mercury), then install Tool T58P-3044 (Ford); Tool 3082-A (Mercury). *NOTE - See "1959-60 Mercury Upper Susp nsion Arm Spacer Tool R work" above.*

CONTINUED ON NEXT PAGE

1957-60 EDSEL, FORD, MERCURY (C ntinu d)

With tool inserted between arms of upper control arm to properly locate arms the correct distance apart, place tool in a vise and thread bushing on each end of shaft, then turn bushings in until hex heads bottom on upper arm. *NOTE - New upper arms are not threaded. Bushings are self-tapping type.* Tighten bushings to 160-190 ft. lbs. Remove assembly from vise and remove tools, then check to see that shaft rotates with moderate effort. If shaft binds, check for misalignment.

►*1959-60 MERCURY UPPER CONTROL ARM & INNER PIVOT SHAFT REMOVAL & INSTALLATION NOTE:* Before removal of upper control arm, install bolts as described under "Camber & Caster Adjustment (Mercury) Note" above. This will hold wheel alignment procedures to a minimum after replacement of upper control arm.

Upper Ball Joint Replacement - *(NOTE* - The ball joint cannot be repaired and must be replaced if damaged). If ball joint is riveted to arm, drill a 1/8" pilot hole completely through each rivet, then drill off the rivet head through pilot hole with a 3/8" drill. Drive rivets out of holes. Remove burrs from hole edges and install new joint on arm, using only the specified bolts, nuts, and washers (furnished in Ball Joint Repair Kit). *CAUTION - Do not attempt to rivet new ball joint to arm.* Tighten nut on suspension arm bumper to 20-35 ft. lbs. and other ball joint retaining nuts and bolts to 28-45 ft. lbs.

Installation: Position upper arm on frame mounting bracket, then install but do not tighten the nuts on inner shaft retaining bolts *(NOTE - "Keystone" type lockwashers must be used on these bolts).* Install adjusting shims on both bolts between inner shaft and mounting bracket (Install the same thickness of shims that were removed from both ends during disassembly). Tighten nuts on both bolts to 65-90 ft. lbs. Position upper ball joint stud in top of wheel spindle then install stud nut and tighten to 80 ft. lbs. Continue to tighten until cotter pin hole and slots line up. Install cotter pin. Install wheel and tire and remove stand from under lower control arm. Tighten bolts on ends of inner shaft to 40-46 ft. lbs. Lubricate upper ball joint (do not lubricate upper arm bushings). Check and adjust front end alignment.

LOWER CONTROL ARM: Removal - Raise car and place stands under frame side members just back of lower arms and under both front wheels. Remove engine splash shields, disconnect stabilizer from lower arms and loosen both outer stabilizer bushing brackets. Remove both inner brackets, then slide one end of stabilizer at a time out of outer bushings. Disconnect lower end of shock absorber and push it up through lower arm. Remove cotter pin from nut on lower end of ball joint stud, then loosen nut two or three turns (do not remove nut from stud at this time). Loosen lower ball joint (procedure is the same as for upper ball joint, see above). Place a jack under lower arm, then remove nut from lower ball joint stud and slowly lower control arm on jack *(CAUTION - On Mercury be careful to prevent coil spring from jumping out of its seat).* Remove coil spring and insulator. Remove lower control arm retaining bolts, sleeve, and shims, and remove arm from car.

Inspection: Inspect lower arm for cracks, bends, or other damage, and replace arm if necessary. Check condition of ball joint and socket, bushings, rubber seal on ball joint stud, and rubber bumper on arm. Replace damaged parts.

Lower Arm Bushing Replacement - *(NOTE - Replace both lower arm bushings if either bushing is worn or damaged).* Using bushing removing tools, T54P-3044-A13 and T57P-3044-A (Ford), press both bushings out of arms with an arbor press. Press new bushings into arms with tools T57P-3044-A and T54P-3044-A7 (Ford). Bushing flanges must be at inner sides of arm.

Lower Ball Joint Replacement - *(NOTE* - The ball joint cannot be repaired and must be replaced if damaged). Replace ball joint assembly in same manner as for the upper ball joint (see above), using parts furnished in Ball Joint Repair Kit. *CAUTION - Do not attempt to rivet new ball joint to arm.* Tighten nut on suspension arm bumper to 20-35 ft. lbs. and other ball joint retainnuts and bolts to 28-45 ft. lbs.

Installation: Position lower arm on frame crossmember and install shims as needed between forward arm and frame member to remove all fore and aft motion of control arm assembly. Install pivot sleeve and retaining bolt in each arm but do not tighten bolts. Tape insulator to top of coil spring, then position insulator and spring between upper spring seat and lower arm *(NOTE - Mercury springs require a special procedure for installation. See "Mercury Spring Note" below).* Raise lower arm with a jack and guide lower ball joint stud into bottom of wheel spindle. Install and tighten nut to 70-80 ft. lbs., then continue to tighten nut until cotter pin hole and slots line up. Install cotter pin. Remove jack from under control arm and tighten arm retaining bolts to 40-46 ft. lbs. (make sure arms are in normal load position when bolts are tightened). Pull shock absorber down through coil spring and lower control arm and secure it in place. Connect stabilizer to both lower arms. Coat parts with vegetable soap solution and slide ends of stabilizer into outer bushings. Install inner bushing brackets and tighten all inner and outer brackets to 12-15 ft. lbs. Install engine splash shields. Lubricate lower ball joint (do not lubricate lower arm bushings). Check and adjust front end alignment.

►*MERCURY SPRING INSTALLATION NOTE:* Due to free height of the coil spring being greater than distance between upper and lower spring seats, it is necessary to compress the springs approximately 4" before installation. Install spring in an arbor press (if possible, use a salvage 1957 Mercury lower control arm as a holding fixture to properly retain angled lower end of spring while it is being compressed). Compress spring approximately 4", then fasten chains on sides of spring coils so spring will have a slight curve. Remove from press and install in car, making sure that end coil is fully seated in lower control arm.

FRONT WHEEL SPINDLE: R m val - Raise car until front wheel clears floor, then place a support under lower control arm. Remove wheel and drum. Remove brake backing plate and support it to prevent damage to brake hose. Remove upper and lower ball joints (see above), and remove spindle.

Installation: Reverse removal procedure and note the following: Install brake backing plate and tighten upper retaining bolts to 62-72 ft. lbs. Tighten lower bolts to 25-29 ft. lbs. Check and adjust front wheel alignment.

STABILIZER: *NOTE - Removal & Installation of stabilizer is different on Ford and M rcury as not d b low:*

Removal (Ford): Raise car and place supports under both front wheels. Remove engine splash shields and disconnect stabilizer from lower control arms. Loosen both stabilizer outer bushing brackets and remove both inner bushing brackets. Slide one end of stabilizer at a time out of outer bushings.

Installation (Ford): Connect stabilizer to both lower arms. Coat parts with vegetable soap solution and slide ends of stabilizer into outer bushings. Install both inner bushing brackets, and tighten all inner and outer brackets to 12-15 ft. lbs. Install engine splash shields.

Removal (Mercury): Remove engine splash pan and front wheel. Remove two stabilizer to frame mounting brackets and slide left rubber mounting insulator along stabilizer bar about three inches toward center of car. Disconnect stabilizer bar from links and remove rubber insulators from eyes of bar. With front suspension in full rebound, remove bar by moving it out to right of car. The right eye at end of stabilizer bar will just pass over right front brake drum. *NOTE* - It may be necessary to spread coils of left spring slightly to allow left end of stabilizer bar to pass through spring during removal.

Installation (Mercury): Reverse removal procedure. Tighten bracket bolts to 12-15 ft. lbs.

1957-60 FORD THUNDERBIRD LINCOLN & CONTINENTAL

Ford Thunderbird (1957)
Lincoln (1957-60)
Continental (1957-60)

►*JACKING & HOISTING: See "Jacking & Hoisting Precautions".*

►*1958-60 LINCOLN & CONTINENTAL LOWER CONTROL ARM BALL JOINT CHECKING NOTE: Ball joint is not spring loaded and will appear to have excessive movement when wheel is shaken. This movement is normal and does not affect operation of joint.*

DESCRIPTION: "Ball-joint" type with direct acting shock absorbers mounted within front coil springs.

ADJUSTMENTS

CHECKING & ADJUSTING: *ADJUSTMENT NOTE - Due to differences in mounting upper control arm shaft and location of caster & caster adjusting shims, Thunderbird models are adjusted differently than Lincoln & Continental models. See Adjustment data following:*

Tire Inflation: Lincoln (1957-60) - 24 lbs., front & rear. **Continental (1957)** - 26 lbs., front; 24 lbs., rear. **Continental (1958-60)** - 24 lbs., front & rear. **Thunderbird (1957)** - 22 lbs., front & rear.

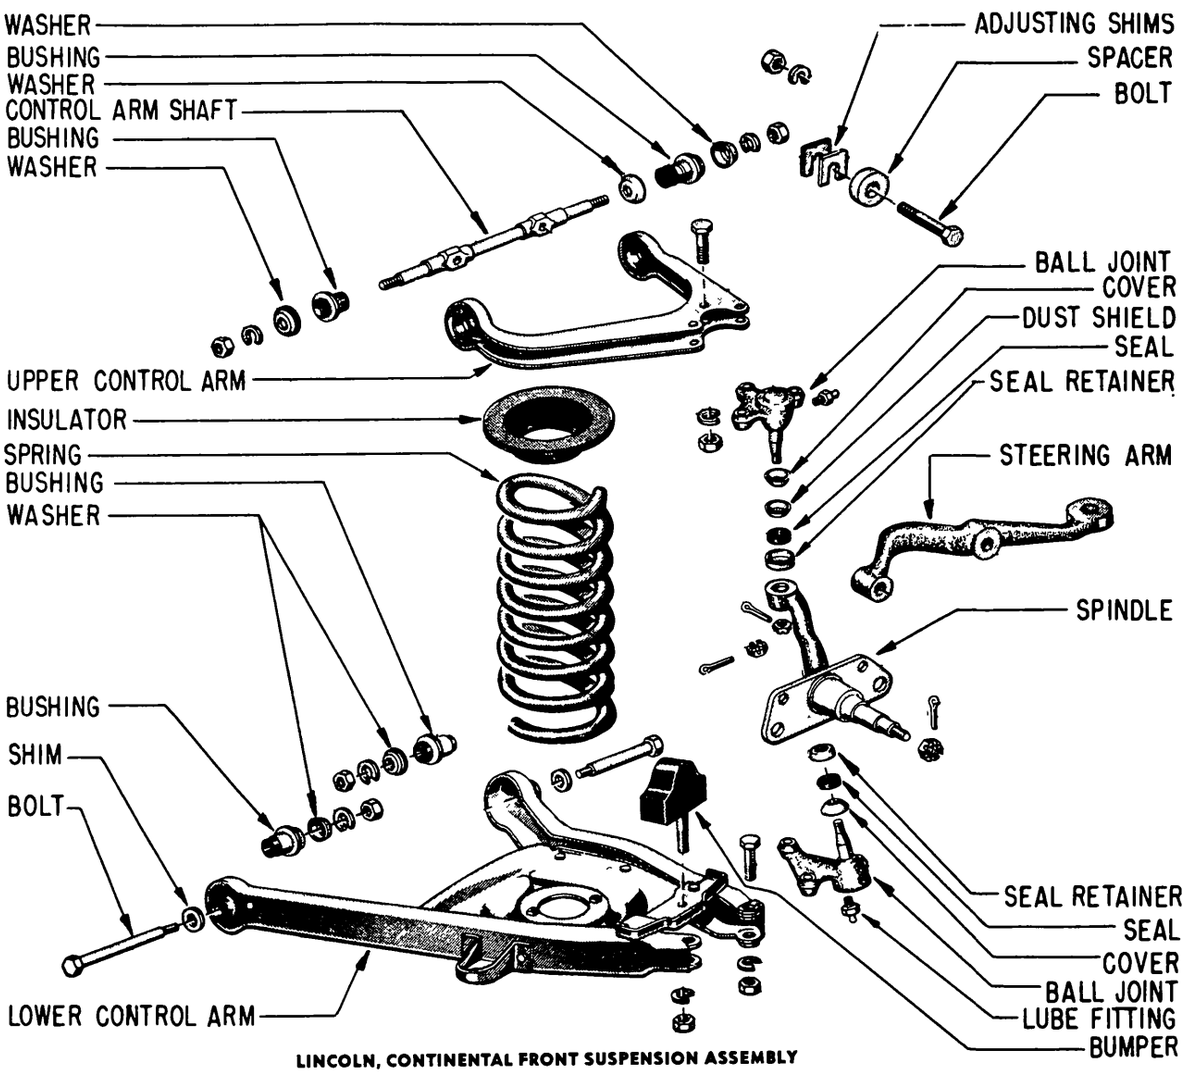
Caster: Lincoln (1957-60) - 0° to Neg. 1½°. **Continental (1957)** - Pos. 1°±¼°. **Continental (1958-60)** - 0° to 1½°. **Thunderbird (1957)** - Pos. ½° to Pos. 1½°. Caster should not vary more than ½° from side to side. *See "Shimming Procedure" below.*

Camber: Lincoln (1958-60) - 0° to Pos. ¾°. **Continental (1957)** - Pos. ¾°±¼°. **Continental (1958-60)** - 0° to Pos. ¾°. **Thunderbird (1957)** - Pos. ½° to Pos. 1½° Camber should not vary more than ¼° from side to side. *See "Shimming Procedure" below.*

Toe-In: Adjust to following specifications.

Toe-In Specifications

Model	Toe-In
Lincoln (1957-59)	1/8-3/16"
Lincoln (1960)	1/16-3/16"
Continental (1957)	3/32-5/32"
Continental (1958-59)	1/8-3/16"
Continental (1960)	1/16-3/16"
Thunderbird (1957)	1/16-1/8"



Toe-Out In Turns: Wheel angles should be as follows. No adjustment provided.

Wheel Angle Specifications

Model	Inner Wheel	Outer Wheel
Lincoln (1957)	36°	26°
Lincoln & Cont. (1958)	27°45'	28°
Lincoln & Cont. (1959-60)	37°45'	27°26'
Thunderbird (1957)	25°	20°

Shimming Procedure: Caster and camber adjustments are made by adding or removing shims between upper control arm mounting shaft and frame mounting bracket. To change caster, remove or add shims at one of the mounting bolts. *(NOTE - On Thunderbird, the adjusting shims are located between inner side of mounting shaft and frame bracket. On Lincoln & Continental these shims are located between outer side of mounting shaft and frame bracket).* On Thunderbird, to **increase positive caster,** add shim at **front** bolt or remove shims at **rear** bolt. On Lincoln & Continental, to **increase positive caster,** add shim at **rear** bolt or remove shim at **front** bolt. To change camber, remove or install equal shim thicknesses at both front and rear mounting bolts. On Thunderbird, for positive camber increase, add shims equally at both bolts. On Lincoln & Continental, remove shims equally at both bolts. A 1/16" shim change at either bolt will change caster ½°. A 1/16" shim change at both bolts will change camber ¼°. Tighten control arm mounting shaft bolts to 65-90 ft. lbs. (Thunderbird), 75-90 ft. lbs. (Lincoln & Continental).

►*ADJUSTING SHIM THICKNESS NOTE:* Difference in thickness of shim pack at front and rear bolts must not exceed 1/8". Total shim pack thickness at each bolt must not exceed 9/16".

LINCOLN, CONTINENTAL FRONT SUSPENSION ASSEMBLY

1957-58 Tightening Specifications (Lincoln & Continental)

	Ft. Lbs.
Lower Control Arm to Front Underbody	55-75
Lower Ball Joint to Wheel Spindle	70-90
Lower Control Arm Bumper to Arm	22-24
Shock Absorber to Lower Arm	10-13
Shock Absorber Top Attaching Nut	60-75
Stabilizer Assembly & Bracket	22-24
Upper Ball Joint to Wheel Spindle	60-80
Upper Control Arm Inner Shaft to Shaft Bushings	55-75
Upper Control Arm Shaft to Underbody	70-80

Upper Control Arm Inner Shaft to Bushings	40-46
Upper Ball Joint to Wheel Spindle	80
Lower Ball Joint to Wheel Spindle	70-80
Lower Control Arm Bumper to Arm	20-35
Lower Control Arm to Inner Brackets	40-46
Stabilizer Assembly Brackets	12-15

RIDING HEIGHT: 1957 Lincoln - 4.18-4.65" measured vertically from underside of frame to top of lower control arm adjacent to bumper.

1958 Lincoln & Continental - With car on a level surface and at curb weight (no passengers, luggage compartment unloaded, and gas tank full) bounce car several times and allow it to settle to normal height. Measure distance from level surface on float to center of front inner pivot of lower control arm, then measure distance from level surface of floor to bottom of lower ball joint on same side of car. The differences between these measurement should be between 1 5/32" and 1 21/32" (1958); 1½ and 2" (1959); 2" and 2¾" (1960). Measure opposite side of car in same manner. Difference between sides should not exceed ½".

① - Without Air Conditioning. ② - With Air Conditioning.
③ - Use Shim, Part No. PB8L-5355-A as necessary.
④ - Same as Lincoln models.

REMOVAL & INSTALLATION

►*SHOCK ABSORBER APPLICATION NOTE: See "Shock Absorbers" on Car Model pages.*

COIL SPRING REPLACEMENT: *See "Lower Control Arm" below.*

LOWER CONTROL ARM: Removal - Raise front of car and place stand under each side of frame or underbody to rear of lower control arm. *NOTE - See "Jacking & Hoisting Precautions".* Remove wheel and brake drum as an assembly, then remove backing plate assembly from spindle and attach to frame with a wire. Remove shock absorber and disconnect stabilizer bar from lower arm. Loosen lower ball joint-to-wheel spindle stud nut two turns and loosen ball joint *(see "Ball Joint Removal" below).* Place a jack under lower control arm and raise arm until rebound bumper on upper arm is clear of frame or underbody. Remove nut from lower ball joint stud and lift spindle up and off stud. Lower jack until spring tension is relieved and spring can be removed. Remove spring, insulator and retainer ring note (location of these parts to insure correct reassembly). To remove lower control arm, take out bolts attaching arm to frame or underbody. Inspect bushings on inner end of each member and replace if necessary.

Bushing Replacement - Press bushings from control arms using an arbor press and the following tools: 3069, 3069-F, & 3069-J (Lincoln & Continental), T54P-3044-A13, & T54P-3044-A6 (Thunderbird). Install bushings in control arm with tools 3069 & 3069-A (Lincoln & Continental), T54P-3044-A6 & T54P-3044-A7 (Thunderbird). Press bushings into arm until shoulder ribs of bushings bottom on control arm. *(CAUTION* - Do not attempt to press bushings beyond edge of shoulder ribs or raised section of outer sleeve. Under no circumstances should only one bushing be replaced).

Installation: Install lower arm rear leg to frame or underbody crossmember and tighten attaching nut to proper specifications *(see "Tightening Specifications" above).* Add enough shims between forward arm and crossmember to fill existing space and tighten nut finger tight. *NOTE - Shim pack at this point should not exceed ½".* Loosen nut on rear bolt to a finger tight position. With arm in curb load position (approximately horizontal, with outer end slightly lower than inner), tighten nuts to specifications. Place coil spring and upper rubber insulator in position, then place a jack under lower control arm and compress the spring, making sure that both upper and lower ends of spring are properly seated. Guide spindle boss over ball joint stud, then install stud nut and tighten to specifications. Continue to tighten nut until cotter pin hole is lined up with slot in locknut. Remove jack from under control arm and install shock absorber. Secure stabilizer to lower control arm, then install backing plate, wheel, and drum. Adjust front end alignment.

BALL JOINT (UPPER & LOWER): Removal - Ball joints are furnished as assemblies except for seals and related parts assembled on ball joint stud. Raise front of car with a jack placed under lower control arm, then place a support under frame side rail to rear of control arm. Remove front wheel and cotter pin in ball joint stud *(NOTE* - If both ball joints are to be removed, free the lower stud first). Loosen stud nut approximately two turns and install Tool 3006-A with the screw end resting against lower stud nut. Turn screw of tool and apply sufficient pressure to place ball joint under tension. Strike the spindle sharply at a point opposite the stud bore to pop it loose. Increase tension and strike again if necessary *(CAUTION - Spindle or tool may be damaged if pressure only is used to free stud).* Repeat this procedure with other stud if necessary. Remove ball joint from control arm by removing the attaching screws. Remove retainer, seal, and covers from stud. Inspect parts for damage and replace if necessary. If new rubber seals are being installed, make sure they are pushed down into retainer cup before cup is installed. Reassemble all seal parts in original position.

►*CAUTION: Do not wash ball joint assemblies with solvent which may remove lubricant.*

Installation: Reverse removal procedures and tighten all bolts and nuts to proper specifications. *See "Tightening Specifications" above.*

UPPER CONTROL ARM: Removal - Place jack under lower control arm near ball joint mounting and raise lower arm until some of the tension has been removed from upper control arm. Remove wheel and tire assembly. Wire spindle to frame to avoid damage to brake hose.

CONTINUED ON NEXT PAGE

1957-60 FORD THUNDERBIRD LINCOLN & CONTINENTAL (C nt.)

Remove cotter pin from ball joint stud and loosen nut approximately two turns. Loosen ball joint stud *(see "Ball Joint R moval" abov)*, then remove ball joint nut. Remove bolts securing inner shaft to frame *(NOTE* - Check and record amount of shims removed from between control arm mounting shaft and frame). Remove upper control arm.

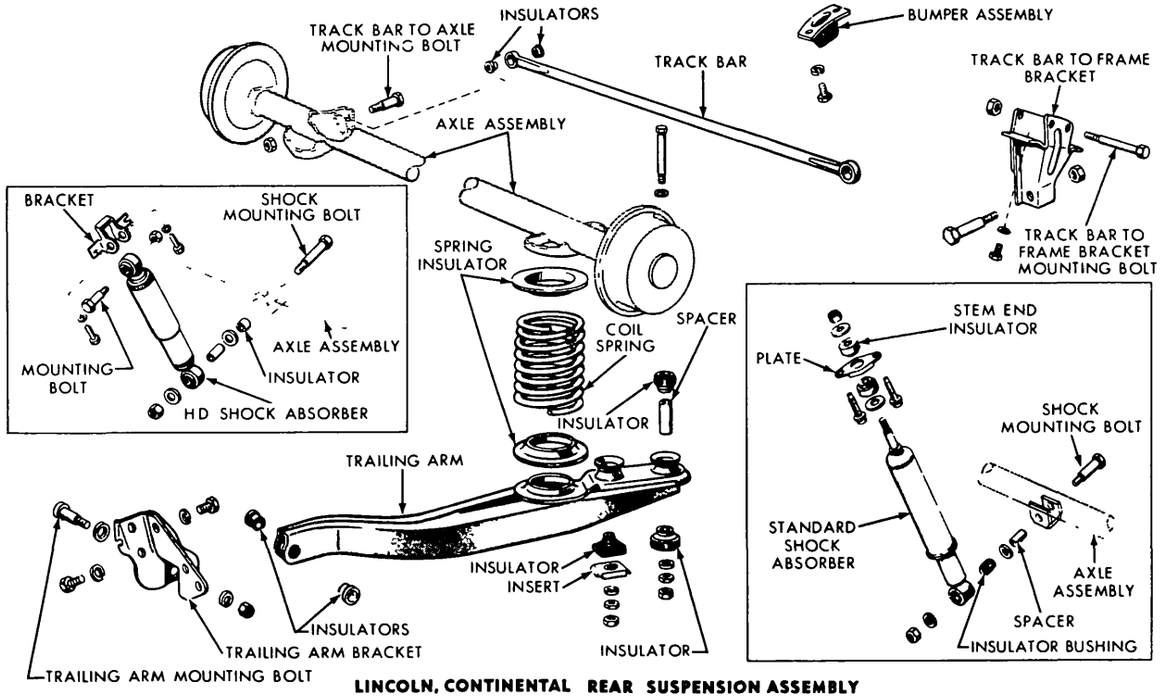
Bushing R plac m nt (Linc ln & Continental) - Install Tool 3044-B on inner shaft and place Tool 3069 over bushing. Press bushing from arm. Remove mounting shaft and steel washer. To remove the opposite (double shoulder bushing), on rear upper arm, insert Tool 3069-F into flange of arm, then place Tool 3069 over bushing and into recess of Tool 3069-F. Center bushing over Tool 3069-G and press out *(NOTE* - Tool 3069-G will shear rubber until steel shell is contacted). To install double shouldered bushing in rear of upper arm, lubricate rubber portion of bushing for easier installation. Position Tool 3069 on inner side of rear arm. Install bushing in hole (entering it from outer side of arm), and position Tool 3068 over bushing. Press bushing into arm until shoulder stop is reached. Install long machined end of inner mounting shaft, with washer, into bushing. Install bushing in front arm, positioning it over end of shaft and pressing it into place with Tool 3068. With both bushings in place, install nut and washer on each end of shaft and tighten finger tight. Position shaft in suspension arm so that holes are parallel with shaft and tighten nuts to specifications. S *"Tightening Specifications" above. CAUTION - Under no conditions should only one bushing be installed.*

Bushing Replacement (Thunderbird) - Install bushing remover Tools T54P-3044-A6 & T54P-3044-A5 in arbor press and press rear bushing out of arm. Install rear bushing with Tools T54P-3044-A6 & T54P-3044-A9. Bushing flange should be at outer side of arm. Insert end of mounting shaft in rear bushing, then press new front bushing into arm using Tool T54P-3044-A8. Install bolts and washers on both ends of shaft, but do not tighten bolts until upper arm is installed on the mounting bracket.

1958-59 LINCOLN & CONTINENTAL REAR SUSPENSION

Linc ln (1958-59)
C ntinental (1958-59)

►*JACKING & HOISTING See "Jacking & Hoisting Precauti ns".*



►*1958 SUSPENSION ARM BUSHING & PIN ASSEMBLY PRODUCTION CHANGE & SERVICE REPLACEMENT*

NOTE: Larger suspension arm pin assemblies, Part No LF-5886-D (7/8" diameter), and bushings, Part No. LF-55272-A are used in later production cars. If suspension arms are removed or if noise occurs in this area on earlier cars, install later type pin and bushing assen.blies

►*1959 TRAILING ARM MOUNTING BOLT TIGHTENING CAUTION (T prev nt xcessive wear and noise):* Trailing arm axle mounting bolts (with double nuts) should be tightened to 50-60 ft. lbs. and the trailing arm-to-hanger bolts should be tightened to 55-65 ft. lbs. every 4,000 miles. If loss of torque is noted, insulators and spacers should be inspected for wear and replaced as necessary.

DESCRIPTION: Coil spring rear suspension system consists of two suspension arms connected at the rear to rear axle housing and at the front to brackets attached to car underbody. Coil springs are located between suspension arms at center and spring seat in underbody A stabilizer bar connected to underbody on left side and to rear axle housing on right side control lateral movement of rear axle housing

COIL SPRINGS: R moval - Raise car on a hoist or jack and place a jack stand under box section of underbody directly opposite each end of fuel tank. Using a floor jack, raise rear axle housing and disconnect lower end of shock absorber from rear axle housing Remove locknut, nut, and bolts securing suspension arms to rear axle housing, then lower rear axle housing just enough to free coil springs. *NOTE* - If a replacement of a spring is necessary, both should be replaced.

LINCOLN, CONTINENTAL REAR SUSPENSION ASSEMBLY

Installation: Reverse removal procedure

Model	Rear Spring Application	Part No.
All (Exc Following)		LF-5560-C
Convertible		LF-5560-D
Heavy Duty & Air Cond		LF-5560-D

REAR SUSPENSION ARMS: Remove coil springs (see above), then disconnect parking brake cable and hydraulic brake line from suspension arms Remove nut and bolt securing arm to underbody bracket and withdraw arm

Installation: Reverse removal procedure.

1958 FORD & MERCURY REAR SUSPENSION (AIR SUSPENSION CARS)

F rd (Except Thunderbird) (1958)
M rcury (1958)

DESCRIPTION: Rear axle is attached to car frame by two trailing arms which allow vertical and roll movement. A track bar located to rear of axle assembly is attached to frame side rail on one side and to rear axle housing on the other to control lateral movement of the axle Shock absorbers are mounted at the top to brackets located at rear of frame crossmember, and at the bottom to brackets located on front of rear axle housing.

REAR SUSPENSION ARM: Removal Loosen air line connection at top of air spring assembly and allow pressure to escape. *(CAUTION - Do not remove fitting while spring is under pressure).* Remove air spring lower mounting nut, then remove four nuts securing rear of suspension arm to suspension arm mounting bracket. Remove locknut from forward end of suspension arm and remove metal washer. Remove suspension arm assembly by pulling toward rear and out of rubber bushing. Remove remaining rubber bushing and washer from arm assembly, then remove rubber bushing from frame bracket.

Installation: Position metal washer and bushing on suspension arm and position arm in frame bracket. Install second bushing on arm and install outer washer and locknut. Install four locknuts attaching suspension arm to arm mounting. Install rear spring lower mounting nut and connect air line fitting to top of air spring.

SUSPENSION ARM MOUNTING BRACKET: Removal - Loosen, but do not disconnect, air line at top of spring, and allow air pressure to escape. After pressure has escaped, disconnect the air line. Remove four locknuts holding suspension arm on mounting bracket *(NOTE* - Bolts cannot be removed until bracket is removed) Support rear axle assembly with jack stands, then remove two bolts and nuts securing bracket on rear axle assembly, and remove bracket Remove retaining bolts from bracket.

Installation: Position suspension arm mounting bolts in bracket, then position bracket in mounting bracket on rear axle assembly and install retaining nuts and bolts (heads of bolts toward centerline of car). Position rear suspension arm on bracket and install four locknuts and tighten to 65-75 ft. lbs. Tighten bracket mounting nuts to 80-100 ft. lbs. Connect air line to spring.

TRACK BAR: Removal (Ford) - Remove locknut from end of track bar on right side and remove washer, rubber bushing and the second washer. Remove bolts securing left side mounting bracket to frame, then pull left mounting bracket and bar as an assembly, out of right mounting bracket.

R moval (Mercury): On right side of car, remove nut on track bar bracket and pull track bar from bracket. Remove rubber bushings and washers. Remove nut from left end of track bar and pull bar from bracket, then remove rubber bushings and washers.

Installati n (Ford & M rcury): Reverse removal procedure.

1958 FORD THUNDERBIRD REAR SUSPENSION

F rd Thund rbird (1958)

►*JACKING & HOISTING: See "Jacking & Hoisting".*

DESCRIPTION: Rear axle is attached to car underbody by two suspension arms at each side. Lower suspension arms are attached to lower side of rear axle housing at the rear and to a bracket in car body at the front. Upper suspension arms are attached to top of rear axle housing adjacent to brake backing plate, and to car body. A track bar connected to a bracket on left side of car body and to a bracket on right end of rear axle housing control lateral movement of rear axle assembly. Shock absorbers are mounted between a bracket on rear side of rear axle housing and a bracket on car body.

REMOVAL & INSTALLATION

TRACK BAR: Removal - Raise car and remove nut and bolt from each end of track bar, and remove track bar. If bushings are to be replaced, remove old bushings.

Installation: To install new bushings, apply RuGlyde or a similar lubricant and press bushings into track bar, using Tool T58P-55551-A-1 and an arbor press. Support end of track bar on Tool T58P-55551-A-3 while pressing bushings into place. Position track bar in mounting brackets and tighten mounting bolts to 80-100 ft. lbs.

LOWER SUSPENSION ARM: Removal - Raise car and install supports under rear crossmember *(NOTE - If twin post hoist is used there must be at least 4¾" clearance between hoist fork and suspension arm horizontal mounting bolt).* Remove rear wheels and disconnect drive line at rear universal joint. Disconnect both shock absorber lower mounting brackets and disconnect brake fluid line bracket. Disconnect track bar at axle mounting bracket, then disconnect both upper suspension arms at front, and lower rear axle assembly, and remove the spring. Remove nut from insulator retaining bolt, and remove the insulator washer, lower insulator spacer and bolt. Remove horizontal bushing retaining bolt, then remove lower arm front retaining bolt, and remove suspension arm. Remove four bolts attaching support mounting to suspension arm. Using Tool T58P-55551-A-1 and Tool T58P-55551-A-3, press out bushings from support and from front of arm.

Installation: Apply RuGlyde or a similar lubricant to bushings, then press bushings into support and front of arm, using an arbor press and the same tools used for bushing removal (see above). Install support on arm and tighten mounting nuts to 65-75 ft. lbs. Install front end of arm in mounting bracket then install, but do not tighten, mounting nut and bolt. Position rear end of arm so the support bolt coil spring and upper insulator can be positioned Install, but do not tighten, the nut. Position insulator retaining bolt, spacer, lower insulator, and washer. Install, but do not tighten, the nut Raise axle assembly so upper arms can be connected to body, then partially tighten attaching bolts. Connect track bar, leaving bolt partially loose. Remove safety stands so axle will be positioned at normal ride height and tighten all nuts and bolts to specifications *(see "Tightening Specifications" below).* Connect shock absorbers and tighten mounting bolts to 12-15 ft. lbs. Connect brake line bracket, then install wheels and connect rear universal joint. Tighten nuts to 15-20 ft. lbs., and lower car to floor

COIL SPRINGS: Removal - Raise and support car *(see* "Lower Suspension Arm" above), then remove rear wheels and disconnect rear universal joint Disconnect both shock absorbers at lower mounting bracket, and disconnect brake fluid line bracket. Disconnect track bar from axle mounting bracket and both upper suspension arms at front end Lower axle assembly and and remove the coil spring (upper insulator may fall out). Remove coil spring insulator from spring pocket.

Installation: Tape coil spring insulator to top of spring and position spring in its pocket and on suspension arm pedestal *(NOTE - Lower end of spring must seat against end of boss on pedestal).* Raise rear axle assembly so it is at normal riding height Connect track bar, and tighten bolt to 80-100 ft. lbs. Connect upper arms and tighten bolts to 80-100 ft lbs Connect shock absorbers and tighten nuts to 12-15 ft lbs., then connect brake line bracket. Install wheels and connect universal joint Tighten nuts to 15-20 ft lbs and lower the car

►*COIL SPRING REPLACEMENT NOTE: Standard spring, Part No. B8S-5560-A, is the only spring available for these models.*

SHOCK ABSORBERS: Removal - Disconnect shock from suspension arm mounting bracket, then remove rear wheel and disconnect shock at body bracket and remove shock Remove bushing and washer from upper stud *(NOTE* - Remove lower bushing only if shock absorber is serviceable and bushing requires replacement, using an arbor press and Tools T57P-18201-A1 & A5)

Installation: If bushing was removed, install a new bushing using Tools T57P-18201-A1, A4 & A5 ·Use RuGlyde on bushing and drive it into place with one quick movement of arbor press Complete installation by reversing removal procedure Tighten upper nut to 15-25 ft lbs , and lower nuts to 12-15 ft. lbs.

Tightening Specifications

	Ft. Lbs.

Rear Suspension Arm Pivot (front)	80-100

1954-55 NASH & RAMBLER FRONT SUSPENSION

Nash (1954-55)
Rambler (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 ALL CARS (EXC RAMBLER) FRONT SUSPENSION CROSSMEMBER INSTALLATION CAUTION:* Reinstallation of the crossmember after removal for service operations requires special attention to proper spacing of the suspension brackets as follows. There should be 19½" between the centers of the front and rear inner crossmember-to-mounting bolt bracket holes to insure maintaining the front wheel alignment.

DESCRIPTION: Independent linked parallelogram type with new type coil spring and shock absorber mounting as follows

Coil Springs—Mounted above upper control arm with lower end piloted in spring seat mounted on knuckle support upper trunnion and upper end piloted on spring seat in frame

Shock Absorber—Upper end mounted on bracket (part of upper control arm pivot bar—Rambler)

►*NOTE Front Suspension Systems are similar, but parts are not interchangeable*

►*CONTROL ARM ASSEMBLY INTERCHANGEABILITY CAUTION* Upper Control Arm and Lower Control Arm assemblies **are interchangeable from right to left on Rambler Series only.** Statesman & Ambassador require different control arms for right and left and for front and rear arms

CHECKING & ADJUSTMENT: Check wheel bearing adjustment steering gear adjustment, tire inflation pressure, wheel and tire balance and runout, then place car on level floor, check as follows

Kingpin Inclination: 8½° (Rambler), 6½° (Nash) Not adjustable.

Camber: Rambler - Pos. ¼° to Pos ¾° (½° preferred). **Nash** - Neg ¼° to Pos ¼° (0° preferred)

►*NOTE Loosen front suspension brace before adjusting Caster and Camber.*

Adjustment - Add or remove "C" washers equally at both studs, as required between lower support arm pivot bar and frame bracket or shoulder of mounting stud Adding washers will **increase** Camber angle Removing washers will **decrease** Camber angle

►*CAUTION* "C" washers of equal thickness must be removed or installed from each end of control arm pivot bar OR CASTER WILL BE CHANGED

Caster: Rambler - Pos ¾° to Pos 1¼° (1° preferred)
Nash - Manual Steering - 0° to Pos ½° (0° preferred)
Power Steering - Pos ½° to 1° (1° preferred)
Adjustment - Add or remove "C" washers between lower control arm pivot bar and frame bracket or mounting stud shoulder To increase Caster, ADD "C" washer at FRONT end of pivot bar To decrease Caster, ADD "C" washer at REAR end of pivot bar.

Toe-In: Rambler - 1/8" to 1/4" (1/4" preferred) **Nash** - 1/16" to 3/16".

Adjustment - Measured at a point 8" above floor with wheels set in straight-ahead position Loosen tie rod adjusting tube clamps and turn adjusting tubes equally in opposite directions

►*NOTE Before tightening tie rod clamp bolts, square up the ball joint studs.*

Toe-Out on Turns: With inner wheel turned as indicated below, outer wheel should be as follows

Car Model	Inner Wheel	Outer Wheel
Rambler (1954)	23°, plus ½°, minus 0°	20°
Rambler (1955)	25°	21½°
Nash (1954 Amb.)	23°, plus ½°, minus 0°	20°
Nash (1954 Stsm.)	23½°, plus ½°, minus 0°	20°
Nash (1955 Amb. V8)	25°	©
Nash (1955 Stsm)	25°	20¾°

© - 20¼° (Exc. V8 Pwr. Strg.), 21¾° (Pwr Strg.).

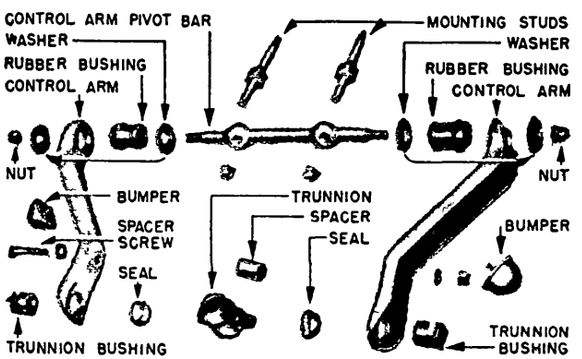
UPPER & LOWER CONTROL ARMS: Control arms are attached to pivot bars by rubber insulated bushings Outer end of control arm is attached to trunnions by threaded bushings except the upper trunnion on Rambler which is attached with a screw and locked in place with a nut and lockwasher

Removal Remove the Harris type rubber bushings by driving them straight out of control arm Do not turn or twist (bushings must be tight press fit)

Installation Rubber bushings can be installed into the control arms by using two inner bearing cones of suitable size (Statesman or Rambler rear axle rear pinion bearing inner cone is right size) as pressing tools Place control arm in arbor press and start bushing into flanged side of control arm Install pivot bar inner washer over bushing and place cups in position (one over washer and the other on the under side of control arm to provide clearance in press) Press bushing into control arm until bushing is ⅛" from arm

Steering Knuckle Pin Installation (Lower) Screw knuckle pin into lower trunnion until there is approximately ⅛" clearance between shoulder on knuckle pin and trunnion

Steering Knuckle Pin Installation (Upper-Nash): Upper control trunnion incorporates needle bearings and is retained on knuckle pin by a castellated nut and pin. A thrust bearing installed on knuckle pin between lower side of upper trunnion and a shoulder on knuckle pin absorbs end thrust of knuckle pin.



Steering Knuckle Pin Installation (Upper-Rambler): On 1954 models, bolt the spring seat to trunnion prior to installation of knuckle pin into trunnion, then proceed as for lower knuckle pin (above) 1955 Models are the same as for Nash (above) *NOTE - On 1955 models, two self-tapping screws must be removed to permit removal of lock pin.*

Front Suspension Tightening Specifications: *NOTE*—It is very important that tightness of front suspension system be maintained The following torque values will insure correct tightness

	Ft Lbs
Pivot Bar Bushing Retaining Nut	50-55
Lower Shock Mounting	90-95
Upper Control Arm Spacer Nut Screw	50-55
Lower Mounting Stud to Sill	75-85
Upper Mounting Stud to Sill	35-45
Upper Pivot Bar to Mounting Stud Nut	75-80
Lower Pivot Bar to Mounting Stud Nut	75-85

COIL SPRING REPLACEMENT *(NOTE*—Two front coil spring compressors used (KMO-735 for Rambler J 5224 for Others) Remove two rebound bumpers from upper control arms and raise front end of car to permit spring to extend to its full rebound position Install upper section of one compressor on highest coil of spring and lower section of other compressor on lowest coil

CONTINUED ON NEXT PAGE

UPPER CONTROL ARM

LOWER CONTROL ARM

NASH & RAMBLER CONTROL ARM ASSEMBLIES

1954-55 NASH & RAMBLER FRONT SUSPENSION (Cont.)

Lower front end of car to partially compress spring with car weight (Maintain support under front end). Install remaining sections of compressors enclosing the five (Rambler), nine (Others) coils. Raise front of car and remove wheel, hub, and drum as an assembly. Tighten compressors evenly until spring can be removed.

►*CAUTION:* Lip of lower spring seat must engage upper end of knuckle pin to prevent spring slipping off pin.

►*SPRING REMOVAL NOTE: To facilitate installation and removal of spring compressor tools, a spring compressor can be made from two Ambassador Series lower spring retainers and a 5/8" bolt 18" long threaded at both ends. Insert bolt through spring and install spring retainers, then draw spring together by turning nuts on bolt.*

Spring Free Height

Rambler, 100" W.B. (Early Type Spring)	18"
Rambler, 100" W.B. (Later Spr., Std. & O.D.)	16 7 8"
Rambler, 100" W.B. (Hydra-Matic)	18"
Rambler, 108" W.B. (Std. & O.D.)	18"

1955-57 HUDSON, NASH, RAMBLER FRONT SUSPENSION

Hudson 1955-57
Nash 1955-57
Rambler 1956-57

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 HUDSON & NASH ECCENTRIC BOLT NUT BOTTOMING ON SHOULDER OF ECCENTRIC BOLT CORRECTION & PARTS PRODUCTION CHANGE:* Eccentric bolt will not tighten sufficiently to prevent eccentric bolt from turning. On early cars install a 5/8" I.D. washer between nut and eccentric washer. At Car Serial V-1511 (Ambassador V8), R-743047 (Ambassador 6 Cyl.); K-635286 (Statesman); Y-1292 (Hornet V8); X-1152 (Hornet 6 Cyl.); W-1200 (Wasp); the counterbore of the eccentric bolt nut has been increased to 3/16".

►*1956 FRONT TIRE RUBBING NOTE:* Inside wheel on right or left turns should be adjusted to a maximum turn angle of 38° (Rambler), 36° (Others) to avoid possibility of damaging front wheel tires as a result of contacting brake hose bracket on tight right or left turns. In addition, it is recommended that rear corner of brake hose bracket be trimmed 1/8" to prevent possible tire damage under abnormal turning conditions such as steep driveways. Effective April 11, 1956, brackets have been reworked in production.

►*LOWER CONTROL ARM THROUGH BOLT TIGHTENING CAUTION:* The lower control arm through bolt which also acts as the front shock absorber lower anchor is a special heat treated bolt that must be properly tightened to 90-95 ft. lbs. *DO NOT REPLACE THIS BOLT WITH ONE THAT IS NOT HEAT TREATED.*

►*POWER STEERING TOE-IN ADJUSTMENT NOTE:* When adjusting toe-in on Power Steering cars, operate engine which will permit steering pump oil pressure to center valve spool in control valve

DESCRIPTION: Similar to design used on previous models. Upper and lower control arms are connected to steering knuckles by a trunnion assembly and coil springs are mounted between spring seat attached to top of steering knuckle and seat in wheelhouse panel. Shock absorbers are mounted between lower control arm and bracket on wheelhouse panel. Eccentric bolts are used at inner ends of lower control arm for camber and caster adjustment.

ADJUSTMENT

CHECKING & ADJUSTING: *ADJUSTMENT NOTE - Eccentric bolts used at inner ends of lower control arm for camber and caster adjustment on all models.*

Tire Inflation: (1955-56 All Models) - 24 lbs. (Front & Rear) (1957) - Hudson & Nash, 24 lbs. (Front), 20 lbs. (Rear). Rambler 24 lbs. (Front & Rear). All with tires cold.

Kingpin Inclination: 1955 Nash 6½°, Hudson 3°36', 1956-57 All Models 6½°.

Caster: **(Exc. Power Steering)** - 0° to Pos. ½° (Pos. ½° desired). **(Power Steering)** - Pos. ½° to Pos. 1° (Pos. 1° desired). *See "Camber & Caster Eccentric Bolt Adjustment" below.*

Camber: Neg. ¼° to Pos. ¼° (0° desired), all models. *See "Caster & Camber Eccentric Bolt Adjustment" below.*

►*CASTER & CAMBER ECCENTRIC BOLT ADJUSTMENT:* Lower control arm attaching bolts are provided with eccentric washers, one being attached to bolt and the other keyed to threaded end of bolt. Loosening the attaching bolt nut will permit turning the bolts and eccentrics for adjustment of camber and caster. Adjust caster first, using one bolt as necessary, then adjust camber, turning both bolts equally as required.

Toe-In: 1/16" to 3/16". Loosen clamps and rotate adjusting tube on each front wheel tie-rod equally in opposite directions. To adjust steering wheel for correct spoke position after toe-in adjustment, rotate both tubes equally in the same direction.

►*1957 TOE-IN ADJUSTING TUBE CLAMP POSITION FOR MAXIMUM CLEARANCE:* **(Series 10 & 20)** - Open end of clamp should be to front and bolt head up. **(Series 30)** - Open end of clamp should be down with bolt head to front. **(Series 80)** - Open end of clamp should be to rear with bolt head up.

Toe-Out on Turns:	**Inner Wheel**	**Outer Wheel**

REMOVAL & INSTALLATION

COIL SPRING REPLACEMENT (1955-56): Two front coil spring compressors used (KMO-735 for Rambler, J-5224 for Others) Remove two rebound bumpers from upper control arms and raise front end of car to permit spring to extend to its full rebound position Install upper section of one compressor on highest coil of spring and lower section of other compressor on lowest coil. Lower front end of car to partially compress spring with car weight (Maintain support under front end). Install remaining sections of compressors enclosing the five (Rambler), nine (Others) coils Raise front of car and remove wheel, hub, and drum as an assembly. Tighten compressors evenly until spring can be removed.

►*CAUTION:* Lip of lower spring seat must engage upper end of knuckle pin to prevent spring slipping off pin.

►*SPRING REMOVAL NOTE: To facilitate installation and removal of spring compressor tools, a spring compressor can be made from two Ambassador Series lower spring retainers and a 5/8" bolt 18" long threaded at both ends. Insert bolt through spring and install spring retainers, then draw spring together by turning nuts on bolt.*

COIL SPRING REPLACEMENT (1957): *NOTE* - **Spring seats have been added at each side so special hooks, Tool No. 3200378 can be installed for spring removal and installation.**

CONTINUED ON NEXT PAGE

1955-57 HUDSON, NASH, RAMBLER FRONT SUSPENSION (C nt.)

R m val: Raise rear of car on side opposite from which spring is to be removed and install hooks, Tool No. 3200378 in holes of ears on spring seats (if necessary, additional compression of spring can be obtained by leaning on front fender over spring). Lower rear of car, then raise front of car with a jack placed under frame at point that will allow wheel and suspension assembly to hang freely. Coil spring, upper and lower spring seats, and insulator can then be lifted out of spring support.

Installati n: If original spring is to be installed, reverse removal procedure. If a new spring is to be installed, install upper and lower cushions and spring seats on spring. Align holes in ears on upper and lower spring seats and compress spring in an arbor press to a point where hooks can be installed. Install springs on spring support, lower front of car, then raise rear of car at side opposite spring being installed.

UPPER CONTROL ARM: Removal - Remove front coil spring, (see above) Disconnect inner ends of control arm assembly from wheelhouse bracket and remove control arm spacer bolt and spacer Remove bushings from both sides of trunnion and remove control arms

Installation: Reverse removal procedure, making sure that trunnion is centered between control arms

OWER CONTROL ARM: Removal - Remove front coil spring (if not previously removed) Disconnect inner ends of control arms by removing eccentric bolts and washers at wheelhouse bracket Remove shock absorber mounting bolt at lower end and remove spacers and

CONTINUED ON NEXT PAGE

STEERING KNUCKLE ASSEMBLY

1955-57 HUDSON, NASH, RAMBLER FRONT SUSPENSION (C nt.)

grommets. Remove both trunnion bushings, then remove control arms.

Installation: Reverse removal procedure, making sure that trunnion is centered in lower control arm

►*UPPER & LOWER CONTROL ARM RUBBER BUSHING REPLACEMENT NOTE:* These bushings are not furnished separately. If replacement is necessary, the complete assembly must be installed

STEERING KNUCKLE: Removal - Remove wheel and brake drum assembly, then remove brake backing plate. Remove front coil spring (see above) Remove spacer bolt from upper control arm and shock absorber mounting bolt, spacers, and grommets from lower control arm. Remove trunnion bushings from upper and lower trunnions Remove steering knuckle assembly after disconnecting steering arm

Disassembly: Remove nut and washer securing spring lower support from knuckle and remove support and thrust bearing Unscrew lower trunnion from knuckle and remove trunnion seal.

R assembly· Reverse disassembly procedures and note the following: Screw lower trunnion onto steering knuckle until there is approximately ¼" clearance between shoulder on knuckle and lower trunnion.

1954-57 HUDSON & NASH REAR SUSPENSION

Nash Statesman (1954-57)
Nash Ambassador (1954-57)
Hudson (1955-57)

►*1954-55 RAMBLER NOTE: Rear suspension on these models is conventional type with leaf type springs and Hotchkiss drive*

DESCRIPTION: Special coil spring type with springs insulated by rubber cushions at top (in body) and at lower end (at spring seat on axle housing). Direct acting shock absorbers are mounted within springs and Stabilizer is used to maintain alignment

REMOVAL OF SPRING & SHOCK ABSORBER: Lift rear of body until all weight removed from springs, remove two nuts on shock absorber bolts at rear axle. Lift rear of body sufficiently to free shock absorber bolts from axle housing, remove lower spring saddle. Swing spring, shock absorber, and lower spring seat to one side, lower spring and lift out. To remove shock absorber after spring removed, remove nuts and rubber grommets on upper mounting stud within body, lower shock absorber and remove from below.

INSTALLATION OF SPRING & SHOCK ABSORBER: Install grommets and nuts on upper end of shock absorber in body, assemble bolts, bushings and spacer on lower end of shock absorber. Install upper rubber cushion on spring by placing projection or tab on cushion between stationary end coil of spring and first movable coil and rotating cushion until flat end of stationary coil is tight against shoulder of tapered projection on spring (CAUTION—positioning necessary to prevent contact between first closed coils of spring in operation). Install lower spring cushion similarly

SPRINGS: Springs are ground flat at upper and lower ends Same type springs used on all models.

Rear Spring Specifications

Model	Free Height	Loaded Height
All Models (Std)	17 7/8"	10 9/16"
Heavy Duty (1954)	15 1/2"	10 17/32"
Heavy Duty (1955-57)	16 3/4"	11 1/4"

►*NOTE When heavy duty springs are installed, heavy duty shock absorbers must be installed at front and rear.*

►*NOTE*—When heavy duty rear springs are installed, heavy duty shock absorbers must be installed in both front and rear.

1958-60 RAMBLER FRONT SUSPENSION

Rambler, Series 10, 20, 80 (1958-60)
Rambler American (1958-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*1958 RAMBLER AMERICAN FRONT SPRING UPPER AND LOWER SEAT PRODUCTION CHANGE:* Beginning with Car Serial No M-12686, new spring seats, Part No 3155664 (upper), No 3155668 (lower) are being used in production The later type seats have "ears" for use with Spring Clamp, Tool 3200377 and are similar to seats used on other Rambler models *See "Coil Springs" below*

►*1958 RAMBLER AMERICAN UPPER CONTROL ARM TRUNNION PRODUCTION CHANGE* Beginning at Car Serial No M-2253, upper control arm trunnion bronze bushings, Part No 3155455 were replaced in production with needle bearings, Part No 3133514 The later type bearings may be installed in place of the bronze bushings on early production cars

►*1958 RAMBLER SERIES 5810 UPPER CONTROL ARM TRUNNION BEARING CHANGE (To prevent road shock and steering wheel movement on rough roads):* New Trunnion Assemblies, Part No 3155439, which have bronze bushings in place of the former needle bearings, were used in production beginning with Car Serial No D-416950 Later type trunnions may be used for service replacement on cars built before the above serial number

►*LOWER CONTROL ARM THROUGH BOLT TIGHTENING CAUTION·* The lower control arm through bolt which also acts as the front shock absorber lower anchor (on all models) is specially heat treated and must be properly tightened to 110-125 ft lbs *DO NOT REPLACE THIS BOLT WITH ONE THAT IS NOT HEAT TREATED*

►*TOE-IN ADJUSTMENT NOTE (Cars with Power Steering)* Operate engine to permit steering pump oil pressure to center valve spool in control valve assembly before checking or adjusting toe-in

DESCRIPTION: Upper control arms are connected to steering knuckles by trunnion assemblies On Rambler American, upper trunnion is integral with front spring lower support On other models, coil spring lower support is threaded on upper trunnion Coil springs are mounted between support on top of steering knuckle and seat in wheelhouse panel Shock absorbers are mounted between lower control arm and bracket on upper control arm inner shaft (Rambler American), between lower control arm and bracket on wheelhouse panel (Series 10, 20, 80) Camber and caster adjustments are made by eccentric bolts, (Exc Rambler American), shims (Rambler American) located at inner ends of lower control arms

ADJUSTMENT

CHECKING & ADJUSTING: *CAMBER & CASTER ADJUSTMENT NOTE - Eccentric bolts at inner end of lower control arms (series 10, 20 & 80), shims between lower control arm shaft and frame (Rambler American) control camber and caster adjustment*

Tire Inflation: 24 lbs front & rear (cold)

Steering Axis Inclination: 8° (Rambler American), 6°11' (Series 10 20 & 80) Not adjustable

Caster: (Exc. Power Steering) - 0° to Pos ½° (Pos ½° preferred) **(Power Steering)** - Pos ½° to Pos 1° (Pos 1° preferred) *See "Camber & Caster Adjustment" below*

Camber: Neg ¼° to Pos ¼° (0° preferred) *See "Camber & Caster Adjustment" below*

►*CAMBER & CASTER ADJUSTMENT (SERIES 10, 20 & 80)* Lower control arm attaching bolts are provided with eccentric washers, one being attached to the bolt and the other keyed to threaded end of bolt Loosening attaching bolt nut will permit turning the bolt and eccentrics for adjustment of camber and caster Adjust caster first, using one bolt as necessary, then adjust camber, turning both bolts equally as required

►*CAMBER & CASTER ADJUSTMENT (RAMBLER AMERICAN)* "U" type spacers are installed between lower control arm pivot bar and mounting surface Increasing number or thickness of spacers at either front or rear mounting bolt permits adjusting caster angle Increasing or decreasing equally at both front and rear bolts will change camber angle *NOTE - Lower control arm pivot bar must be loosened before making camber or caster adjustments When reinstalling brace, tighten attaching bolts to 90-95 ft lbs*

CONTINUED ON NEXT PAGE

1958-60 RAMBLER FRONT SUSPENSION (Continued)

Toe-In: 1/16-3/16" (Exc Series 20 & 80), 3/16" (Series 20 & 80) On all models (Exc Series 20), loosen clamps and rotate adjusting tube on each front wheel tie rod equally in opposite directions On Series 20, loosen clamps and rotate adjusting tube on steering drag link adjacent to right side idler lever Adjust steering wheel for correct spoke position by rotating adjusting tubes equally in same direction (Exc Series 20), by rotating adjusting tube on pitman arm-to-steering arm link (Series 20)

►*TOE-IN ADJUSTING TUBE CLAMP POSITIONING FOR MAXIMUM CLEARANCE* Open end of clamp should be toward REAR (Exc Series 20), toward FRONT (Series 20) when clamp bolt is tightened

Toe-Out in Turns: 1958 Models - With inner wheel at 20°, outer wheel should be 17°40' (Rambler American), 17°17' (Series 10), 17°14' (Series 20), 17°28' (Series 80) Not adjustable
1959-60 Models - With inner wheel at 25°, outer wheel should be 21½° (American), 22° (Others) Not adjustable

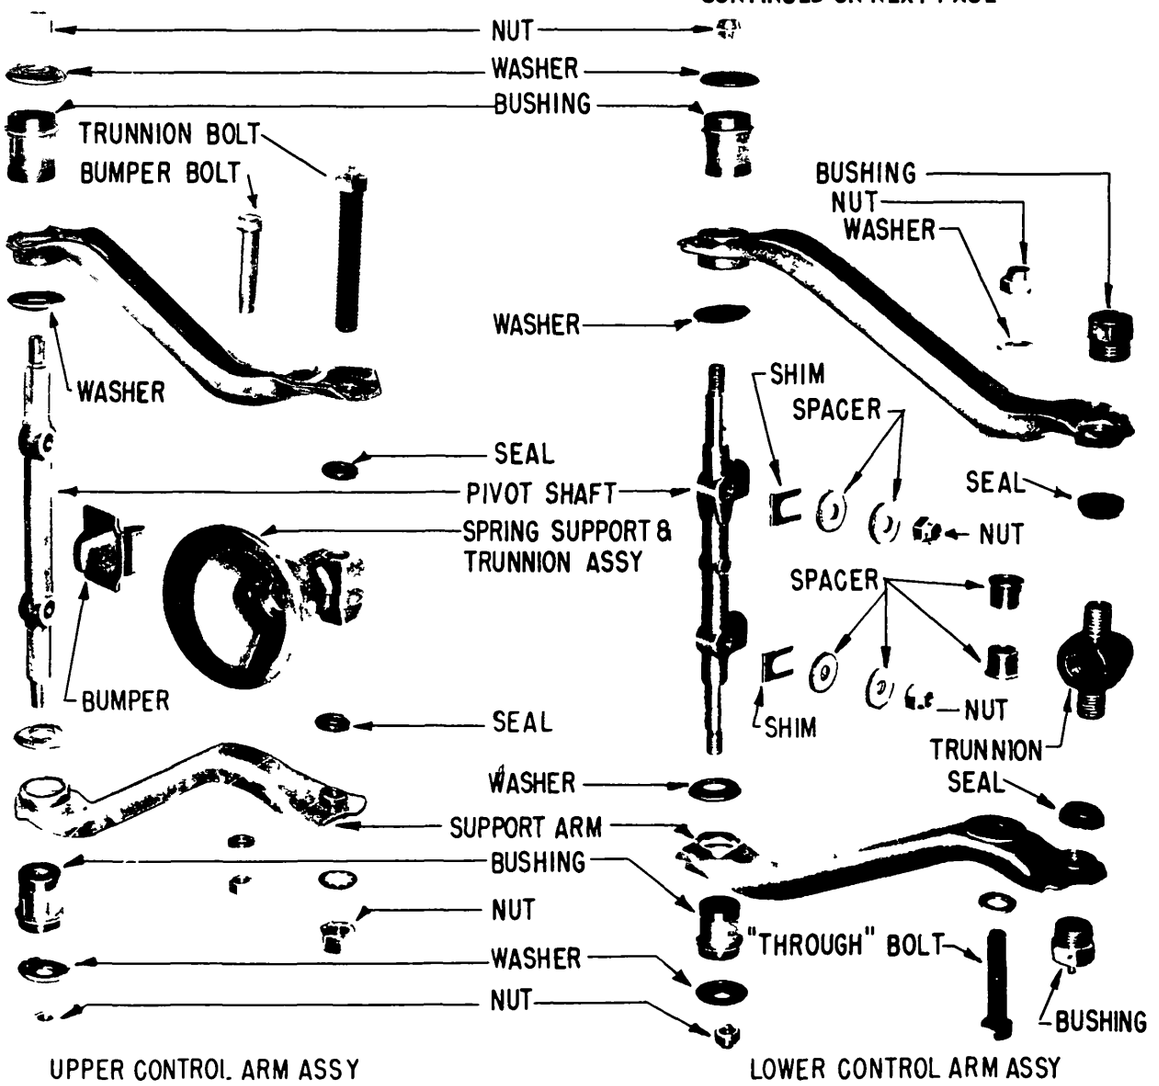
REMOVAL & INSTALLATION

FRONT COIL SPRING: *NOTE - Early 1958 Rambler American models do not have coil spring seats with "ears" for attachment of spring compressor tools such as used on other Rambler models*

Removal (Rambler American Before 1958 Serial No. M-12686): With weight of car on wheels, install two front spring compressors, Tool J-8081, on spring to enclose nine coils, then compress spring evenly Raise and support front end of car with a jack placed under frame side rails and remove spring

Installation (Rambler American Before 1958 Serial No. M-12686): If original spring is being reinstalled, reverse removal procedures If a new spring is to be installed (or compressor, Tool J-8081 is to be removed), spring can be compressed using two spring seats and a ½" x 17½" threaded rod as follows Install spring seats on each end of spring and insert rod through center of seats and spring, then install necessary washers and nuts and draw spring together Install Spring Clamp, Tool J-8081 to enclose nine coils and remove supplemental compressing tool, then install spring *NOTE - Lip of lower spring seat must engage seat of knuckle pin to prevent spring from shifting*

Removal (Rambler American After 1958 Serial No M-12686 & 1958-60 Series 10, 20, 80 Rambler): Raise rear of car on side opposite front spring to be removed and install Tool J-7842 (Rambler American), Tool J-7389 (Series 10, 20, 80) on ears of upper and lower spring seats *NOTE - If additional compression of spring is necessary to install tool, apply weight to front fender over spring being removed* Lower rear of car, then raise front of car with a jack placed under frame at a point that will allow wheel and suspension to hang free Coil spring, upper and lower spring seats, and insulator can then be lifted out of spring support



Installation (Rambler American After 1958 Serial No. M-12686 & 1958-60 Series 10, 20, 80 Rambler): If original spring is being reinstalled, reverse removal procedure If a new spring is to be installed, install upper and lower cushions and spring seats on spring, then align holes in ears on upper and lower seats and compress spring in an arbor press to a point where compressing tool can be installed Install spring in car

CONTINUED ON NEXT PAGE

RAMBLER AMERICAN CONTROL ARM ASSEMBLIES

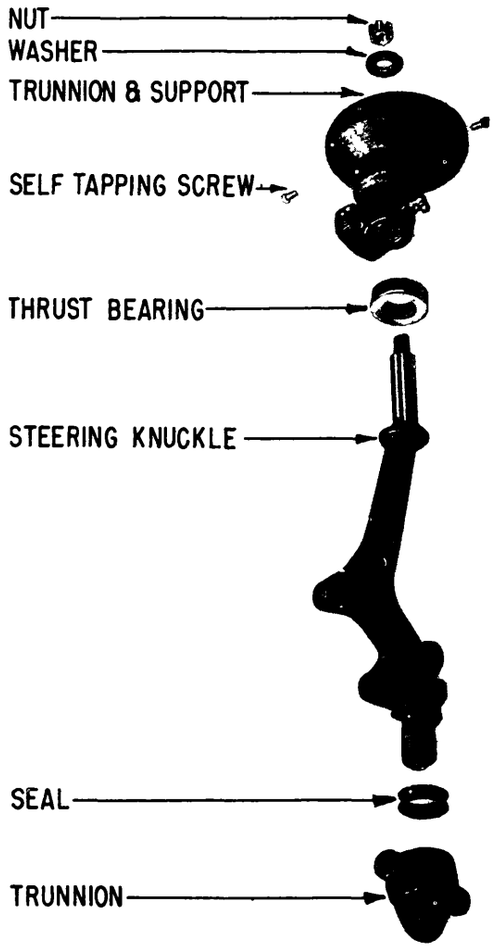
1958-60 RAMBLER FRONT SUSPENSION (C ntinu d)

SHOCK ABSORBERS: Removal - On Rambler American, loosen lower control arms at pivot bar ends. On all models, disconnect shock absorber from upper bracket, then remove through bolt in lower suspension arm and remove shock absorber.

Installation: Reverse removal procedure and tighten through bolt in lower suspension arm to 110-125 ft. lbs.

►*SHOCK ABSORBER APPLICATION: See "Shock Absorbers" on Car Model pages.*

UPPER CONTROL ARM (SERIES 10, 20 & 80): Re- m val - Upper control arm may be removed without removing the entire assembly. Remove front spring (see above), then remove front or rear arm by disconnecting at trunnion, wheelhouse panel, and control arm spacer. Both front and rear arms may be removed as an assembly by disconnecting them from mounting bracket. Remove lower spring seat support, lock pin, and nut from knuckle pin. Upper control arms with spacer and upper trunnion may then be removed from car.



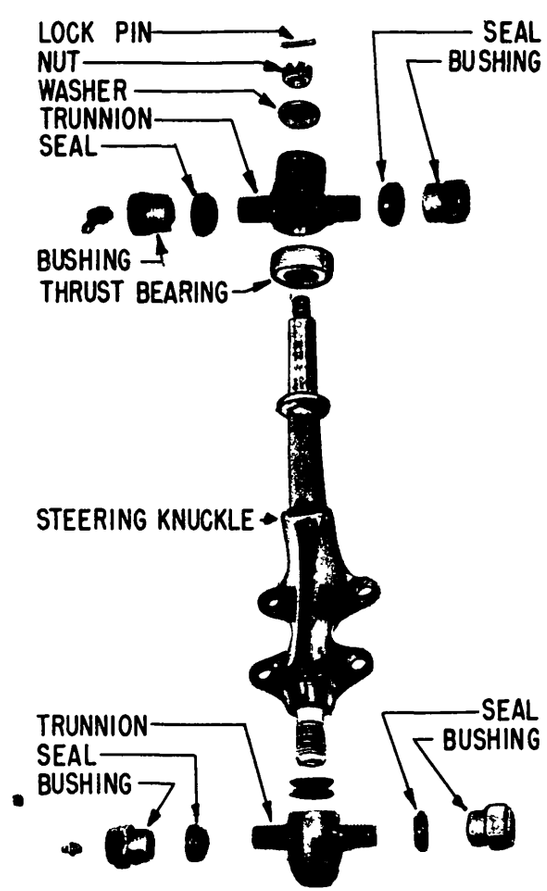
Installation: *(NOTE - Upper and lower control arm bushings are not furnished separately. If replacement is necessary, the complete assembly must be installed).* Install upper control arm by reversing removal procedure.

UPPER CONTROL ARM (RAMBLER AMERICAN): Re- m val - Remove front spring (see above), then remove screw attaching outer end of control arms to trunnion. Disconnect shock absorber at lower end by removing the control arm through bolt. Remove bolts securing control arm pivot shaft to bracket and remove shock absorber upper mounting bracket, then remove control arm.

Installation: Reverse removal procedure. *CAUTION - The trunnion screw has a larger thread diameter at head than at the end and must be installed into same control arm when being assembled to insure a tight fit.*

LOWER CONTROL ARM (SERIES 10, 20 & 80): Re- m val - Arms may be removed individually after removing front spring (see above). Disconnect at lower shock absorber mounting, trunnion, and at mounting bracket.

Installati n: Reverse removal procedure and note the following: Install and tighten bushings at outer end of control arms and onto trunnion centering the trunnion between control arms. *CAUTION - Shock absorber lower mounting bolt is specially heat treated and must be tightened to 110-125 ft. lbs. Do not substitute this bolt except with special heat treated type.*



RAMBLER AMERICAN STEERING KNUCKLE ASSEMBLY

LOWER CONTROL ARM (RAMBLER AMERICAN): Re- moval - Remove front spring (see above), then disconnect shock absorber at lower end. Remove threaded bushings from trunnion and disconnect control arm inner pivot shaft from bracket. *NOTE* - Camber and caster adjusting spacers are located between pivot arm and bracket.

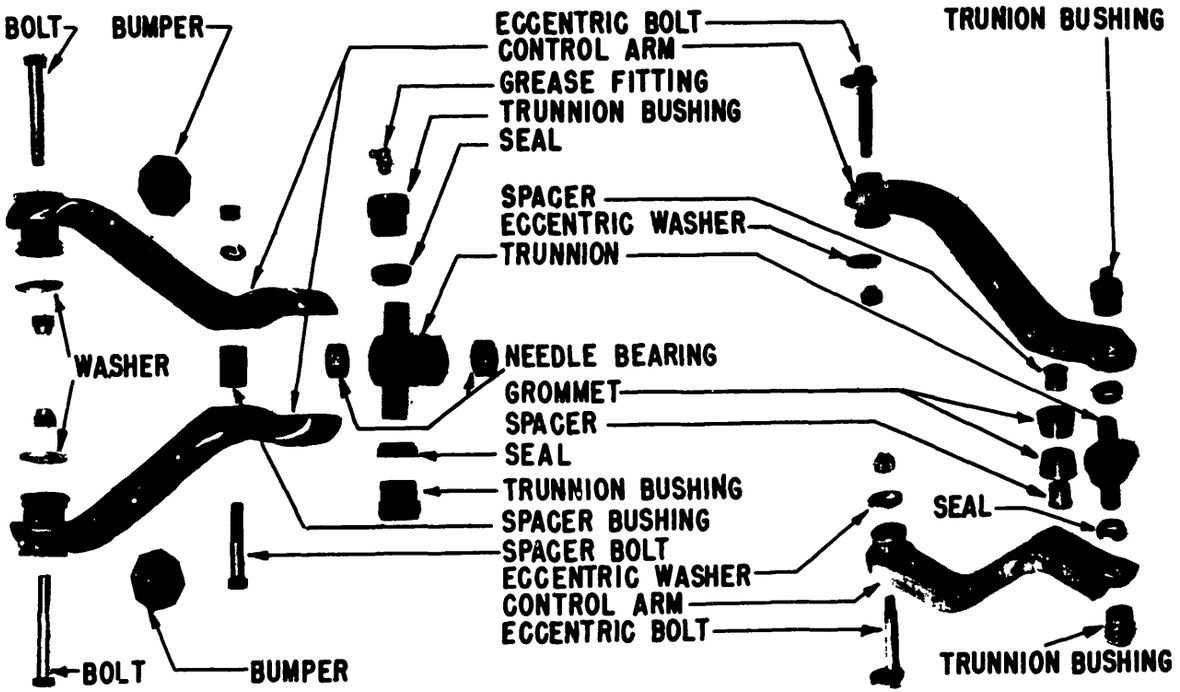
Installation: See Series 10, 20 & 80 installation (above), and tighten trunnion bushings to 125 ft. lbs.

CONTROL ARM BUSHINGS (RAMBLER AMERICAN): Re- plac m nt - Rubber bushings are pressed into control arms. Do not turn or twist bushings when removing or installing as bushings must be a tight press fit in arms. *(NOTE - Bushings may be id ntifi d by the ight shoulders running lengthwis on out r sh ll f upper control arm bushing and the plain out r sh ll on l w r control arm bushing).* Remove bushings with a 13/16" socket and a 1 7/16" socket by installing the sockets and control arm (bushing end) in a vise, then press bushing into large socket with the smaller socket. Install bushing using a 1¼" socket and a 1 7/16" socket. Press bushing into control arm with the 1¼" socket until flange on bushing is ½" from arm on upper control arm. On lower control arm, bushing is pressed in until flange is against arm.

RAMBLER (EXCEPT AMERICAN) STEERING KNUCKLE ASSEMBLY

STEERING KNUCKLE (SERIES 10, 20 & 80): R m val - Remove front spring, then remove front wheel and brake drum. Remove brake backing plate. Unscrew spring

CONTINUED ON NEXT PAGE



1958-60 RAMBLER FRONT SUSPENSION (C nt.)

lower support from upper trunnion, then remove pin from castellated nut at top of steering knuckle. Unscrew steering knuckle from lower trunnion and withdraw knuckle from upper trunnion.

Installati n: Reverse removal procedure and note the following: Screw knuckle into lower trunnion until there is approximately ¼" clearance between shoulder on knuckle pin and the trunnion. Tighten castellated nut at upper end of knuckle so there is a minimum of end-play and knuckle rotates freely.

STEERING KNUCKLE (RAMBLER AMERICAN): Rem val - Remove front spring, then remove front wheel and brake drum assembly Remove brake backing plate. Remove two self tapping screws from spring lower support (screws located 180° apart just below flared portion of support). Rotate support to line up pin through castellated nut, with holes in support, then drive pin out through one of the holes. Remove castellated nut and washer and raise upper support arm to free support from knuckle. Unscrew steering knuckle from lower trunnion and withdraw knuckle.

Installati n: Reverse removal procedure and note the following: Screw knuckle into lower trunnion until there is approximately ¼" clearance between shoulder on knuckle pin and the trunnion. Tighten castellated nut on upper end of knuckle so there is a minimum of end-play and knuckle rotates freely. Line up pin holes in knuckle with slots in nut and holes in spring lower support and install pin. Install self tapping screws in both holes of lower spring support.

RAMBLER (EXCEPT AMERICAN) CONTROL ARM ASSEMBLIES

1956-60 RAMBLER REAR SUSPENSION

Rambl r, Except American (1956-60)

DESCRIPTION: Rear springs are mounted between seats on rear axle housing and seats on car underbody and are held in position by weight of car on springs and by extended limits of shock absorbers. A rear stabilizer bar connected between car underbody on right side and a bracket on left side of rear axle housing prevents prevents lateral movement of rear axle assembly. Shock absorbers are mounted adjacent to rear springs on forward side of rear axle housing and are connected to a bracket on rear axle housing and to car underbody assembly. Rear wheel driving force is transmitted to car body by a torque tube between rear axle housing and transmission.

SHOCK ABSORBERS: Removal - Disconnect shocks from car underbody and from bracket on rear axle housing and remove shock.

Installation: Reverse removal procedure.

►*SHOCK ABSORBER APPLICATION: See "Shock Absorbers" on Car Model pages.*

REAR COIL SPRINGS: Removal - Raise and support rear of car with a jack stand placed under car underbody, then raise rear axle assembly to approximately normal ride position. Disconnect shock absorbers at bracket on rear axle, then lower rear axle sufficiently to free springs from seats. Springs can then be lifted out. *CAUTION* - When lowering rear axle assembly be careful not to lower it to the point where a strain will be placed on torque tube connection at transmission.

Installation: Reverse removal procedure.

Rear Spring Application

Model & Series	Part N .
All Series 10 & 20, Exc.Sta.Wgn.(Std.)	ℂ 3144929

All Series Sta. Wgn. (Std.)	3147610
All Series, Exc. Sta. Wgn. (Air Susp.)	3155786
All Series Sta. Wgn. (Air Susp.)	3155393

ℂ - For heavy duty, use Part No. 3147610.

1954 OLDSMOBILE

All S ri s (1954)

DESCRIPTION: Independent linked parallelogram type with double acting shock absorbers integral with upper control arm assembly.

CHECKING & ADJUSTING: Check and adjust front wheel bearings, then proceed as follows:

Tire Inflation: 24 lbs. (front); 22 lbs. (rear).

Kingpin Inclination: 5°51'10" at 0° camber. Not adjustable.

Caster: Must be equal within ½° on both sides. Machined bosses provided on front side of knuckle support for protractor mounting.

Caster Specifications

Oldsmobile (All Models)	0° to Neg. ¾°

To Adjust—Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting on front bushing of upper support pivot pin, insert Allen wrench J-720 through lubricant fitting hole and turn upper pivot pin clockwise to increase caster, counter-clockwise to decrease caster. CAUTION—Pin must always be turned in complete turns only to avoid disturbing camber adjustment (below).

Camber: Camber adjustment (upper pivot pin) eccentricity is 1/16". 3/32" pin is available from the Parts Dept. and can be installed if regular 1/16" pin does not give sufficient range of adjustment.

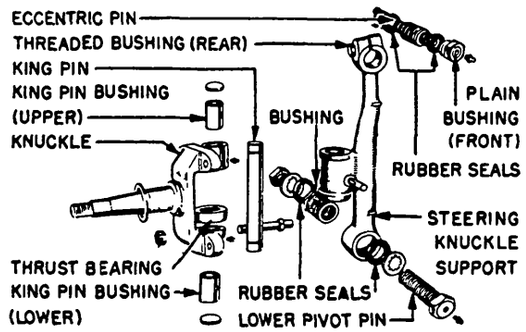
Camber Specifications

All Models	Neg. ¾° to Pos. ¾°

①—New Car limits Neg. ¼° to Pos. ¾°.

To Adjust—Same as for Caster (above) except that entire range of adjustment secured in ½ turn of eccentric pivot pin. CAUTION—Do not turn pin more than ½ turn when adjusting camber to avoid disturbing caster adjustment.

Toe-In: Measure 9-10" above floor with wheels turned straight ahead.



Toe-In Specification

Oldsmobile (All Models)	1/16-1/8"

To Adjust—Loosen clamp bolts at wheel end of each tie rod, turn tie rod adjuster on each rod equally. On Oldsmobile, turn both adjusters in direction opposite to that in which wheel revolves to increase toe-in.

Toe-Out on Turns: With outer wheel turned exactly 20°, inner wheel 23° ± ½°. No adjustment.

SERVICING: Lower Control Arm & Pivot Shaft. Serviced as an assembly and not interchangeable on right and left sides of car. Pivot shaft at inner ends of control arms can be removed by taking out bushing in each arm. To install shaft, install tool J-1052 or block between arms adjacent to shaft

OLDSMOBILE FRONT SUSPENSION

eyes so that distance between inner faces of arms at shaft eyes is exactly 11½" (necessary to prevent distortion of arms when bushings installed). Install shaft with seal on each end adjacent to mounting bracket, thread bushing in on shaft and in arm simultaneously (new bushings cut their own thread in arm as they are turned in), tighten bushings with 150 lb. pull on 16" wrench (200 lbs. on 12" wrench) so that there is no clearance between bushing flange and control arm. See that distance between shaft bracket mounting holes and inner face of control arm is exactly 1½" at each end (turn shaft to centralize), and that seal ends lap over bushings.

Knuckle Support Lower Pivot Pin—To install pin, slip rubber seal over outer end of each lower control arm, center knuckle support between lower control arms (approximately ⅛" between end of bushing and front arm, same distance between head of bushing and rear arm). Screw pivot pin through front arm, knuckle support bushing, rear arm, install nut on rear end of pin. Pull seals down over end of arms so that they seat on pin between arm and bushing at each side.

Knuckle Support Upper Pivot Pin—To install, center knuckle support in upper control arm yoke, screw pivot pin in until larger center section is centered in knuckle support, tighten clamp bolt. Install seal on pin at each side, start front bushing in on pin, then screw rear bushing in control arm and on pin and tighten securely. Turn front bushing in until clearance between front face or arm and head of bushing 1/32", tighten clamp bolt.

Kingpin Installation (Oldsmobile)—Bushings should be installed with oil hole lined up with oil hole in knuckle support and short groove on inner surface leading from oil hole to outer end of bushing (up on top bushing, down on lower bushing). Bushings should be burnished with Tool Set J-1061 and line-reamed to size with Tool HM-592.

SPRINGS: Lower end of spring not ground flat and must be installed with end coil fitted into recess in lower spring seat. Upper end of spring is ground flat. CAUTION—Spring must be installed with flat (ground) end up and lower end fitted in spring seat.

1954 Springs

88 (Without Air Cond.)	565270
88 (With Air Cond.)	564262
Super 88 Exc. Conv. (Without Air Cond.)	564234
Super 88 Conv.	565271
Super 88 (With Air Cond.)	564262
98 Exc. Conv. (Without Air Cond.)	564235
98 Conv.	565271
98 (With Air Cond.)	566550

Part Number Location—Stamped on lower end of coil.

Color Mark—Consists of one or two paint daubs on one spring coil.

COIL SPRING REPLACEMENT: Support car frame with car stands, center jack under lower control arm pivot shaft and disconnect stabilizer link. Disconnect pivot shaft from front cross-member. Lower jack from under pivot shaft, allowing control arm to drop out of position, and remove spring.

Installation—Reverse removal procedure and be sure that flattened top coil is toward top and centralized by four lugs on cross-member. Bottom must index with hole in spring seat.

SHOCK ABSORBER REPLACEMENT: Place jack under knuckle support and raise car and remove wheel. Remove upper pivot pin. Remove the four shock absorber mounting bolts (nuts inside cross-member must be held from turning). Remove shock absorber.

Servicing (Front Shock Absorbers): Unsatisfactory ride control may be due to lack of fluid or malfunction of shock absorber. (NOTE—Presence of an appreciable amount of oil under shaft bearings on outside of shock absorber usually indicates shaft bushings are worn or oil seal has failed. In either case, unit should be replaced without further examination). To test shock absorber action without removing from car, proceed as follows: Be sure shock absorber is securely mounted, then disconnect shock absorber arm at upper pivot pin. Holding shock absorber at approximately the same angle as installed on car, move shock absorber through complete travel. There should be no free travel in shock absorber arm and amount of force required to move arm up and down should be almost equal. If control of shock absorber defective, fluid level should be checked and shock filled if found to be low (See Filling Front Shock Absorber below). If fluid is at proper level, replace shock absorber. NOTE—If shock absorbers checked while removed from car, they should be checked in same position as when mounted.

Filling Front Shock Absorber: If shock absorber off car, place shock absorber on mounting block with filler plug tilted upwards approximately 15° from horizontal position. Remove filler plug and make sure shock is completely full of fluid.
CAUTION—It is important that front shock absorber be filled through filler plug with shock in above position, otherwise air may be locked in shock absorber.

Installation—Reverse removal procedure and check front end alignment.

Form 54 A

1955-56 OLDSMOBILE

All Series (1955-56)

►CHANGES & CORRECTIONS

►*1955 PIVOT PIN PRODUCTION CHANGE (To Eliminate Need for Lockwashers)* Effective approximately July 1, 1955 new upper and lower pivot pins are used in production. New pins have head of bolt undercut, and a higher pitch thread diameter is used immediately under the head of the bolt. Changes cause locking action when bolt is tightened and eliminate need for lockwashers.

DESCRIPTION: New design independent "parallelogram" type with shock absorbers mounted within front coil springs. Shock absorbers are independent of upper control arm and can be removed and installed without disturbing upper control arm assembly.

ADJUSTMENT: Before checking and adjusting front wheel alignment, inflate tires to recommended pressure. Check front wheel bearings for proper preload. Check front wheel and tire assemblies for radial and lateral run-out. Grasp front bumper in center and raise and lower front end several times to allow frame to come to its normal level. Check front shock absorber action. All specifications below, are for car at curb weight.

Tire Inflation Pressure: 24 lbs. (front), 22 lbs. (rear)

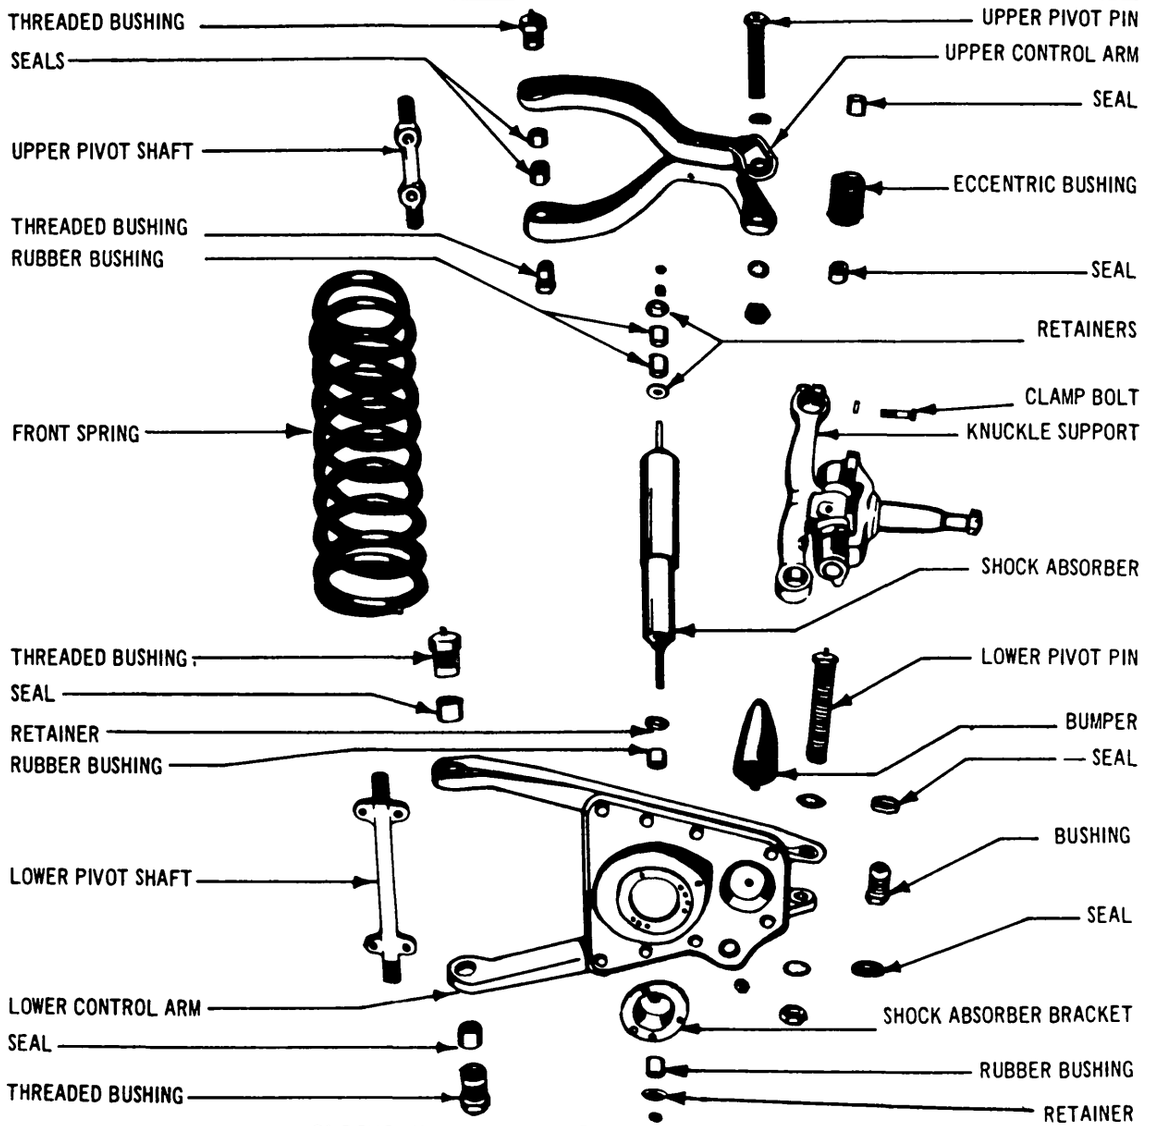
Kingpin Inclination: 5°51'10" at 0° Camber. Not adjustable.

Caster: 0° to Neg. ¾°. Variation between wheels should not exceed ½°.

Adjustment—Loosen clamp bolt at upper end of steering knuckle support and using special wrench J-5343, turn eccentric bushing in a clockwise direction to increase caster, and in a counter-clockwise direction to decrease caster. *NOTE*—Before tightening clamp bolt, adjust camber (see below).

Camber: Neg. ¾° to Pos. ¾°. Variation between wheels should not exceed ½°.

Adjustment—Same as for caster (above). Turn eccentric bushing not more than ½ turn in either direction from point where correct caster secured. *NOTE—The entire range of camber adjustment is secured within ½ turn of eccentric bolt.*



Toe-In: 1/16" to 1/8"

Adjustment—Loosen clamp bolts at each end of steering tie rod adjustable sleeves. With steering wheel set in straight ahead position, turn tie rod adjusting sleeves to obtain the proper toe-in adjustment. *CAUTION*—After adjustment completed and tie rod end ball studs are square in their seats, position tie rod-to-relay rod ball studs to bottom of slot in relay, then position clamps so bolts are below upper surface of adjusting sleeves. End of clamp must not be in slot.

Toe-Out on Turns: With outer wheels turned 20°, inner wheel should be 23°±½°. Not adjustable.

SHOCK ABSORBER REPLACEMENT: *NOTE—It is not necessary to disturb front suspension assembly.*

Removal—Remove nut and jam nut on upper end of shock absorber (*CAUTION—Flats are provided on upper stud so it can be held while loosening the nuts*). Remove three capscrews and lockwashers attaching shock absorber bracket to lower control arm, and remove shock absorber out through lower control arm spring seat.

OLDSMOBILE FRONT SUSPENSION ASSEMBLY

Installation—Reverse removal procedure.

FRONT STABILIZER: Removal—Disconnect stabilizer linkage, each side, by removing nut from top of link-bolt. Pull out bolt from bottom of linkage, and remove retainers, grommets, and spacer. Remove stabilizer bracket to frame bolts and remove stabilizer bar, rubber bushings and brackets.

Installation—Reverse removal procedure and note the the following. Rubber bushings should be positioned squarely in brackets and the nut retaining the stabilizer link assembly should be drawn down to the limit of the threads. *CAUTION—Never lubricate stabilizer bushings.*

COIL SPRINGS: Removal—Support car with floor stands. Disconnect stabilizer link from lower control arm and remove rubber bumper from lower control arm. Remove shock absorber (see above). Center jack pad under lower control arm pivot shaft and raise jack until it just contacts shaft, then disconnect pivot shaft from front crossmember. Lower jack slowly, allowing control arm to drop out of position until spring is fully extended and remove spring.

Installation—Place jack pad under lower control arm pivot shaft. Position rubber insulator over pilot in crossmember. Hold the upper end (flat end) of coil

CONTINUED ON NEXT PAGE

Form 54 B

1955-56 OLDSMOBILE (Cont.)

spring in crossmember and raise lower control arm until spring seat contacts lower coil of spring, then rotate spring so end of bottom coil will index in hole provided in spring seat. Raise control arm gradually, checking to see that spring is seated correctly top and bottom, and insulator is in place. Use a drift punch to line up pivot shaft with bolt holes in crossmember and install bolts. Tighten to 55-60 ft. lbs. Connect stabilizer link, and install shock absorber

▷*COIL SPRING IDENTIFICATION NOTE:* Spring part number is stamped on the outside of one of the end coils.

UPPER PIVOT PIN & ECCENTRIC BUSHING: Removal–Place jack under lower control arm and raise wheel off floor. Remove wheel and loosen knuckle support clamp bolt. Remove nut and washer from front end of pivot pin and remove threaded pivot pin. *(CAUTION–*To prevent damage to brake hose, fasten knuckle support to upper control arm with a short piece of wire). Remove threaded eccentric bushing from knuckle support (eccentric has left hand thread).

Installation–Position pivot pin rubber seal over the outer ends of upper control arm to facilitate their installation over the pivot pin after assembly. Install eccentric bushing from front into knuckle support so that the threaded outer diameter of bushing is centralized; then tighten clamp bolt to keep bushing from turning. Centralize knuckle support between forked ends of upper control arm and install pivot pin with shake-proof lock washer from rear. Install nut and tighten to 50-60 ft. lbs. Check to be sure pivot pin bolt head and nut are tightened securely against metal of control arm. Using a heavy wire or other hooked tool, snap rubber seals over end of control arm and into place on pivot pin. Lubricate pivot pin, install wheel, and check front end alignment.

▷*PIVOT PIN NOTE: See Production Change above.*

LOWER PIVOT PIN & BUSHING: Removal–Place jack under lower arm, raise wheel off floor, and remove wheel. Remove nut and lockwasher from front end of lower pivot pin. Remove pin and bushing (use a long handle socket wrench to remove bushing and bear down with other hand on brake drum hub when working on left hand side).

Installation–Position pivot pin rubber seals over forked outer ends of lower control arm. Install bushing into front of knuckle support and seat tightly. Centralize lower pivot pin bushing with knuckle support between forked ends of lower control arm and install pivot pin with shake-proof washer from the rear and tighten to 50-60 ft. lbs. *(NOTE–*When knuckle support is properly spaced between ends of lower control arm there should be approximately 1/8" clearance between ends of bushing and inner surface of the front and rear control arm). Install a shake-proof washer and pivot pin nut and tighten securely.

▷*PIVOT PIN NOTE: See Production Change above.*

LOWER CONTROL ARM PIVOT SHAFT: Removal–Remove front coil spring (see above). *(NOTE–Before removing pivot shaft, loosen the bushings).* Unscrew pivot shaft bushings and remove shaft from lower control arm assembly. *NOTE–*The lower control arm pivot shaft bushings have threads on the inside and outside of the bushing. The inside of the bushing threads onto the pivot shaft, but the bushing cuts its own threads in the lower control arm

Installation–Install rubber seals on ends of pivot shaft and place shaft in lower control arm assembly. Start bushing on pivot shaft and into arm at same time, tighten bushing in place. Center pivot shaft between control arms and install the other bushing as above, being sure threads index so there is no bind. The distance between the center of the pivot shaft bolt holes and the inside face of the arm should be 1½" at each end. Turn pivot shaft as necessary to centralize. Position front coil spring on spring seat and complete assembly (see Coil Springs above).

LOWER CONTROL ARM: Removal–Remove coil spring (see above). Remove lower pivot pin and remove pivot shaft bushings and shaft.

New Control Arm–Place tool J-1052 in position between forks of control arm, and expand until there is a distance of 11½" between inside surface of inner ends of control arm. Apply chassis lubricant to pivot shaft threads and install rubber seals on shaft. Position pivot shaft in control arm and while holding shaft centered, start bushings on shaft and into arms. Tighten bushings until they are solidly seated against the shoulder. Remove expander tool and turn shaft, as necessary, to centralize. Install lower pivot pin. Install coil spring (see above).

UPPER CONTROL ARM & PIVOT SHAFT: Removal–Remove upper pivot pin (see above). Remove two bolts holding upper control arm to frame and remove shaft and control arm assembly. Flat washers and self-locking nuts on lower end of bolts can be reached through access hole in bottom of front crossmember. Remove threaded pivot shaft bushings and shaft

New Control Arm–Place tool J-5799 in position between forks of control arm, and expand until there is a distance of 6 9/16" between inside surface of inner ends of control arm. Apply chassis lubricant to pivot shaft threads, and install rubber seals on shaft. Position pivot shaft in control arm and while holding shaft centered, start bushings on shaft and into arms. Tighten bushings until they are solidly seated against the shoulder. Remove expander tool and turn shaft, as necessary, to centralize. Complete assembly by reversing removal procedure.

1957-60 OLDSMOBILE FRONT SUSPENSION

All Series (1957-60)

DESCRIPTION: "Ball-Joint" type with direct acting shock absorbers mounted within front coil springs.

ADJUSTMENT

CHECKING & ADJUSTING: Before checking or adjusting front wheel alignment, inflate tires to recommended pressure, check and adjust front wheel bearings, and check front wheel and tire assemblies for runout. Bounce front of car several times and allow it to come to its normal position. Check for erratic shock absorber action.

Tire Inflation: Front - 22 lbs. (Exc. Air Cond.); 24 lbs. (Air Cond.). Rear - 20 lbs. (Exc. Fiesta); 22 lbs. (Fiesta). *NOTE - On air conditioned cars with 9.50 x 14 tires, inflate front tires to 22 lbs.*

Steering Axis Inclination: 6° (1957-58); 10° (1959-60) at 0° camber. Not adjustable.

Caster: 0° to Pos. ¾° (1957); 0° to Neg. 1° (1958-60). Maximum variation between wheels must not exceed ½°. *See "Shimming Procedure" below.*

Camber: Neg. ¾° to Pos. ¾° (1957); Neg. ¼° to Pos. ¼° (1958-60). Maximum variation between wheels must not exceed ½°. *See "Shimming Procedure" below.*

Toe-In: 1/16-1/8" (1957); 0"-1/16" (1958-60). To adjust loosen clamp bolts at each end of steering tie rod adjusting sleeves. With steering wheel set in straight ahead position, rotate sleeves as necessary to obtain correct toe-in. Position tie rod to relay rod ball studs to bottom of slot in relay rod. Position inner clamps so edge of clamp is not adjacent to slot in adjusting sleeve.

Toe-Out on Turns: With outer wheel turned 20°, inner wheel should be 23°±½° (1957-59), 22°±½° (1960 Std. Strng.), 23°±½° (1960 Power Steering).

Shimming Procedure: Caster and camber adjustments are made by adding or removing shims between upper control arm mounting shaft and frame mounting bracket. To change shims, raise car to remove weight from front wheels. Loosen top and rear fasteners on fender filler plate aprons to gain access to control arm shaft mounting bolts, then loosen the bolts. Addition of shims at front bolt, or removal of shims at rear bolt, will increase positive caster. Removal of shims at front bolt, or addition of shims at rear bolt, will decrease positive caster. To change camber, add or remove shims of equal

CONTINUED ON NEXT PAGE

1957-60 OLDSMOBILE FRONT SUSPENSION (Cont.)

thickness at both mounting bolts. **Addition** of shims at **both** bolts will **increase camber. Removal** of shims at **both** bolts will **decrease camber.** See "Shim Selection" table below for approximate amount of change made by adding or removing shims. After shims have been installed or removed as necessary, tighten control arm inner shaft mounting bolts to 85-110 ft. lbs. Check adjustment

Shim Selection Table

Shim Size	Caster Change (Shim at front bolt)	Camber Change (Shim at both bolts)
.020"	3/8°	1/8°
.060"	1 1/8°	3/8°
.120"	2 1/4°	3/4°

Riding Height: Front - 10 9/16-11 7/16" (1957), 10 9/16-11 1/4" (1958), 11 3/8-12 1/16" (1959-60) from underside of front spring lower seat to underside of upper seat To measure, insert a 1/8" welding rod in drain hole on lower spring seat (inboard side of spring) and push it up to contact underside of upper spring seat Mark rod, then remove and measure distance rod inserted

Rear - 6 1/8" (1957), 6 1/8-6 13/16" (1958), 6 1/8-6 7/8" (1959-60), from top of rear axle housing to bottom of frame side rail at a point immediately to rear of rubber bumper

SHOCK ABSORBER: Upper and lower shock absorber mounting bushings are integral with the shock, and, if replacement is necessary, the complete shock absorber assembly must be replaced

Removal: Remove pivot bolt from upper end of shock absorber, then remove capscrews and lockwashers attaching shock to lower control arm Remove shock absorber out through lower control arm spring seat

OLDSMOBILE FRONT SUSPENSION ASSEMBLY

Installation: Reverse removal procedure Tighten pivot bolt to 60-70 ft lbs (1957-58), 65-75 ft lbs (1959-60)

STABILIZER: Removal - Disconnect each side of stabilizer linkage by removing nut from top of link bolt, pull out bolt from bottom of linkage, and remove retainer, grommets, and linkage Remove stabilizer bracket-to-frame bolts and remove stabilizer bar, rubber bushings, and brackets

Installation: Reverse removal procedure and note the following Rubber bushings should be positioned squarely in brackets Tighten stabilizer link nut to 8-18 ft lbs., and bracket bolts to 25-35 ft lbs

CONTINUED ON NEXT PAGE

1957-60 OLDSMOBILE FRONT SUSPENSION (C nt.)

UPPER CONTROL ARM ASSEMBLY: Removal - Raise front of car and support lower control arm with jack stands, placing the stands between lower spring seats and ball joints Remove front wheel and loosen upper control arm ball joint from steering knuckle *(see "Ball Joints" below)*. Remove ball joint stud and pull stud free of knuckle. Support hub and drum assembly to prevent weight damaging brake hose *(NOTE* - If inner control arm shaft is to be removed, loosen shaft bushings at this time). Remove inner control arm shaft-to-frame attaching bolts, nut, lock plate, and wheel alignment shims (retain shim pack found at each bolt so it may be replaced in the same location) Remove arm assembly and inner shaft from car

Disassembly: *(NOTE* - The ball joint assembly is riveted to control arm and should not be removed If necessary to replace either the control arm or ball joint, the en-'ire assembly should be replaced) Remove control arm inner shaft bushings and shaft from control arm

R assembly: Apply chassis lubricant to threads of inner shaft and install rubber seals Position inner shaft in control arm and, while holding shaft centered, start bushing on shaft and into arms. Tighten bushings until they are solidly seated. Rotate inner shaft so that shaft bolt holes are centralized in control arm (centerline of bolt hole should be approximately 1 11/16" (1957-58), 1 5/16" (1959-60), from edge of boss on arm)

Installation: Install control arm inner shaft on frame and install attaching bolts, nuts, and lock plate with the original alignment shims installed between inner shaft and mounting bracket on frame Tighten nuts to 100-110 ft lbs Remove temporary support from hub and drum assembly, then connect ball joint to steering knuckle. Tighten ball joint stud nut to 40 ft lbs (minimum) and install cotter pin (tighten nut further as necessary to install cotter pin) Install wheel and lower car Check alignment and adjust if necessary

LOWER CONTROL ARM ASSEMBLY: *(NOTE* - If ball joint is suspected of being worn, check by attempting to chuck top of wheel in and out with weight of car on wheels Under other conditions the lower ball joint will appear to be worn regardless of its actual condition)

► ***1960 LOWER CONTROL ARM REMOVAL NOTE: When removing lower control arm it is not necessary to install Tool J-6509 in shock absorber mounting in spring seat.***

Removal: Raise front of car and support with floor stands Remove wheel assembly and disconnect stabilizer bar from lower control arm Remove shock absorber (see above) Install Tool 6509 in shock absorber mounting hole in spring seat Raise floor jack until it supports lower control arm between spring seat and ball joint Remove lower ball joint from control arm *(see "Ball Joints" below)*. Slowly lower floor jack until spring is fully extended and remove spring. Remove control arm inner shaft-to-crossmember attaching bolts and remove assembly from car

Disassembly: *(NOTE* -The ball joint assembly is riveted to control arm and should not be removed If necessary to replace either the control arm or ball joint, the entire assembly should be replaced) Remove inner shaft bushings and shaft from control arm assembly

Reassembly: *(NOTE* - If a new lower control arm is to be installed, the bushings must cut their own thread in the new arm. To prevent arms from moving inward during bushing installation, Tool J-1052 must be installed between front and rear arms until distance between inner surfaces of inner ends of control arm assembly is 11½" If the old arm is to be installed it will not be necessary to use expander tool) Apply chassis lubricant to inner shaft threads and install rubber seals on shaft Position inner shaft in control arm, and while holding shaft centered, start bushings on shaft and into arms *(NOTE* - If threads are being cut in new control arm assembly, apply white lead to bushing) Tighten bushings until they are solidly seated against shoulder If expander used, remove it from the assembly and rotate shaft so bolt holes are centralized in control arm (centerline of bolt holes should be approximately 1½" from edge of bushing boss on arm)

Installation: Connect control arm inner shaft to frame crossmember and tighten attaching bolts 65-75 ft lbs (1957-58), 75-95 ft lbs (1959-60) *CAUTION - Right and left coil springs are not interchangeable See "Spring Application" above* Tape spring insulator to top of spring *NOTE - Top of spring is identified by a flat coil which will allow insulator to seat squarely* While holding spring and insulator against pilot in frame crossmember, tilt spring so it will pilot over Tool J-6509 in lower control arm *NOTE - Tool J-6509 not required on 1960 springs* Rotate spring so end of bottom coil will index with edge of hole in control arm spring seat (coil should not cover any portion of hole) Position floor jack between spring seat and ball joint, then chain upper control arm to base of jack Raise lower control arm until ball joint is tight in steering knuckle, then install ball joint stud nut and tighten to 40 ft lbs and install cotter pin (tighten nut further as necessary to install cotter pin) *NOTE - A screwdriver slot is provided in ball joint stud to prevent stud turning when tightening nut.* Remove Tool J-6509 (if used) and install shock absorber Connect stabilizer to lower control arm and install wheel and tire Check front end alignment

BALL JOINTS: *NOTE - Upp r control arm ball joint is not replaceable. If ball j int is worn r damaged, complete upper control arm ass mbly must b install d.*

Removal (From Steering Knuckl): Raise front of car and place jack stands under lower control arm at a point between spring seal and ball joint Proceed as follows

Upper Ball Joint - Loosen ball joint stud nut a few turns, then install Removing Tool 6446 with hollow end of tool positioned over lower ball joint stud nut Rotate screw on tool and press ball joint loose from steering knuckle Remove tool and ball joint stud nut.

Lower Ball Joint - Loosen ball joint stud nut a few turns, then proceed as for upper ball joint (above), reversing tne tool position

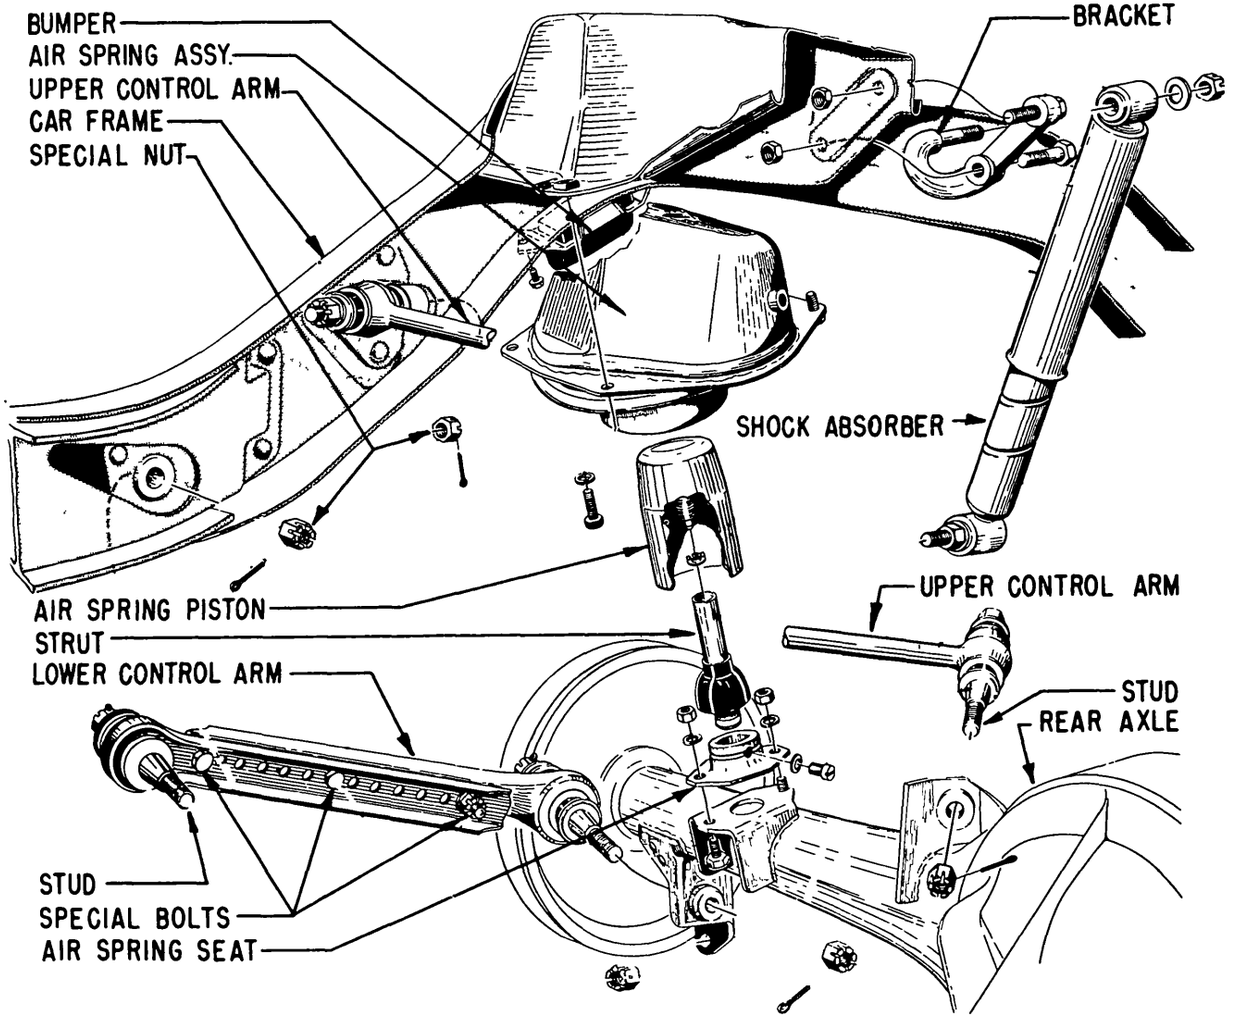
Lower Control Arm Ball Joint R placem nt (On Car): Raise front of car and support outer end of lower control arm with a floor stand, then remove wheel. Disconnect lower joint from steering knuckle and block steering knuckle, backing plate, and hub assembly away from lower control arm for accessibility. Drill a 5/16" hole 1¼" deep in rivet (through head), then use a 7/8" drill and drill deep enough to remove rivet head. Drive rivet out of control arm and ball joint. Repeat this procedure with other rivets. Install the new ball joint using the special bolts furnished. *NOTE - If riv ts cannot be driven out, then the bottom riv t h ods must also be drilled out. Be very careful not to l ngat holes in lower control arm wh n drilling riv ts.*

STEERING KNUCKLE: Rem val - Raise front of car and place jack stands under lower control arm at a point between lower spring seat and ball joint Remove wheel and drum assembly Remove brake backing plate without disconnecting brake hose Leave plain arm connected to tie rod end *(NOTE* - Support backing plate to avoid damage to brake hose) Remove cotter pin from upper ball joint, then remove upper and lower ball joints *(see "Ball Joints" above)*.

Installation: Connect lower ball joint to steering knuckle and tighten stud nut to 40 ft lbs and install cotter pin (tighten nut further as necessary to install cotter pin) Repeat this procedure with upper ball joint Install brake backing plate and plain arm to steering knuckle and tighten bolts to 55-60 ft lbs (1957) On 1958 and later cars, tighten steering knuckle-to-backing plate bolts to 75-80 ft lbs and plain arm-to-steering knuckle to 80-130 ft lbs Install wheel and drum assembly, then check wheel alignment

1958 OLDSMOBILE REAR SUSPENSION (AIR SUSPENSION CARS)

Oldsm bil (1958)



DESCRIPTION: Rear suspension linkage consists of two lower control arms connected between outer ends of rear axle housing and frame side rail, and two upper control arms connected between rear axle housing adjacent to differential carrier, and a bracket on frame side rail. A "track" bar or rear stabilizer is not used as the two upper control arms, being mounted at an angle prevent lateral movement of rear axle housing Lower control arms are adjustable for production to correctly position differential angle. Do not change adjustment of these arms.

►*LOWER CONTROL ARM REPLACEMENT CAUTION:* When replacing a damaged lower control arm, adjust new arm using the same corresponding holes before installing it in car

REMOVAL & INSTALLATION

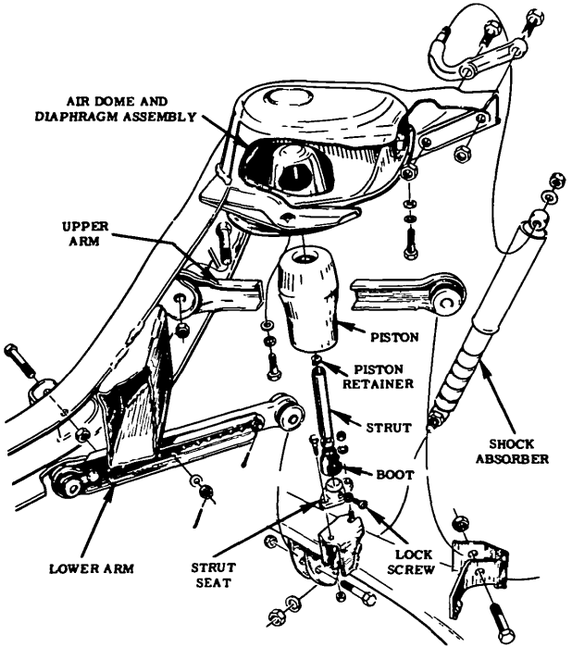
UPPER & LOWER CONTROL ARMS: Upper and lower control arms can be removed without disturbing air spring or leveling valve assemblies When installing upper or lower control arms, tighten attaching stud nuts to 80 ft lbs. minimum

AIR SPRINGS: *See "Oldsmobile Air Suspension".*

1958 OLDSMOBILE REAR SUSPENSION ASSEMBLY

1959 OLDSMOBILE REAR SUSPENSION (AIR SUSPENSION CARS)

Oldsmobile (1959)



DESCRIPTION: Rear suspension linkage consists of two lower control arms connected between outer ends of rear axle housing and frame side rail, and two upper control arms connected between rear axle housing adjacent to differential carrier, and a bracket on frame side rail. A "track" bar or rear stabilizer is not used as the two upper control arms, being mounted at an angle prevent lateral movement of rear axle housing. Lower control arms are adjustable for production to correctly position differential angle Do not change adjustment of these arms.

►*LOWER CONTROL ARM REPLACEMENT CAUTION:* When replacing a damaged lower control arm, adjust new arm using the same corresponding holes before installing it in car.

REMOVAL & INSTALLATION

UPPER & LOWER CONTROL ARMS: Upper and lower control arms can be removed without disturbing air spring or leveling valve assemblies. When installing upper or lower control arms, tighten attaching stud nuts to 80 ft lbs. minimum.

AIR SPRINGS: *See "Oldsmobile Air Suspension".*

1959 OLDSMOBILE REAR SUSPENSION ASSEMBLY

1954-56 PACKARD

Packard, All Series (1954)
Packard Series 5540 & 5560 Clipper (1955-56)

► *1955-56 SERIES 5560, 5660 (CLIPPER DELUXE) & SERIES 5580, 5680 (PACKARD) NOTE: "Torsion Level" Suspension used on these models. Front end alignment (as indicated below) is the same for both types of suspension.*

DESCRIPTION: Independent, parallelogram "Broad-Beam" type with new design Upper Support Arm and Direct Acting Shock Absorbers.

CHECKING & ADJUSTMENT: First check and adjust front wheel bearings, wheel and tire balance and run-out, and tire inflation. Place car on level floor and check following:

Tire Inflation (1954): As follows:
5413—30 lbs. front, 40 lbs. rear.
5426—26 lbs., front and rear.
5433—36 lbs., front and rear.
Others—(With Conventional Steering) 24 lbs. front, 20 lbs. rear. (With Power Steering) 22 lbs. front, 20 lbs. rear.

Tire Inflation (1955): 24 lbs., front and rear. *NOTE*—If more than four passengers, inflate to 26 lbs., front and rear.

Kingpin Inclination: (5413, 5433) 2°30' (Other Models) 5°50'.
Caster: (5413, 5433) 2°±½°. (Other Models) 1°±½°.

Adjustment—Remove lubrication fitting in bushing at forward end of upper support arm outer pivot pin, use Allen wrench inserted through this hole to turn the pivot pin in **complete revolutions only.**

►***CAUTION—Pin is eccentric and will disturb camber setting unless it is rotated in full turns only.***

Camber: 0° plus ¾°, minus ¼°.

Adjustment—Same as for Caster (above) except that eccentric pin should be turned **not more than one-half revolution** from point where correct caster setting secured. Entire range of adjustment is secured in ½ turn of the pin.

►***CAUTION—Caster will be disturbed if pin turned more than one-half revolution.***

Toe-In: 0", plus 1/16", minus 0" (0" to 1/16" range).

Adjustment—Loosen clamp bolts at each end of adjusting sleeve at outer end of each tie rod, turn adjusting sleeves on **both tie rods equally.**

Toe-Out on Turns: With outer wheel at 20°, inner wheel should be 23¾°. Not adjustable.

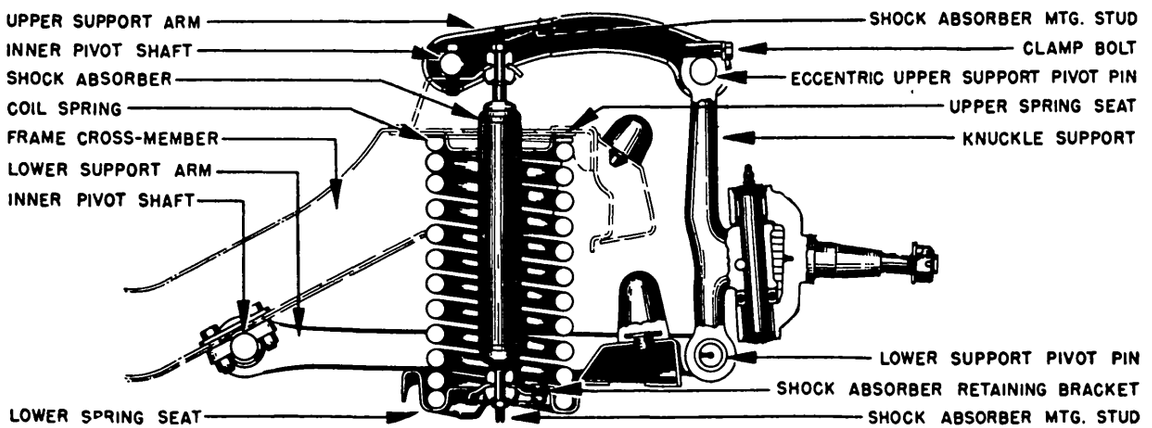
SHOCK ABSORBER REPLACEMENT: Raise car until there is sufficient clearance to permit shock absorber to be removed through hole in bottom of lower support arm. Using an offset screw driver, insert the tool in slot of shock absorber extension. While holding top of shock absorber extension, remove shock absorber nut, washer, grommet. From underneath lower support arm, remove nuts holding shock absorber retainer bracket to bottom of lower spring seat, and remove shock absorber.

Installation—Reverse the removal procedure. Tighten shock absorber stud nut to 12-18 ft. lbs., and the lower retaining bracket nuts to 15-18 ft. lbs.

►***CAUTION—Make certain that rubber grommets and cup-shaped washers correctly assembled on upper and lower mounting studs.***

COIL SPRING REPLACEMENT: Raise front end of car and place a jack stand under frame side rail to rear of suspension cross-member. Remove stabilizer to frame horn attaching nuts. Disconnect stabilizer end from lower support arm and remove shock absorber. Remove the front wheel and place a jack under outer end of lower support arm and raise just enough to relieve pressure on lower support pivot pin. Remove the pivot pin nut and screw out the pivot pin. Lower jack slowly to allow support arm to go down, then remove coil spring.

Installation—Position spring in lower support arm with the flattened end of spring upward. Place jack under lower support arm near outer end, and raise jack until holes in outer end of support arm are in line with holes in knuckle vertical support lower bushing. Centralize knuckle support in support arm (there should be approximately ⅛" clearance between inner face of arm and each bushing). Install lower pivot pin in through the front of support arm and tighten to 85 to 95 ft. lbs. torque. Position end of front stabilizer rod in lower support arm. Insert "ears" of the stabilizer attaching clips in holes of support arm, and spring the clip over bottom edge with tool J-4654. Install shock absorber through bottom frame front cross-member opening with the extension extending out through top of cross-member. Slip the rubber grommet and washer over top end of shock absorber and install the nut. Tighten retaining nut to 12-18 ft. lbs. torque. Install front wheel, remove stand from under car and lower car to floor.



►***SPRING INSTALLATION CAUTION***—**Flattened end of spring must be upward and end of lower coil must be seated in recess in lower spring seat so as to cover the drain hole in the spring seat.**

UPPER SUPPORT ARM REPLACEMENT: Support front end on jack placed under lower support arm, remove wheel and tire assembly. Unscrew front and rear bushings on outer pivot pin. Remove clamp bolt from upper end of knuckle support, unscrew pivot pin from support. Remove two mounting bolts from support arm inner shaft, lift support arm assembly off. To remove shaft from support arm, unscrew bushing from arm at each end of shaft.

►***INSTALLATION CAUTION***—When installing inner pivot shaft bushings in arm, use Spreader Tool J-3957 to maintain arm alignment while screwing bushings in. After installing support arm on frame, hold knuckle support centered in arm while screwing bushings in arm and on pivot pin. Make certain rubber seals installed at inner end of each bushing.

LOWER SUPPORT ARM REPLACEMENT: Remove shock absorber and coil spring (see directions above). Remove nut and lockwasher from rear end of lower pivot bolt at outer end of arm, unscrew bolt from knuckle support and support arm, lift support arm assembly off. Remove pivot shaft by unscrewing bushing from arm at each end of shaft.

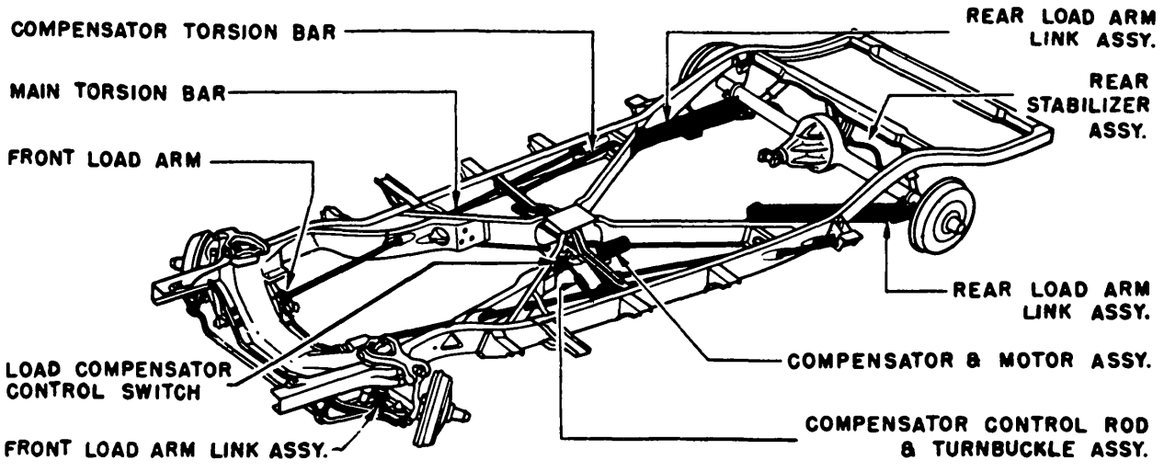
►***INSTALLATION CAUTION***—When installing pivot shaft bushings in arm, use Spreader Tool J-1052 to maintain support alignment. Install rubber seal at inner end of each bushing.

PACKARD FRONT SUSPENSION

PACKARD "TORSION LEVEL" SUSPENSION

5560 S ri s (Clipp r D Luxe) (1955)
5580 S ri s (Packard) (1955)
5660 S ri s (Clipper Custom) (1956)
5670 S ri s (Packard Ex cutive) (1956)
5680, 5688 S ri s (Packard) (1956)

► CAUTIONS



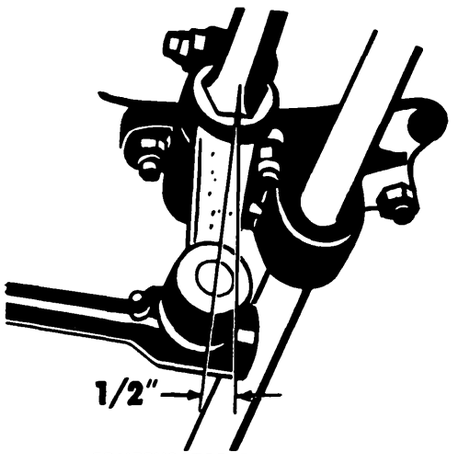
►*FRONT END ALIGNMENT NOTE: Alignment specifi- cations or th same for "Conventional" & "Torsion L v l" type suspensions. See "Packard (Conventional)" Front Susp nsi n for data.*

►*SERVICING CAUTION: The "On-Off" Switch located below th instrument panel must be in the "OFF" positi n when cars "jacked-up" for service operations. DO NOT plac jack r hoist under rear load arms as thes may b com disc nnected.*

► *1956 RAISING &LOWERING OF CAR CAUTION (To Perform Servic Functions on "Torsion Level" Suspension):* Due to complete change in wiring and new type limit switches method of raising and lowering car by grounding at each side of limit switches or the "A" and "B" terminals of the control switch can no longer be used. To raise or lower car with later type switches proceed as follows: Remove four small screws from small cover plate on bottom of control switch. Lower plate slightly to expose wire terminals in control switch. The two outer terminals of the center group of three can be grounded with a screwdriver or jumper wire to raise or lower the car. *CAUTION* - Do not raise or lower the car by grounding wires on solenoids as limit switches will be by-passed and compensator gears may be damaged.

► *FUSE NOTE:* Control Circuit Fuse (AGW-7½ amps.) and Compensator Motor Feed Fuse (AGC-30 amps.) are located under hood on left side of engine compartment.

DESCRIPTION: Two long, torsionally flexible bars (running generally fore and aft along frame side rails) have hexagonal ends which fit into load arms (one at each end of each bar) which are hexagonally broached at one end. Front load arms pivot on anti-friction needle type bearings on brackets mounted on frame front cross member. Rear load arms also pivot on needle type bearings in brackets attached to frame side rails. Front arms are loaded against anti-friction links which seat in front suspension lower support arms. Rear arms are loaded against stirrup type links suspended from driving torque arms. Arms on each side are installed in such a manner that loaded ends are pointing in opposite directions (loaded end of front arm is pointing away from center of car whereas loaded end of rear arm is pointing toward center of car). Initial loading of arms is accomplished by "winding up" or twisting torsion bar during its assembly in chassis. Operating in conjunction with Torsion Level Suspension is a levelizing or compensating mechanism which automatically keeps car level and approximately at its designed height regardless of load.



PACKARD TORSION LEVEL SUSPENSION ASSEMBLY

Front Suspension: Except for minor design changes, the independent parallelogram type front suspension remains unchanged. Major change is elimination of coil springs.

Rear Suspension: Thrust of rear axle to frame, in order to move car, is accomplished by two driving torque arms, one at each side of frame, attached to frame at forward end by rubber cored bushings. Arms are also insulated by rubber at points of attachment to rear axle housing, permitting free movement of axle. Transverse or side-to-side movement of rear axle is controlled by two waved stabilizer bars which permit true vertical movement of rear axle. Rubber grommets, at ends of bars, insulate wheel shocks from frame.

Compensator: Basically, compensator consists of torsion bars approximately four feet long, connected by means of levers and links to a two-way motor with reduction gearing. Forward end of compensator bars rotate in bearings attached to frame. Hexagonal rear end of bars fit into rear load arms in milled hexagonal openings adjacent to main torsion bar openings. Bar type links are connected to the compensator gear box at their inner ends and, at their outer ends, to levers attached to front end of compensator bars. Six switches are used in compensator electrical system to control its operation. Control switch assembly is attached to frame forward of compensator motor. A lever in switch assembly is linked to a lever clamped to left main torsion bar near center of bar.

OPERATION: Torsion Level Suspension—Vertical wheel movement causes link end of load arms to move vertically. Vertical movement of either arm increases or decreases the amount of twist in the torsion bar which in turn transmits this twisting force to the arm on the opposite end of the bar and the load on the link end of this arm then is increased or decreased. The force beapplied to move front load arm is in an upward direction. The force opposing the movement of the rear load arm may be thought of as being in an upward direction. Therefore, the arms are being loaded against each other with the bar absorbing the torsional load. In addition to absorbing the torsional stresses created by road irregularities the load arms and torsion bars also

COMPENSATOR BAR "NO LOAD" POSITION

function in a manner which raises or lowers the car, front and rear, on the side where road irregularity is encountered.

Compensator: With front and rear of car equally loaded, center section of main torsion bar has no rotation du to equal twisting forces being applied at each end of bar. When loading at either end of car is increased or decreased, center section of main torsion bar will rotate causing control switch to make contact and "make" and "break" circuit to compensator motor. This causes connecting links to move inward or outward to rotate compensator bars. The bars, in turn, cause rear load arms to pivot and either raise or lower rear end f car to make it level with front end. Thus, regardless of

CONTINUED ON NEXT PA E

PACKARD "TORSION LEVEL" SUSPENSION (Cont.)

weight distribution, car remains level to road, front and rear, with very little change in car height. It should be remembered that compensator functions only when loading of car is changed and does not function to compensate for road irregularities. *NOTE*–Control switch has approximately a seven second delayed action to prevent motor from operating each time wheels pass over an irregularity in road.

Switches–Six switches used to control compensator as follows:

"On-Off" Switch–Located below instrument panel to left of steering column.

►*CAUTION: This switch is normally in "ON" position and is moved to "OFF" position to prevent compensator from operating when car is raised for service operations.*

Stop Light Switch–A three terminal two-way stop light switch is used to prevent compensator operation during brake application.

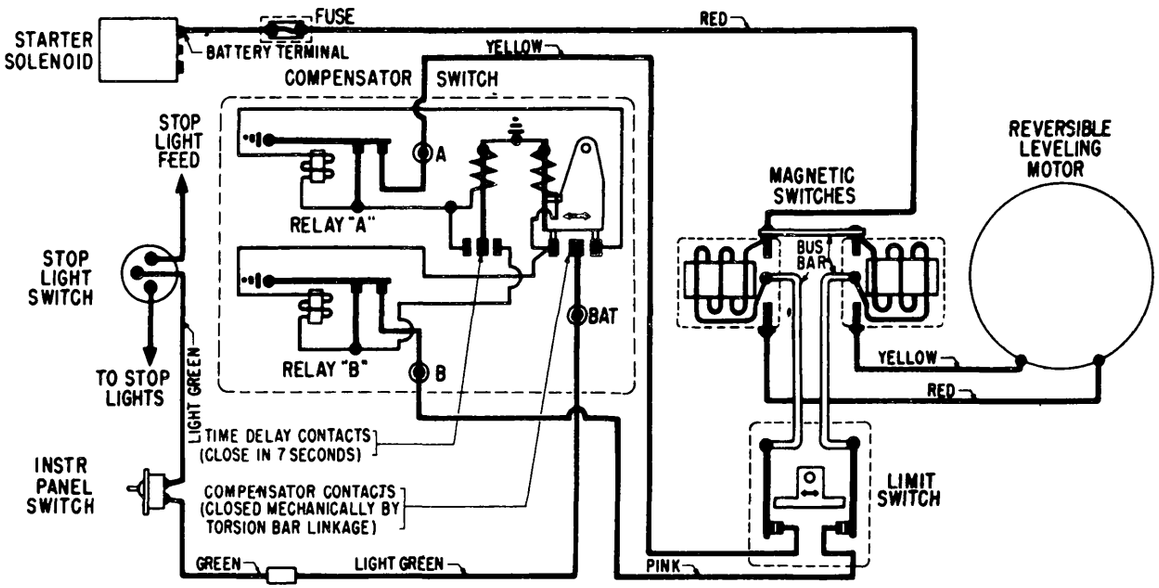
Control Switch–Used to energize compensator motor when car load is increased or decreased.

Limit Switch–Employed to permit compensator motor to operate only within a predetermined range in accordance with load changes in car.

Solenoid Switches–Two used to complete electrical circuit to compensator motor, one for each direction of rotation of the motor.

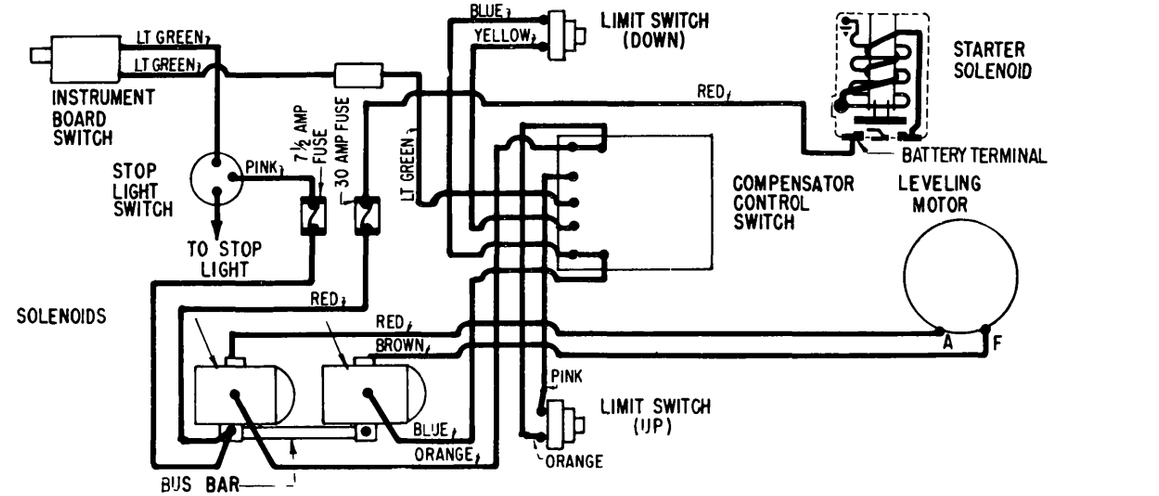
ADJUSTMENT: Compensator Linkage–Set car on its wheels. If rear end of car is too high, shorten compensator switch turnbuckle. If rear end too low, lengthen link.

LUBRICATION: Incorporates ten lubrication points which should be lubricated every 1000 miles with pressure gun grease. Whenever torsion bars are replaced or unloaded for other service operations, link seats should be lubricated with a special grease.



►*SERVICING CAUTION: Car should never be jacked in rear with jack or hoist under rear load arms as the rear load arm link may become disconnected.*

TORSION BAR REMOVAL: Position car on hoist and move the "on-off" switch, located under instrument panel to left of steering column, to the "off" position. Raise car and remove rear wheel on side from which torsion bar is to be removed. Proceed as follows:



1)–If a frame contact type hoist is used, place the high-jacks under rear axle housing and under the outer ends of front lower supports. On other type hoists, place the high-jacks at all four corners, front and rear, then extend jacks so that pads contact the frame.

2)–Note position of compensator bar lever in illustration, as this is the position in which no load is being transmitted through the bar. Bar should be just off vertical toward the center. Move levers as necessary by grounding a terminal at the limit switch. Grounding rear terminal will move lever outward, front terminal will move lever inward.

3)–Remove nuts retaining rubber guide bearing and compensator retainer bracket to cross member and remove these parts. (*NOTE–If I ft t nsi n bar is being r m v d, d tach c mpensat r link fr m c mp nsator link from c mpensator bar).*

1955 TORSION LEVEL SUSPENSION CONTROL WIRING DIAGRAM

1956 TORSION LEVEL SUSPENSION CONTROL WIRING DIAGRAM

4)–Loosen rear load arm clamping bolt using an 11/16" socket and offset handle. Tap compensator bar forward and out of load arm. Slightly raise or lower rear hoist lift if required to centralize hex in arm with hole in bracket.

5)–Attach Load Arm Centering Tool J-6045 with piloting shoulder of tool in hole in bracket and opposite end of tool installed in elongated hole above compensating bar hole in bracket, tighten the locknut.

6)–Attach clamping detail of Torsion Bar Loading and Unloading Tool J-5954 at inner end of load arm and then install jack attachment to clamping detail. The hole in frame for attaching jack attachment is in line with the front of the brake drum. Operate jack to move inner end of load arm upward far enough to centralize the pivot bolt in bracket (pin is located between load bar and compensator bar holes in bracket). Use a brass drift and tap pivot bolt out of bracket.

7)–Tighten jack to move inner end of arm upward to clear load arm link and then move load arm link inward. Place a four inch block between rear axle case and bottom of frame "kick-up". While holding link inward, reverse tool ratchet and lower inner end of arm to relieve load on bar.

CONTINUED ON NEXT PAGE

PACKARD "TORSION LEVEL" SUSPENSION (C nt.)

8)–Remove clamp from load lever and attach Removing Tool J-6046 to bar forward of bracket. Strike tool with a hammer and drive bar toward rear. Remove tool and push bar out toward rear.

TORSION BAR INSTALLATION: *CAUTION–An arrow is stamp d in nd of bar denoting direction in which bar must be "wound up". The three digits stamped in end of bar ar th last three digits of bar part number.*

1)–Insert rear load arm in bracket and feed bar through bracket and load arm (if left bar being installed, feed bar through compensator link also), and into front load arm making sure that front load arm link is in correct position and that rear load arm is nearly vertical with clamping detail of Torsion Bar Loading and Unloading Tool J-5954, and Centering Tool J-6045 in place. Distance from rear end of torsion bar in load arm to rear face of bracket should be ¾" with rear load arm centered in bracket.

2)–Place special lubricant in seat in load arm link and connect tool jack to clamp on load arm. Operate jack and draw load arm up into position where pivot hole in arm lines up with pivot hole in bracket, and then insert pivot pin.

3)–Continue to draw upward while holding link inward until link can be swung outward under arm, then back off jack to seat arm.

4)–Position compensator bar in rear load arm and attach bearing at front of arm to frame (seal between bearing and lever should not be squeezed together but should contact both the bearing and lever). Tighten clamp nut in rear load arm. Remove clamp, jack, and centering tools.

5)–If left torsion bar replaced, attach compensator motor linkage so that rear edge of clamp lever is ¾"from front edge of rubber guide bearing retainer. Adjust compensator linkage (see above).

1954-57 PONTIAC

All S ri s (1954-57)

►CHANGES, CAUTIONS, CORRECTIONS

►*PIVOT PIN INSTALLATION NOTE:* Effective 1956 production, upper and lower pivot pins are installed from rear **on right hand side.** This makes it necessary to lubricate pivot pins on right hand side from rear.

►*REAR SPRING ASSEMBLY CAUTION (1956):* Early production new rear spring assembly, with Butyl rubber liners, was used on Catalinas, sedans, and convertibles **at P ntiac Ass mbly Plant only.** They are not being released for service. Rear spring U-Bolt torque has been reduced to 45-55 ft. lbs. and it is especially important that these torque limits be observed on springs with Butyl liners.

DESCRIPTION: Independent linked parallelogram with direct acting shock absorbers mounted within coil springs.

CHECKING & ADJUSTING: Check entire front end for wear and excessive play, inflate tires to correct pressures, check steering gear adjustment, wheel bearing adjustment, wheel & tire balance and run-out (run-out should not exceed 1/8"). With car on level floor, jounce both ends (see Leveling instructions) and check frame height. Check and adjust front suspension assembly in following order:

L veling Fram : Jounce car at the rear and then at the front and allow car to settle to normal operating position. Measure frame height.

Fram H ight–Measure vertical distance from underside of frame side rail to top of lower control arm on each side of car. Distance should be the same on both sides of car. Unequal heights indicate sagged springs. See Spring Data below.

Tir Inflati n Pr ssur : With tires COLD inflate to following pressures:

7.10 x 15 – 24 lbs.. Front & Rear.
7.60 x 15 – 22 lbs., Front 20 lbs., Rear.
7.10 x 15 (Sta. Wgn.)–28 lbs., Front. 30 lbs., Rear.
7.60 x 15 (Sta. Wgn.) 26 lbs. front and rear.
7.60 x 15 (Safari Sta. Wgn.) 24 lbs. front and rear.
7.60 x 16 (Air Cond.) 24 lbs. front and rear.
7.50 x 14 22 lbs. front and rear.
8.00 x 14 22 lbs. front and rear.
8.00 x 14 (Air Cond.) 24 lbs. front, 22 lbs. rear.
8.50 x 14 (Exc. Safari & Air Cond.) 22 lbs. front and rear.
8.50 x 14 (Star Chief Safari) 22 lbs. front and rear.
8.50 x 14 (Chieftain & Super Chief Safari) 24 lbs. front and rear.
8.50 x 14 (Air Cond.) 22 lbs. front, 20 lbs. rear.

Kingpin Inclination: 4½° at ½° camber (1954). 1°20' (1955-57).

Caster: 0°±½° (1954). Neg. 1°±½° (1955-57).

Adjustment–Loosen clamp bolt in upper end of knuckle support, use special wrench J-5343 to engage hexagonal head of bushing on pivot bolt in upper end of support, adjust caster by turning bushing in **complete turns only to avoid disturbing camber.**

►*CAUTION:* Clearance must be maintained between ends of bushing and control arm throughout suspension unit travel. Check for binding when adjusting caster.

Camber: Pos. ½°±½°.

Adjustment–Same as for Caster (above) except that eccentric bushing should be turned not more than ½ revolution from point where correct caster secured, (entire range of adjustment secured in ½ revolution of bushing).

Toe-In: 0" to 1/16" measured 9" from floor.

Adjustment–Loosen clamp bolts at each end of adjusting sleeve at outer end of each tie rod, turn adjusting sleeves **on both rods equally.**

Toe-Out on Turns: With inner wheel turned 20°, outer wheel should be 18-19°.

SHOCK ABSORBER REPLACEMENT: *Not necessary to disturb front suspension assembly.* Shocks remove from above upper control arm. Raise car so weight is off front wheels. Remove nut from bottom stud on shock absorber (hold shock with water pump pliers). Remove grommet and retainer and compress shock as far as possible by pushing lower section up. Remove two nuts holding shock bracket to frame (on left side of car, remove bracket from shock first). Shock can be removed through hole in frame. Install shock absorber with shock compressed, into spring, then extend shock so nuts and grommet can be installed on lower end.

UPPER CONTROL ARM REPLACEMENT: *Upper pivot pin and cc ntric bushing can be replaced without r - moving control arm from car.*

Removal: Support car with jack placed under lower control arm and remove wheel. Remove shock absorber and upper bracket (see Shock Absorber). Take off nut on rear end of upper pivot pin, unscrew threaded pivot pin from knuckle support and control arm (CAUTION–Wire knuckle support to frame to prevent damage to brake hose). Loosen clamp bolt in knuckle support, and unscrew eccentric bushing. Take out two bolts mounting inner control arm shaft to frame (the nuts can be reached through access hole in front cross member).

Pivot Shaft Installation: Use spreader tool J-5324 to expand inner end of control arm to 6 9/16" (measured between inner faces of arm). Place pivot shaft with new rubber seals in position in control arm. After lubricating pivot shaft threads with chassis grease, start bushing on pivot shaft and into arm at same time. Tighten so bushing flange is firmly seated against control arm (326-380 ft. lbs. torque). Center pivot shaft in control arm and start other bushing being sure threads index so there is no bind. Tighten in same manner as other bushing. Remove spreader tool. Check to see that distance between inner faces of control arm is 6 9/16". Rotate shaft to centralize it so that bolt hole at each end of shaft is an equal distance from arm. *NOTE*–Frictional drag of shaft in bushings should not exceed 12 in. lbs.

Upper Pivot Pin & Eccentric Bushing Installation: Install new rubber seal on inner face of control arm eyes (slip end of rubber seal over boss, double other end back to allow clearance for assembly). Install eccentric bushing in knuckle support. Hold knuckle support centered in upper control arm, thread pivot pin through control arm and bushing (coat pin threads with chassis lubricant, see that one lockwasher placed under head of pin) and tighten pin against arm with 50-55 ft. lbs. torque, then install pivot pin nut and lockwasher and tighten to 50-55 ft. lbs. torque. Turn pivot pin seals back to cover pivot pin threads.

Control Arm Installation: Position upper control arm on frame cross member and install bolts and nuts. Tighten nuts to 80-85 ft. lbs. torque (nuts are self-locking and must be tightened with an extension inserted through hole in front cross member).

CONTINUED ON NEXT PAGE

1954-57 PONTIAC (C nt.)

LOWER CONTROL ARM REPLACEMENT: *Low r pivot pin and bushing can be replaced without removing control arm from car.*

Removal: Remove shock absorber (see Shock Absorber data) then proceed as with Front Spring Removal. After spring removed , remove nuts and lock washers holding lower control arm shaft to frame cross member and remove control arm and shaft assembly. Remove shaft from control arm by removing front and rear threaded bushings from shaft and control arm.

Pivot Shaft Installation: Use Spreader Tool J-1052 to expand inner end of control arm to 11½" (measured from inner faces of arm). Position pivot shaft (with new rubber seals) in control arm, lubricate shaft threads with chassis lubricant, start one bushing on shaft and into threads in arm at the same time, tightening bushing to 385-455 ft. lbs. torque and firmly seated against arm. Center shaft in arm (distance from shaft mounting hole centers to inner face of arm should be 1½"±3/64" at each end). Install second bushing similarly. Remove tool and check control arm dimension (11½"±3/32" between inner faces of arm at pivot shaft), recheck pivot shaft position and centralize it by rotating shaft if necessary.

Lower Pivot Pin & Bushing Installation: Install new bushing in lower end of knuckle support and tighten to 250 ft. lbs.(CAUTION—Bushings must be firmly tightened and bushing shoulder must be seated against support). Position new rubber seal on each end of bushing, hold knuckle support centered in lower control arm, thread pivot pin through control arm and bushing (coat pin threads with chassis lubricant, see that one lock washer placed under head of pin) and tighten pin against arm with 50-55 ft. lbs. torque, install pivot pin nut and lockwasher, tighten to 50-55 ft. lbs. torque. Check knuckle support for centralized position (distance from end of bushing to inner face of control arm must be equal within one thread or 1/8" at each end of bushing).

KNUCKLE SUPPORT REMOVAL (For Kingpin Bushing Replacement): Remove brake backing plate and hang plate up out of way (not necessary to disconnect brake line). Remove upper and lower pivot pins (see Upper and Lower Control Arm data above).

SPRINGS: Upper end of springs are flattened and lower end must be fitted in recess in lower seat. Color marks located on outside surface of spring center coil

COIL SPRING REPLACEMENT: Raise front of car until wheels are 10" off floor, then place jack stands under frame side rails at a point forward of front door hinge pillar. Place another jack stand under lower control arm of spring which is not being removed. Place a floor jack under lower control arm spring seat from which spring is to be removed and raise jack until it touches spring seat. Remove wheel, and then remove shock absorber (see above). Disconnect lower end of stabilizer link at lower control arm. Remove lower pivot pin from bushing, then slowly lower jack until coil spring is fully extended, then remove spring. To install spring, place jack under spring seat, then place coil spring in seat on lower control arm with end of coil at bottom of spring indexing with hole in spring seat *(NOTE* -Top of spring is identified by a flat surface on coil). Raise jack gradually until lower arm is in position. Complete installation by reversing removal procedure

►*FRONT SWAY BAR INSTALLATION CAUTION:* Sway bar must be installed with the proper side up or grommets may be damaged due to improper contact with eye in bar.

1958-60 PONTIAC FRONT SUSPENSION

Pontiac (1958-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*LOWER BALL JOINT LOOSENESS NOTE:* A slight looseness in the lower ball joint, with weight of car off the wheels, is normal. If movement of wheel at outer circumference is greater than ¼", excessive wear in wheel bearing, ball joints, or both is indicated.

►*STABILIZER BAR REPLACEMENT CAUTION:* Different stabilizer bar is used on cars with air suspension. The shaft for cars with coil springs has a diameter of 3/4" (13/16" on air suspension cars). Do not interchange.

►*FRONT SUSPENSION "CRACKING" NOISE CORRECTION:* This condition may be caused by rough surfaces on wheel stops and is noticeable when wheels are turned full right or full left. Correct by smoothing the forged stop pad on steering arm. Do not remove an excessive amount of material. Lubricate wheel stops every 2,000 miles with Lubriplate.

DESCRIPTION: "Ball-joint" type suspension with spherical ball joints connecting upper and lower control arms to steering knuckle. Coil springs are mounted between lower control arm and frame front crossmember with direct acting shock absorbers mounted within the springs. On 1958 models, lower control arm inner end is pivoted on a shaft which is bolted to frame crossmember. Threaded steel bushings connect lower control arm to pivot shaft. On 1959-60 models, pressed-in rubber bushings at inner end of lower control arm are bolted to brackets on crossmember by special 9/16" bolts.

ADJUSTMENT

CHECKING & ADJUSTING: Before checking or adjusting front wheel alignment, inflate tires to correct pressure, check adjustment of front wheel bearings and check steering gear and linkage for excessive looseness see *"Lower Ball Joint Looseness Note"* above.

►***NOTE: Check and adjust camber and cast r with car at curb h ight. On 1960 mod ls, install sp cial front and rear spac rs (see "1960 Riding H ight" below).***

CONTINUED ON NEXT PAGE

1958-60 PONTIAC FRONT SUSPENSION (C ntinu d)

Tir Inflation: (8.00 x 14) - 22 lbs , front & rear(exc Safari & Air Cond Cars) (8.50 x 14) - 20 lbs , front and rear (exc Safari & Air Cond Cars) (8.50 x 14) - 22 lbs , front, 20 lbs , rear (Safari and Air Cond Cars) Above pressures are with tires cold

Steering Axis Inclination: 4°50' at 0° Camber Not adjustable

Cast r: Neg. ½°±½° (1958). Neg. 1½°±½° (1959-60). *See "Shimming Procedur s" b low.*

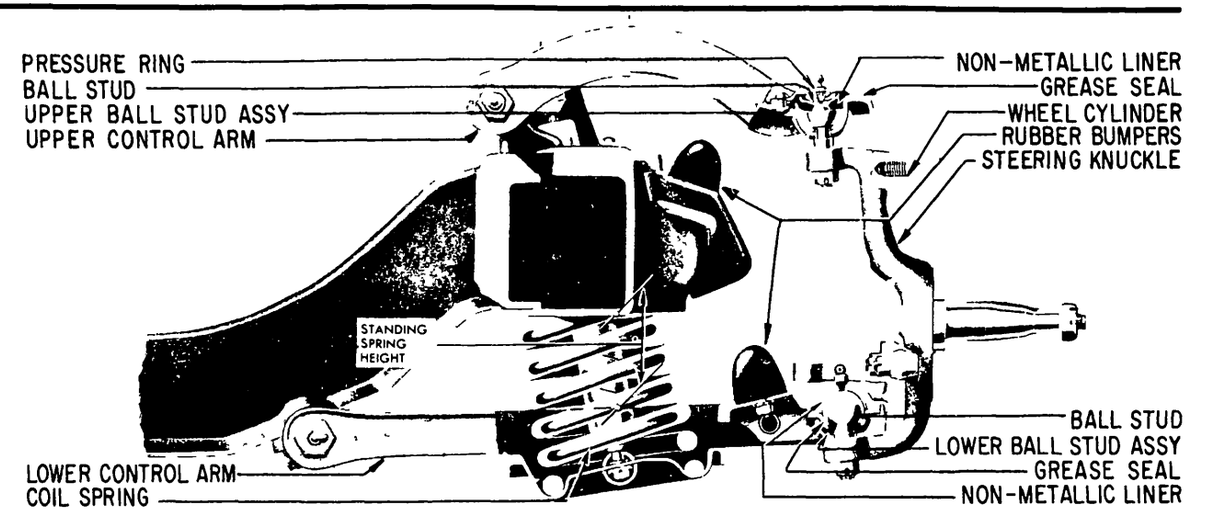
Camber: Pos ½°±½°. *See "Shimming Procedure" below*

T -In: 0-1/16", with trammel 9" above floor

T -Out n Turns: With right wheel turned 20° to right from straight ahead position, left wheel should be turned 18° to 19°

SHIMMING PROCEDURE: Adjustments are made by placing shims between upper pivot shaft and frame Caster and Camber adjustments can be made at the same time To **decreas** positive caster, add shims to front bolt To **incr as** positive caster, remove shims from front bolt To **incr ase** camber, add shims to both front and rear bolts *NOTE* - By adding or subtracting an equal amount of shims from front and rear bolts, camber will be changed without affecting caster

Shim Selection Table



Shim Siz	Caster Change (Shim at fr nt bolt)	Camber Change (Shim at both bolts)
030"	23'	1/6°
060"	45'	1/3°
164"	2° 7'	1°

REMOVAL & INSTALLATION

►*FRONT COIL SPRING REMOVAL & INSTALLATION NOTE: Tool J-7592-01 can be used to compress spring for removal and installation. If used on 1959-60 models, inn r nd of lower control arm can be disconnected from frame front crossmember by removing two special 9/16" bolts which pivot lower control arm on brackets.*

FRONT COIL SPRING: R moval - Raise front of car with jack until wheels are about 10" off floor and place car stands under frame side members on each side of car forward of radiator Place floor jack under outer edge of lower control arm spring seat from which spring is to be removed and raise jack until it touches spring seat Remove wheel assembly then remove shock absorber (see below) Disconnect stabilizer link at lower control arm and steering arm at tie rod Remove lower ball joint stud nut Using Tool J-6627 press lower ball stud from steering knuckle Tilt steering knuckle out to clear control arm and lower jack until spring is fully extended and remove spring

Installation: Place jack pad under spring seat and place spring on spring seat with flat coil end toward top Raise jack gradually checking to see that spring is positioned correctly Raise until lower arm clears steering knuckle, then lower jack slightly while guiding ball stud into knuckle Install nut and cotter pin on stud and install shock absorber Connect stabilizer link and steering linkage. On 1959-60 models, if inner ends of lower control arm were disconnected from crossmember, tighten special 9/16" bolts attaching arm to frame crossmember to 150-175 ft. lbs.

① — Without Air Conditioning ③ — Without high rate springs.
② — With Air Conditioning. ④ — With high rate springs.

►*COIL SPRING IDENTIFICATION NOTE: Springs are marked with paint as follows:* Yellow & Blue (532886); Yellow & Brown (534359); Yellow & White (532890); Yellow & Dark Green (532888); Yellow & Pale Green (534358); Yellow & Red (532889); Yellow & Orange (532887); Yellow & Grey (532891).

Riding Height (1960 Models): 3¾"-4" (3 15/16"), measured from top of lower control arm to underside of frame at a point directly behind centerline of spring. *NOTE - For front wheel alignment adjusting, a spacer (steel bar stock ½" x ½" square) cut to above length, may be used between lower control arm and crossmember at at centerline of spring to position car at correct riding height.*

SHOCK ABSORBERS: Removal - Raise front of car so weight is fully off front wheels, then remove nuts, retainer, and grommet attaching upper end of shock absorber to frame bracket *NOTE - Shock absorber piston rod must not turn while loosening nut. Use pliers or wrench to hold top of shock mounting while removing nuts* Remove bolts retaining shock at lower end and remove shock absorber

Installation: Reverse removal procedure

LOWER CONTROL ARM (1958 COIL SPRING CARS): Removal - Remove front coil spring, then remove nuts and lockwashers holding lower control arm shaft to frame crossmember. Remove shaft from arm by removing front and rear threaded bushings from shaft and control arm.

Installation: Reverse removal procedure and tighten control arm shaft-to-frame nuts to 70-85 ft lbs If a new lower control arm is being installed, it will be necessary to cut a thread in extruded portion of arm for the bushing as follows Place Tool J-1052 in position and expand arms until distance between inner faces of arms is 11½" Place shaft with rubber seals in position in control arm, then lubricate shaft threads with a 25% graphite lubricant and start bushing on pivot shaft and into arm at the same time Tighten until bushing flange is firmly seated against metal of control arm

CONTINUED ON NEXT PAGE

1958-60 PONTIAC FRONT SUSPENSION (C nt.)

(385-455 ft. lbs. will be required). Center shaft in control arm and install other bushing being sure threads index so there is no bind. Tighten until bushing flange is firmly seated against metal of control arm, then remove Tool J-1052. Check to see that distance between inner faces of shaft ends of control arm is 11½"±3/64". Also check to see that distances from center of pivot shaft bolt holes to inside faces of arm are equal at each end. Equalize if necessary.

LOWER CONTROL ARM (1958 AIR SUSPENSION CARS):

Removal - Raise front of car so wheels are off floor, then remove wheel. Disconnect pipe at spring to relieve pressure, then remove locknut at upper end of control link and lift end of stabilizer shaft from link. Disconnect ball stud from steering knuckle *(see "Coil Springs" above)*, then remove air spring piston to lower control arm attaching bolt. Remove bolts holding lower control arm to frame crossmember and remove arm (air spring will hang free in air diaphragm). Remove rubber bushing retainer from each end of control arm pivot shaft. Thread bolt into one end of control arm pivot shaft and rest opposite end of arm on bed of press, then press shaft through upper bushing (bolting pad on shaft will force lower bushing from control arm).

Installation: Place Spreader, Tool J-1052 in position in arm and tighten nut. Distance between inner faces of control arm at bushing bosses should be 11½". Position shaft in control arm so shaft bolting pads are approximately 20° above alignment with arm. Using bushing replacer cups, J-7166 press bushings onto shaft and into control arm. Remove bushing installing tools. Attach lower control arm shaft to frame crossmember and tighten bolts to 70-75 ft. lbs. Swing arm into position aligning air spring attaching bolt hole with hole in arm. Guide ball stud through steering knuckle and secure with nut. Tighten nut to 60-95 ft. lbs. and install cotter pin. Tap ends of control arm to insure no twist exists in rubber bushings, then install bushing retainers and bolts. Tighten bolts to 50-70 ft. lbs. Attach air spring to control arm and tighten bolt to 50-70 ft. lbs. To complete installation, reverse removal procedure. Tighten stabilizer shaft-to-link inner nut to 10-25 ft. lbs., and outer nut to 60-120 ft. lbs.

LOWER CONTROL ARM (1959-60 COIL SPRING CARS):

Removal - Remove coil spring (see above), then disconnect inner end of lower control arm by removing nuts and withdrawing two special 9/16" diameter bolts.

Lower Control Arm Bushing Replacement: With lower control arm removed, rest arm on Remover Tool J-7022-1 and place Spacer Tool J-7022-7 around bushing, then with Sleeve J-7022-3 between control arm and arbor of press, press bushing from arm. Remove other bushing in same manner. To install bushing, rest arm on Sleeve J-7022-3 and place Spacer Tool J-7022-7 between arm flanges at bushing position. Start bushing in arm, then press it into position with an arbor press and Tool J-7022-2.

Installation: Reverse removal procedure and tighten lower control arm to frame bolts to 150-175 ft. lbs. Tighten lower ball stud nut to 60-95 ft. lbs.

Installation: Reverse removal procedure and tighten control arm shaft-to-frame bolts to 80-95 ft. lbs. If a new control arm is being installed, proceed as follows: Place Tool J-7167 in position between arms and expand until distance between inner faces of arms is 8 31/32". Place pivot shaft with new rubber seals in position in control arm. Lubricate pivot shaft threads with chassis lubricant, then start bushing on pivot shaft and into arm at the same time. Tighten so bushing flange is firmly seated against control arm (326-380 ft. lbs. will be required). Center pivot shaft in arm and install other bushing being sure threads index so there is no bind, then tighten in same manner as for first bushing. Check to see that distance between inner faces of shaft ends is 8 31/32"±1/32" and that shaft is centered between arms.

LOWER CONTROL ARM (1959 AIR SPRING CARS): *NOTE - Removal and installation procedures are the same as for 1959-60 Cars with Coil Springs, except that pipe must be disconnected from air spring to relieve pressure.*

UPPER CONTROL ARM (1958-60 COIL SPRING CARS):

Removal - Place jack under lower control arm and raise wheel off floor, then remove wheel. Remove ball stud from steering knuckle using Tool J-6627, then remove bolts and self-locking nuts holding control arm shaft to frame and remove control arm. Remove shaft from arm by removing front and rear threaded bushings.

UPPER CONTROL ARM (1958 AIR SUSPENSION CARS):

Removal - Raise front of car so wheels are off floor, then remove wheel. Disconnect pipe at spring to relieve air pressure. Disconnect upper ball stud at steering knuckle *(see "Coil Spring Cars" above)*, then disconnect control arm shaft from frame bracket noting number and location of shims found between shaft and frame bracket. Remove bushing from each end of shaft, then thread bolt into one end of control arm shaft and rest opposite end of arm on bed of press, and press shaft from upper end of arm (shoulder on shaft will force lower bushing from arm). *NOTE - If rubber of lower bushing tends to shear, insert 7/16" diameter pin through lower shaft attaching hole, then with 1/8" washer on pin at each end of shaft, press bushing from arm.* Remove bushing from shaft, then press remaining bushing from arm in same manner.

UPPER CONTROL ARM (1959 AIR SUSPENSION CARS):

Removal - *NOTE - Removal and installation procedures are the same as for 1959-60 Cars with Coil Springs.*

Installation: Place Spreader, Tool J-7167 in position in arm and expand arms by tightening nut. Overall dimension to outside of control arm bushing bosses should be 9.920". Place shaft in control arm with new rubber bushings at outer ends. *NOTE - Position shaft in arm so flats of shaft bolting bosses are approximately perpendicular to arm.* Using bushing replacer cups, Tool J-7179, press bushings onto shaft and into control arm. Remove bushing installing tools, then attach control arm shaft to frame bracket, replacing same number of shims at bolts from which they were removed. Tighten bolts to 50-60 ft. lbs. Complete installation by reversing removal procedure.

UPPER & LOWER BALL JOINT: Removal - With control arm removed, chisel or drill heads of rivets retaining ball joint to control arm and drive out rivets, then remove ball joint assembly.

Checking Ball Joints: *NOTE - This procedure supersedes previous procedures and should be used whenever it is necessary to check ball joints.* Check and lubricate all ball joints, then raise car at lower control arm supporting outside of spring seat so upper control arm is not touching rebound bumper and front wheels are free from contact with lift or floor. Check movement of each front wheel by moving top and bottom of tire in and out. If travel at periphery of tire is greater than ¼", wear in front system is indicated. If wheel bearings or upper control arm shafts are not the cause of looseness, remove upper ball stud and disconnect upper control arm from steering knuckle. With joint properly lubricated, install a nut snug against upper ball joint and rotate ball in its socket with a torque wrench. If torque required is less than ½ ft. lbs. or more than 6 ft. lbs., the ball joint should be replaced. If excessive looseness still exists, disconnect lower ball stud from steering knuckle. Install a nut on lower ball joint stud and check for excessive wear by measuring end play which should be .035" to .045". If endplay is greater, replace ball joint.

Installation: Install new ball joint and retain in position with special bolts supplied with the new joints. *CAUTION - Use only special alloy bolts supplied with ball joint replacement kit.* Tighten nuts to 10-12 ft. lbs.

Tightening Specifications

	Ft. Lbs.
Ball Stud Nut (1958-60)	60-95

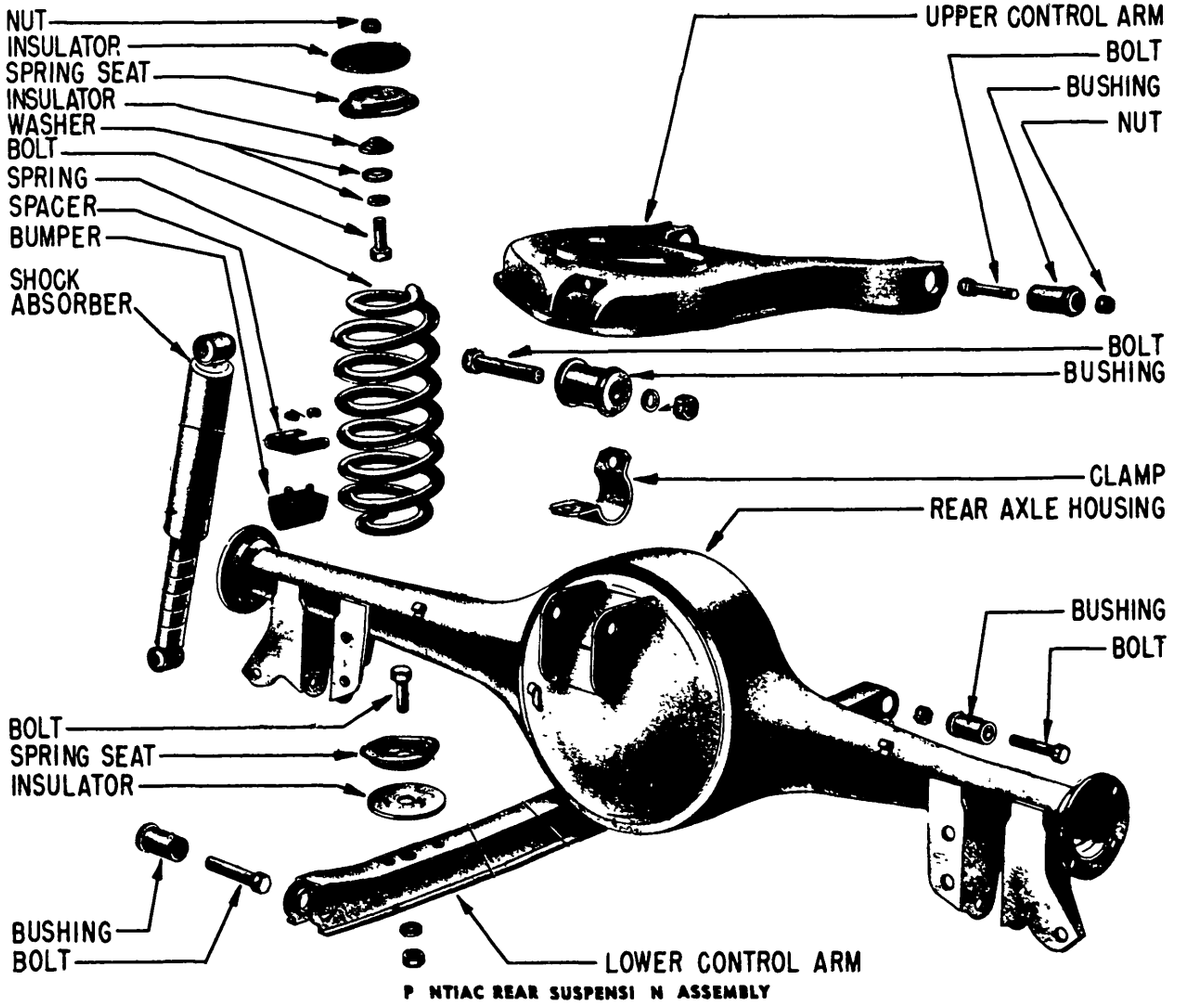
1958-60 PONTIAC REAR SUSPENSION

P ntiac (1958-60)

DESCRIPTION: Rear suspension linkage consists of two lower control arms and a single upper control arm. Forward ends of lower control arms are attached to brackets on frame crossmember and rear ends are attached to brackets welded to rear axle housing. Upper control arm is connected at two points to a frame crossmember and to a bracket welded to center of rear axle housing. Rubber bushings are used at all connecting points. Coil springs are mounted with lower end seated on lower control arm and upper end seated in tower in frame crossmember. *NOTE - With air suspension, coil springs ar r plac d by air springs in the same locati n.* On station wagon models, a rear stabilizer bar is mounted at rear of axle and is linked to frame.

LOWER CONTROL ARM & BUSHING: Removal - Remove pivot bolts at frame bracket and at rear axle housing. Press bushings out of control arm using Tools J-7022-1, J-7022-3 & J-7022-4 (1958-59); Tools J-8481-2, J-8481-3, J-8481-4 (1960), and an arbor press.



Installation: Install bushings using Tools J-7022-1, J-7022-2, J-7022-3, J-7022-4 (1958-59); Tools J-8481-1, J-8481-2, J-8481-3 (1960), and an arbor press.

UPPER CONTROL ARM & BUSHING: Removal - Remove pivot bolts at frame bracket and at rear axle housing. Press bushings out of control arm using Tool J-7022-1, 3 & 4 and an arbor press.

Installation: Install new bushings in control arm using the same tools as used for removal, then install control arm on frame and rear axle brackets. Tighten bolts as indicated in table below.

Tightening Specifications

Upper & Lower Arm Pivot Bolts	150-175
Coil Spring Upper Clamp Bolt	25-35
Coil Spring Lower Clamp Bolt	25-35
Rear Shock Absorber Bolts	50-65

P NTIAC REAR SUSPENSI N ASSEMBLY

REM VAL & INSTALLATI N

REAR COIL SPRINGS: Removal - *NOTE - For removal of rear air springs, see "Pontiac Air Suspension".* Raise car with chain fall until rear wheels are 8" off floor, then remove wheel assembly. Place car stand on floor jack under lower control arm spring seat and remove nut securing spring lower retainer. Remove pivot bolt from rear end of lower control arm, then raise car or lower jack as necessary to allow spring to expand. Remove upper retainer nut of spring and remove spring and retainers.

Installation: Reverse removal procedure and tighten bolts and nuts as indicated in table below.

Riding Height (1960 M d ls): 6" to 6½" measured from top of axle housing to frame at a point approximately 1½" outboard from rubber bumper on frame.

1954-60 STUDEBAKER & PACKARD

Studebaker (1954-60)
Packard (1957-58)

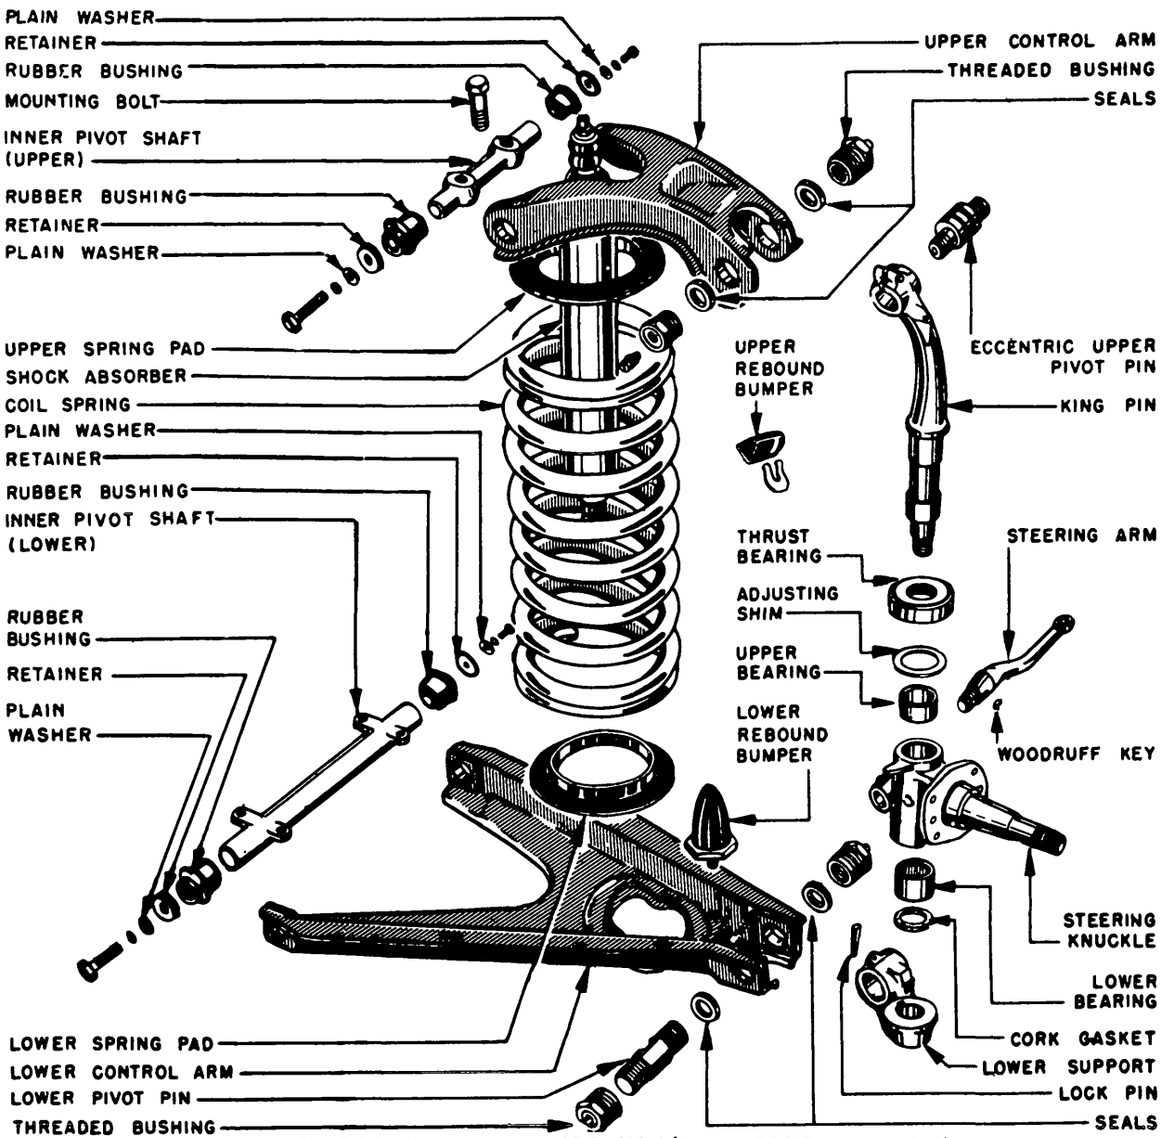
►CHANGES & CORRECTIONS

►*1955 CHUCKLING OR CRACKLING NOISE AT FRONT END CORRECTION:* Check lower support arm inner shaft attaching bolt nuts for tightness (black paint around inner shaft to crossmember contact area may be worn off or marked). Correct by removing the hug nuts one at a time. Place a hardened washer, Part No. 1539073 against the inner shaft boss and install new hug nuts. Tighten to 60-65 ft. lbs.

►*1955 SPEEDSTER MODEL FRONT SPRING SPACER PRODUCTION CHANGE:* Beginning with Car Serial No. 7166614, two spacers, Part No. 526830, are being installed on the left hand front spring as follows, to compensate for the greater load on that side. Install one spacer between front spring insulator and lower suspension arm. The other spring is installed between upper insulator and frame.

►*1957 CONTROL ARM BUSHING RETAINER PRODUCTION CHANGE:* Plain washers formerly installed on the control arm in shaft bushing retainer are no longer used in production. It is necessary and important that bushing retainer be torqued to proper specification (60-65 ft. lbs.).

►*1957 FRONT END NOISE CORRECTION (When Due to Looseness at Upper Control Arm Inner Shaft):* Can be caused by retaining screw having backed out, bushing retainer being worn and not holding inner sleeve of bushing, or bushing itself being worn. Inner side of retainer should have six serrations in good condition. Outside of retainer should not have pronounced galled spots from lockwasher. If retaining screw has worked loose, install a "Nylok" self-locking screw (Part No. 1541700). Also a plain washer, Part No. G446211, has been released to replace original lockwasher used in production. Tighten new screw to 35 ft. lbs. *CAUTION* - Under no circumstances should any lubricant be applied to bushing or retainer to eliminate a noise condition.



DESCRIPTION: Independent parallelogram type with coil springs. Shock absorbers are direct acting type mounted within front coil springs. Upper control arm outer pivot is eccentric and camber and caster adjustments are made at this point.

CHECKING & ADJUSTMENT: Before checking and adjusting front end alignment, check (and adjust if necessary) front wheel bearings, steering gear, steering arm and tie rod ends.

Tire Inflation: 1954-56 Models - Front - 26 lbs. **Rear** - 22 lbs. (Commander & President, Exc. Sta. Wgn.); 24 lbs. (Champion, All Models, & Commander Sta. Wgn.).
1957-58 Models - Front - 24 lbs. **Rear** - 20 lbs. (Exc. Sta. Wgn.); 24 lbs. (Sta. Wgn.).
1959-60 Models - Front - 24 lbs. (Exc. Sta. Wgn.); 26 lbs. (Sta. Wgn.). **Rear (5.90x15)** - 20 lbs. (Exc. Sta. Wgn.); 26 lbs. (Sta. Wgn.). **Rear (6.40x15)** - 20 lbs. (Exc. Sta. Wgn. & Taxi); 24 lbs. (Sta. Wgn. & Taxi). **R or (6.70x15)** - 20 lbs. (Exc. Sta. Wgn.); 24 lbs. (Sta. Wgn.).

►*CAPTIVE AIR TIRE NOTE:* **Front** - 24. lbs. **Rear** - 22 lbs.

Kingpin Inclination: 5¼° (1954-56); 6° (1957-60). At 0° camber.

STUDEBAKER FRONT SUSPENSION (RUBBER TYPE BUSHINGS)

Caster: Neg. 1° to Neg. 2½° (1954-58); Neg. 1½° to Neg. 3° (1959-60). There should not be more than ¾° variation between wheels. *NOTE - Adjust caster before making camber adjustment.* To adjust caster, loosen kingpin clamp bolt, then remove lubrication fitting from rear bushing at upper control arm outer pivot pin. Insert an Allen wrench into pin and turn until proper caster is obtained (one full turn will change caster ½°).

►*CAUTION:* Camber will be disturbed by caster adjustment unless pivot pin rotated in complete turns only.

Camber: 0° to Pos. 1° (½° greater camber desired on left side). To adjust camber (after caster adjustment completed), turn outer pivot pin, using an Allen Wrench to obtain desired setting. *NOTE - ½ turn of th pin covers entire range of camber adjustm nt.* Tighten clamp bolt and install lubrication fitting.

Toe-In: 1/16-1/8". Adjust as follows: With steering gear cam lever shaft on high spot of cam (steering wheel spoke straight down) and left front wheel in straight ahead position (adjust left hand tie rod to bring wheel into straight ahead position if necessary), adjust **right hand** tie rod to obtain desired setting.

CONTINUED ON NEXT PAGE

1954-60 STUDEBAKER & PACKARD (C ntinu d)

T -Out on Turns: As indicated in table below Not adjustable If incorrect, check for bent steering arm

M d l	Inn r Wheel	Outer Wheel
1954	23½°± 1°	20°
1955-57	22½ to 23½°	20 °
1958-60	23½° to 24½°	20°

FRONT COIL SPRING (1954-58): Removal - Raise car and support it with jack stands placed under frame at rear of engine rear support crossmember (be sure car is high enough for lower control arm to clear floor when released) Place a roller jack under center of lower control arm inner shaft and raise jack so it just contacts shaft Remove front shock absorber (see below), and disconnect stabilizer shaft from control arm Remove inner shaft-to-crossmember retaining bolts, then release jack slowly and lower control arm until spring is unloaded Remove jack and swing control arm outward, lifting spring off its seat Remove rubber spring pad from control arm

Installation: Place shock absorber mounting bolt in position on lower control arm, then place lower spring pad on spring seat Position spring on upper spring seat, and while holding spring so that it remains seated, swing control arm inward, seating spring on control arm seat Position roller jack under center of inner shaft and slowly lift jack to compress spring Align holes in inner shaft and holes in crossmember flange with a drift pin, and continue to lift inner shaft until attaching bolts can be installed Tighten bolts to 75-80 ft lbs

FRONT COIL SPRING (1959-60): Removal - Raise car and support with jack stands under frame (be sure car is high enough for lower control arm to clear floor when released) Place a roller jack under extreme outer end of lower control arm (not under pin on steering knuckle) and raise car slightly to support control arm Remove shock absorber (see below), then remove wheel, brake drum and backing plate (do not disconnect brake hose) Remove upper rebound bumper and disconnect tie rod outer end from steering arm If so equipped, disconnect stabilizer from lower control arm Remove upper control arm inner shaft attaching bolts and loosen the two inner shaft bushing capscrews sufficently to allow shaft to turn Pull upper control arm outward and lower the jack and lower control arm until spring is free, then remove spring

Installati n: Place top of spring into crossmember and position lower end on lower control arm *CAUTION - Install spring with closer coils to top, and the lower coil nd toward c nt rlin of car Be sure lower coil is placed ov r lip of seat in lower control arm to prevent it slipping when compr ss d* Place roller jack under extreme outer end of lower control arm and slowly raise the jack *NOTE - Mak sure upp r control arm is clear of crossm mber whil jack is raised* With spring sufficiently compressed, position upper control arm on crossmember and use a drift to align inner shaft and crossmember bolt holes, then install capscrews Install nuts and tighten to 75-80 ft lbs *CAUTION - To pr v nt injury, us a wr nch for positioning and holding nuts A short piece of masking tape will hold washer and nut to wrench.* Replace rebound bumper and install backing plate, brake drum and wheel Connect tie rod and replace stabilizer (if so equipped) Install shock absorber and lower car to floor, then tighten upper control arm inner shaft bushing capscrews to 50-55 ft lbs

SHOCK ABSORBER: Removal - Remove nut from upper end of shock absorber, then remove lower attaching bolts at lower control arm Thread shock absorber out of spring through lower control arm

Installation: Reverse removal procedures and tighten attaching screws securely

LOWER CONTROL ARM (1954-60): Removal - Remove coil spring and shock absorber (see above) On 1959-60 models, remove lower control arm inner shaft-to-crossmember bolts and remove arm from frame On all models, remove threaded bushings from outer end of control arm and remove tapered lockpin through outer pin by driving it upward with a pin punch Use a brass drift and drive outer pin out of steering knuckle support and remove control arm

Disassembly: To remove rubber bushings from control arms, place Tool J-5472-4 over one insulator and screw the ½" x 2½" capscrew into other end of shaft Turn inner shaft on control arm so that lugs on shaft contact outer shell of lower insulator, and install Tool J-5472-6 to prevent distortion of control arm Using an arbor press, move inner shaft down so that lugs on shaft contact outer shell of lower insulator Continue to press until outer shell is flush with flange on control arm Place control arm in a vise, gripping near the partly removed insulator, and knock the insulator the rest of the way out with a hammer and blunt chisel Remove capscrew from inner shaft and install it in other end of shaft, then using the same tools as for opposite end, remove second bushing in same manner.

Reassembly: Insert one end of inner shaft in one arm of lower control arm, then install opposite end in other arm. Place Tool J-5472-6 in position between ends of control arm Start rubber bushings in holes at either end of control arm, then place Tool J-5472-1 in position on each bushing, and using an arbor press, force both bushings in place until shoulder on outer sleeve of bushing is seated against control arm *(CAUTION - Do not attempt to seat flange of bushing on control arm).* Install bushing caps, flat washers, lockwashers, and capscrews *(NOTE* - Tighten these capscrews to 65 ft lbs. after control arm has been installed on car and weight of car is on springs)

Installation: *(NOTE - Outer ends of lower control arm must be spread .015" before installing outer pin and thr aded bushings. Determine this dimension by adjusting calipers to fit over outer end of control arm adjacent to bushing holes with a .015" f el r gaug inserted between outside surface of control arm and one prong of calipers).* After setting calipers, position outer end of lower control arm at lower steering knuckle support and install the outer pin, with a grease seal on pin on each side of steering knuckle support Using a screwdriver in slot provided in end of outer pin, turn pin and align slot at center of outer pin and hole of lower knuckle support and install lock pin Install spreader Tool J-2044 between inner surfaces of outer ends and spread the outer ends until the outside dimension is equal to caliper setting. Centralize outer end of control arm on outer pin, then install bushings and tighten to 170 ft lbs minimum. Remove spreader tool and make sure control arms turn freely on outer pin On 1959-60 models, connect lower control arm inner shaft to crossmember and tighten attaching bolts *NOTE - After weight of car is on springs, tighten lower control arm inn r shaft-to-crossmember attaching bolts to 65 ft. lbs* On all models, complete installation by installing coil spring (see above) *NOTE - If new bushings have been installed on inner shaft, tighten retaining capscrews to 60-65 ft lbs*

UPPER CONTROL ARM (1954-60): Removal - Support car at outer end of lower control arm. Remove front wheel assembly Remove threaded bushings from upper control arm outer pin Mark top front of inner shaft so that it can be installed in the same position *(CAUTION - Holes in control arm inner shaft are drilled off shaft centerline and turning the shaft over will change camb r setting).* Remove bolts and nuts retaining inner shaft to frame bracket (be careful not to drop bolts or nuts into front crossmember) Shift upper control arm to one side, turn the arm and lift it off end of pin, then remove arm by slipping it off other end of pin.
